The hydrochloride [$C_{17}H_{18}O_2N(OC_2H_5).HCl.2H_2O = 385.79$] of a synthetic alkaloid prepared from morphine by ethylation.

Preparation—It is prepared by subjecting morphine to the action of ethyl iodide in the presence of sodium or potassium hydroxide and purifying and salifying the resulting product.

Description and Physical Properties—A white or faintly yellow, microcrystalline powder, having no odor.

One Gm. of Ethylmorphine Hydrochloride is soluble in 8 cc. of water, and in 22 cc. of alcohol, at 25° C. It is slightly soluble in ether and in chloroform.

Tests for Identity—It melts at about 123° C. with decomposition.

Add a drop of ferric chloride T.S. to a solution of about 0.01 Gm. of the salt in 10 cc. of sulphuric acid, and warm it on a water bath: the mixture will become at first green, then deep violet-blue, and, after the addition of a drop of nitric acid, deep red.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate which is insoluble in nitric acid.

Tests for Purity—An aqueous solution of the salt (1 in 20) is neutral to litmus paper.

The ash from 0.2 Gm. is negligible.

Ethylmorphine Hydrochloride loses not more than 10 per cent of its weight when dried to constant weight at 100° C. (*water*).

Heat 5 cc. of an aqueous solution of the salt (1 in 20) with 5 cc. of sodium hydroxide T.S. on a water bath: no vapors showing an alkaline reaction to litmus paper are evolved at once (*ammonium compounds*).

Dissolve about 0.05 Gm. of potassium ferricyanide in 10 cc. of distilled water, add 1 cc. of diluted ferric chloride solution (1 volume of ferric chloride T.S. to 9 volumes of water), and 1 cc. of an aqueous solution of Ethylmorphine Hydrochloride (1 in 100): no green or blue color is produced at once (*morphine*).

Add 1 cc. of ammonia T.S. to 5 cc. of an aqueous solution of Ethylmorphine Hydrochloride (1 in 25): a white turbidity is produced at once (*difference from codeine hydrochloride*).

Preserve in well-closed containers, protected from light.

Uses—This alkaloid is commonly sold under the name *dionin*, and is used as a substitute for morphine, although it is less likely to cause nausea and depression. Dose. one-fourth grain (0.015 Gm.).

COTARNINÆ CHLORIDUM. U.S. Cotarnine Chloride

[**Cotarn. Chlor.**—COTARNINÆ HYDROCHLORIDUM U.S.P. IX]

The chloride [$C_{12}H_{14}O_3NCl.H_2O = 273.66$] of an alkaloid prepared from narcotine.

Preparation—The base was obtained by Wöhler by the oxidation of narcotine with manganese dioxide, in the presence of sulphuric acid. It can be readily made by oxidizing narcotine with nitric acid or by boiling narcotine with water until hydrolized.

Description and Physical Properties—A yellow, odorless, crystalline powder. It is deliquescent in moist air.

Cotarnine Chloride is very soluble in water and in alcohol, the solutions being yellow.

Tests for Identity—Dissolve about 0.5 Gm. of Cotarnine Chloride in 10 cc. of distilled water, and add 2 cc. of a 15 per cent aqueous solution of sodium hydroxide: a milk-white precipitate is produced which dissolves on agitation, but is reprecipitated from the solution after standing for some time, leaving the supernatant liquor clear but faintly yellow.

Silver nitrate T.S. added to an aqueous solution of Cotarnine Chloride produces a white precipitate insoluble in nitric acid.

About 0.2 Gm. of Cotarnine Chloride dissolved in 10 cc. of distilled water yields a brown precipitate of cotarnine periodide on the addition of 10 cc. of tenth-normal iodine. When this precipitate is collected on a filter, and dried to constant weight over sulphuric acid, it melts between 142° and 144° C.

Tests for Purity—An aqueous solution of Cotarnine Chloride (1 in 20) is neutral to litmus paper.

Heat gradually 0.1 Gm. of Cotarnine Chloride over a Bunsen burner: it is decomposed, evolving characteristic, disagreeable vapors and yielding a reddish-brown liquid, which gradually changes to a hard, charred mass. The ash remaining on the incineration of this mass is negligible.

Uses—It is used to check bleeding from small blood vessels, in certain forms of nose bleeding and slow hemorrhages. It is known commercially as *stypticin*, and cotarnine phthalate as *styptol*. Dose, one grain (0.06 Gm.).

Unofficial Opium Principles, Derivatives and Preparations

OPIUM DEODORATUM (U.S.P. IX) Deodorized Opium

Deodorized Opium yields not less than 10 per cent nor more than 10.5 per cent of anhydrous morphine.

Prepare by macerating 500 Gm. of powdered opium for twenty-four hours in a wide-mouthed, well-closed bottle with sufficient purified petroleum benzin to cover it completely, shaking the mixture occasionally. Then decant the clear benzin layer as closely as possible and repeat the maceration for twenty-four hours with another portion of purified petroleum benzin. Again decant the clear benzin layer and transfer the remaining contents of the bottle to a plain filter. Closely cover the funnel, allow the mixture to drain and then slowly percolate the residue with purified petroleum benzin until the latter passes through without color. Remove the filter containing the Opium from the funnel, expose the powder to the open air, so that it may dry thoroughly, and add sufficient sugar of milk to restore the original weight. Care should be used to guard against the danger due to the inflammability of the benzin. Granulated opium may also be deodorized in the manner directed above.

Assay—Proceed as directed under *Opium*.

Pantopon-Roche—*Pantopium Hydrochloricum*, N. N. R.—A mixture of the hydrochlorides of the alkaloids of opium in the proportion in which they exist in Smyrna opium, containing 50 per cent of anhydrous morphine hydrochloride.

Pantopon-Roche (pantopium hydrochloricum) is a yellowish-gray, crystalline powder which is readily soluble in water.

Uses—Pantopon produces essentially the effects of opium, but, being devoid of its extractive, it may be used for hypodermic administration. It is probably absorbed rather more promptly, and is free from the nauseant odor and taste of the ordinary opium preparations. It is used in the same conditions as those in which opium is indicated.

Dose—For adults, $\frac{1}{12}$ to $\frac{1}{3}$ grain (0.005 to 0.02 Gm.) hypodermically or by mouth. One grain of pantopon is equivalent to:

2.5 grains of extract of opium, U. S. P.
5.0 grains of powdered opium, U. S. P.
45.0 minims of tincture of opium, U. S. P.
0.6 grain of morphine sulphate, U. S. P.

Manufactured by F. Hoffmann-LaRoche and Company.

Papaverine—*Papaverina*, N. N. R.—$C_{20}H_{21}O_4N$.—An alkaloid obtained from opium, belonging to the benzyl iso-quinoline group (that is, it is not a morphine derivative).

In fine, white, rhombic prisms or needles or sometimes in scales; it is odorless and tasteless. It is nearly insoluble in cold water; slightly soluble in alcohol, ether, chloroform and benzene, if cold; somewhat more soluble in these liquids when hot, but deposited by them on cooling, and soluble in warm petroleum ether and in acetone. It melts at 147° C.

Uses—Papaverine relaxes smooth muscle in general, although different organs are affected in a varying degree.

Papaverine is most effective in hypertonic conditions, while it does not interfere materially with the normal movements, for instance, of the intestines. It is also a rather feeble central analgesic and a local anesthetic. Its toxicity is low, and neither tolerance nor habituation has been reported. These actions have prompted its use, with reported success, in various spasmodic conditions of the smooth muscles, especially in all kinds of gastric and intestinal spasms, in biliary colic, and in bronchial spasm.

Dose—The oral and hypodermic single dose is from $\frac{1}{2}$ to $\frac{1}{4}$ grain (0.03 to 0.02 Gm.); daily dose to $7\frac{1}{2}$ grains (0.5 Gm.). Single doses of even 15 grains (1 Gm.) are said to be non-toxic.

Papaverine Hydrochloride—*Papaverinæ Hydrochloridum*, N. N. R.—$C_{20}H_{21}O_4N.HCl$.—The hydrochloride of the alkaloid papaverine, containing no less than 88 per cent of papaverine.

Uses and Dose—See Papaverine.

Papaverine hydrochloride occurs in a fine, white, crystalline powder or in small monoclinic plates or prisms; odorless and having a bitter taste; permanent in the air. It is sparingly soluble in water; soluble in alcohol; very soluble in chloroform, and insoluble in ether. An aqueous solution of papaverine hydrochloride has an acid reaction toward litmus paper.

CINCHONA. U. S. Cinchona

[Cinch.—Yellow Cinchona, Calisaya Bark, Peruvian Bark]

Cinchona is the dried bark of *Cinchona succirubra* Pavon or of its hybrids, known in commerce as Red Cinchona, or of *Cinchona Ledgeriana* Moens, *Cinchona Calisaya* Weddell and of hybrids of these with other species of *Cinchona*, known in commerce as Calisaya Bark or Yellow Cinchona (Fam. *Rubiaceæ*).

Cinchona yields not less than 5 per cent of the alkaloids of Cinchona.

The value of cinchona bark depends entirely upon the percentage of alkaloids present in it; and as barks are found in the market greatly varying in quality, it is necessary to prove their worth by assay. The official description and assay are as follows:

Description—In quills or curved pieces or in broken fragments; bark from 2 to 8 mm. in thickness; externally brown or reddish-brown, usually with white or gray lichens, more or less roughened with corky ridges or protuberances, and with transverse fissures, rarely numerous or much intersected and having their sides sloping (*Red Cinchona*), or with numerous intersecting transverse and longitudinal fissures having nearly vertical sides (*Yellow Cinchona*); inner surface brown or reddish-brown and striate; fracture short and granular in the outer bark, rather splintery in the inner bark; odor faintly aromatic; taste astringent and very bitter.

For further description see the U. S. P. X.

Assay—Heat 5 Gm. of Cinchona, in fine powder, for one hour, in a 500 cc. flask on a water bath, with 5 cc. of diluted hydrochloric acid and 10 cc. of distilled water. Cool, add 200 cc. of ether-chloroform mixture, and 10 cc. of strong ammonia T.S. Proceed by Type Process A, decanting an aliquot portion of 160 cc., representing 4 Gm. of Cinchona, and determine the alkaloids gravimetrically. Use chloroform for the final extraction.

This assay is explained on page 1497.

U. S. P. Preparations—Fluidextractum Cinchonæ; Tinctura Cinchonæ; Tinctura Cinchonæ Composita.

History—This drug derives its name from the Countess of Chinchon, through whose instrumentality it was introduced into European medical prac-

tice in 1640. It was also called *Jesuit's Bark* in recognition of the fact that it was used by the members of this ecclesiastical order in treating fever and ague. Its adoption as a valuable official remedy followed the purchase by Louis XIV, in 1680, of the secret of a proprietary remedy sold by an English apothecary's clerk named Robert Talbor, which contained cinchona as a basis. The romance of Cinchona has been published in various books and is well worth perusal.

About twenty alkaloids have been discovered in cinchona barks. Some of these are found in only one kind of bark, some are doubtless " split products " —that is, not existing naturally in the bark, but the result of the action of chemical agents upon it.

Quinine, Quinidine, Cinchonine, and *Cinchonidine* are the most important alkaloids found in cinchona barks, and they, or their important salts, will be considered in separate articles. The acids present are *kinic,* or *quinic, quinotannic,* and *kinovic,* or *quinovic.* The neutral principle is *kinovin,* or *quinovin,* while *cinchonic-red,* volatile oil, and red and yellow coloring matter are also present. The first four of the alkaloids in the following list are used in medicine. The list is as follows:

Natural Alkaloids—Quinine, $C_{20}H_{24}O_2N_2$; Quinidine, $C_{20}H_{24}O_2N_2$; Cinchonine, $C_{19}H_{22}ON_2$; Cinchonidine, $C_{19}H_{22}ON_2$; Quinamine, $C_{19}H_{24}O_2N_2$; Conquinamine, $C_{19}H_{24}O_2N_2$; Homoquinine, $C_{39}H_{46}O_4N_4$; Cinchonamine, $C_{19}H_{24}ON_2$; Paytine, $C_{21}H_{24}ON_2.H_2O$; Homocinchonidine, $C_{19}H_{22}ON_2$; Cusconine, $C_{23}H_{28}O_4N_2$; Cusconidine, $C_{23}H_{28}O_4N_2$; Concusconine, $C_{22}H_{26}O_4N_2$; Aricine, $C_{23}H_{28}O_4N_2$; Paricine, $C_{16}H_{18}ON_2$; Paytamine, $C_{21}H_{24}ON_2$; Hydroquinine, $C_{20}H_{26}O_2N_2$; Hydroquinidine, $C_{20}H_{26}O_2N_2$; Cinchotine, $C_{19}H_{24}ON_2$; Hydrocinchonine, $C_{19}H_{24}ON_2$; Hydrocinchonidine, $C_{19}H_{24}ON_2$; Diquinidine, $C_{40}H_{46}O_3N_4$; Cupreine, $C_{19}H_{22}O_2N_2$.

The Artificial Alkaloids are: Quinicine, $C_{20}H_{24}O_2N_2$; Cinchonicine, $C_{19}H_{22}ON_2$; Quinamicine, $C_{19}H_{24}O_2N_2$; Apoquinamine, $C_{19}H_{22}ON_2$. These are chiefly produced by the action of heat upon the natural alkaloids and usually in the presence of diluted acids. In addition there have been many others made which are not of pharmaceutical interest.

One of the principal difficulties in preserving galenical preparations of cinchona arises from the alteration and precipitation which the cinchotannic acid and its compounds undergo upon keeping. Glycerin has proved to be very useful by dissolving and holding these in solution, and hence it is present in nearly every one of the preparations.

Uses—Cinchona is a febrifuge and tonic in doses of fifteen grains (1 Gm.).

QUININA. U. S. Quinine

[Quin.]

An alkaloid [$C_{20}H_{24}O_2N_2.3H_2O = 378.36$] obtained from cinchona.

In 1820 Pelletier and Caventou, the famous French pharmacists, investigated the alkaloid *cinchonine* which had been announced in 1811 by Gomez of Lisbon, and found it to be a mixture of two alkaloids, the second of which they named *quinine. Quinidine* was discovered by Henry in 1833 and *cinchonidine* by Winckler in 1844. Pasteur gave the latter alkaloid its name and discovered the artificial cinchona alkaloids *quinicine* and *cinchonicine.*

This alkaloid, the most important one of cinchona, was obtained in an impure state by Fourcroy in 1792, but the importance of the discovery or the identity or properties of the substance were not realized.

Preparation—This alkaloid is usually made by adding to the cooled acid solution of the sulphate a quantity of ammonia water or solution of sodium

hydroxide just sufficient to precipitate the quinine, carefully avoiding an excess.

Quinine is soluble to varying degrees in the organic solvents (see U. S. P. text) and it has an $[a]_D$ $-158°$ at 15° C. in 99 per cent alcohol. The specific rotation of the alkaloid and its salts vary with the solvent.

Description and Physical Properties—A white, microcrystalline, odorless powder. It has a bitter taste, which is intense and persistent. It is efflorescent in dry air.

One Gm. of Quinine is soluble in 1560 cc. of water, 0.8 cc. of alcohol, 1.1 cc. of chloroform, 1.9 cc. of ether, and in 1890 cc. of ammonia water, at 25° C. One Gm. is soluble in 800 cc. of boiling water.

Tests for Identity—An alcoholic solution of Quinine (1 in 10) is alkaline to litmus paper, and is lævorotatory.

A solution of Quinine in diluted sulphuric acid shows a vivid blue fluorescence. Add 2 or 3 drops of bromine T.S. to 5 cc. of a saturated aqueous, solution of Quinine and add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin.

Tests for Purity—Dried to constant weight at 100° C., Quinine loses not more than 15 per cent (*water*).

Ash: not more than 0.1 per cent.

A solution of 0.1 Gm. of Quinine in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

Heat 0.2 Gm. of Quinine with 2 cc. of sodium hydroxide T.S. on a water bath: the odor of ammonia is not evolved (*ammonium salts*).

Dry Quinine to constant weight at 100° C., dissolve 1.5 Gm. of the dried Quinine in 25 cc. of alcohol, dilute the solution with 50 cc. of hot water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other alkaloids* as directed under *Quininæ Sulphas*.

Preserve in well-closed containers, protected from light.

N. F. Preparations—Liquor Hypophosphitum Compositus; Oleatum Quininæ; Syrupus Ferri, Quininæ et Strychninæ Phosphatum; Syrupus Hypophosphitum Compositus.

Uses—The alkaloid quinine is usually an ingredient of preparations in which it remains undissolved and therefore tasteless. The Pharmacopœia gives the following dose: tonic, one and one-half grains (0.1 Gm.); antimalarial, at least fifteen grains (1 Gm.) daily.

QUININÆ SULPHAS. U.S. Quinine Sulphate

[Quin. Sulph.]

$[(C_{20}H_{24}O_2N_2)_2.H_2SO_4 = 746.69$ (with 7 or $8H_2O$).]

Preparation—The processes which are used for making quinine sulphate, commercially, are regarded as valuable trade secrets, and the manufacturers carefully guard them. The following process, which was formerly official, illustrates one method of making the sulphate of the principal alkaloid from cinchona:

Take of yellow cinchona, in coarse powder, 48 oz. troy; hydrochloric acid, 3½ oz. troy; lime in fine powder, 5 oz. troy; animal charcoal, in fine powder, sulphuric acid, alcohol, water, distilled water, each, a sufficient quantity. Boil the cinchona in 13 pints of water mixed with one-third of the hydrochloric acid, and strain through muslin. Boil the residue twice successively with the same quantity of water and acid as before, and strain. Mix the decoctions, and, while the liquid is hot, gradually add the lime, previously mixed with 2 pints of water, stirring constantly, until the quinine is completely precipitated. Wash the precipitate with distilled water, and, having pressed, dried, and powdered it, digest it in boiling alcohol. Pour off the liquid, and repeat the digestion several times, until the alcohol is no longer rendered bitter. Mix the liquids, and distil off the alcohol until a brown viscid mass remains. Upon this, transferred to a suitable vessel, pour 4 pints of distilled water, and, having heated the mixture to the boiling point, add as much sulphuric acid as may be necessary to dissolve the quinine. Then add 1½ oz. troy of animal charcoal, boil the liquid for two minutes, filter while hot, and set it aside to crystallize. Should the liquid, before filtration, be entirely neutral, acidulate it very slightly with sulphuric acid; should it, on the contrary, change the color of litmus paper to a bright red, add more animal charcoal. Separate the crystals from the liquid, dissolve them in boiling distilled water slightly acidulated with sulphuric acid, add a little animal charcoal, filter the solution, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper with a gentle heat, and keep them in a well-stoppered bottle. The mother-water may be made to yield an additional quantity of quinine sulphate by precipitating the quinine with ammonia water, and treating the precipitated alkaloid with distilled water, sulphuric acid, and animal charcoal, as before.

The hydrochloric acid forms with the alkaloids soluble hydrochlorides. The lime decomposes the salts by uniting with the acid, and the alkaloids are precipitated with the excess of lime. These are dissolved out with boiling alcohol, the solution evaporated, acidulated with sulphuric acid, decolorized with animal charcoal, and crystallized.

Sodium hydroxide is often used instead of lime to precipitate the alkaloids, because quinine is less soluble in a solution of sodium chloride than in calcium chloride, while several manufacturers prefer to use amyl alcohol for exhausting the lime precipitate of alkaloids. Oil of turpentine and refined petroleum have also been used as solvents to some extent.

At least three sulphates of quinine have been obtained, of which two are now official. The first of these, $(C_{20}H_{24}O_2N_2)_2.H_2SO_4 + 7H_2O$, "diquinic sulphate", is known and prescribed in Great Britain as *Quininæ Disulphas*, and is the official salt known as quinine sulphate, or *Quininæ Sulphas*, U. S.; the second, formed by dissolving the first in diluted sulphuric acid, has the formula $C_{20}H_{24}O_2N_2.H_2SO_4 + 7H_2O$, and is the official quinine bisulphate, or *Quininæ Bisulphas*, U. S.; while the third, which is not official, is the acid sulphate, $C_{20}H_{24}O_2N_2.2H_2SO_4 + 7H_2O$, and may be obtained from a solution of quinine in an excess of diluted sulphuric acid.

Description and Physical Properties—Hard, prismatic monoclinic needles or white, silky, light, flexible, glistening crystals, making a very light and easily compressible mass. It is odorless, and has a persistent, very bitter taste. It effloresces rapidly when exposed to dry air or when heated to 50° C., losing all but two molecules of its water of crystallization and becoming lusterless. When exposed to light, it acquires a brown tint.

One Gm. of Quinine Sulphate is soluble in 725 cc. of water, 107 cc. of alcohol, and in 30 cc. of glycerin, at 25° C. One Gm. is soluble in 47 cc. of water at 80° C. and in about 12 cc. of alcohol at 60° C. It is slightly soluble in chloroform and in ether, but is freely soluble in a mixture of 7 volumes of chloroform and in 4 volumes of dehydrated alcohol.

Tests for Identity—A saturated aqueous solution of Quinine Sulphate, when acidulated with diluted sulphuric acid, develops a vivid blue fluorescence.

Add 1 or 2 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000) and then add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin.

Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid.

Tests for Purity—A saturated aqueous solution of Quinine Sulphate is neutral or not more than slightly alkaline to litmus paper.

Quinine Sulphate loses not more than 16.2 per cent when dried to constant weight at 100° C. (*water*).

Ash: not more than 0.05 per cent.

A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

One Gm. of the salt dissolves completely when heated to 50° C. in 7 cc. of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol, and the solution remains clear on cooling (*inorganic salts*).

Dry Quinine Sulphate (which must be neutral or slightly alkaline to litmus paper) at 50° C. for two hours, and then agitate 1.8 Gm. of the dried salt with 20 cc. of distilled water at 65° C. for half an hour. Allow the mixture to cool to 15° C., macerate it at this temperature for two hours with occasional shaking, and then filter it through a filter paper of a diameter from 8 to 10 cm. Transfer 5 cc. of this filtrate to a test tube and mix it gently (without shaking) with 6 cc. of ammonia T.S., which must contain not less than 10 per cent and not more than 10.2 per cent of NH_3, have a temperature of 15° C., and be added at once. A clear liquid is produced (*other cinchona alkaloids*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Cinchonæ Alkaloidorum and in other Elixirs containing Cinchona alkaloids in combination with Iron, Bismuth, etc.; Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ; Pilulæ Antiperiodicæ; Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Fortiores; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Mites; Pilulæ Opii, Digitalis et Quininæ.

Uses—Quinine sulphate is used as an antiperiodic, tonic, and antipyretic. The tonic dose is one and one-half grains (0.1 Gm.), the anti-malarial dose, at least fifteen grains (1 Gm.) daily. It may be given in the form of pills or in solution. In the latter case it is better to suspend it in syrup without using acid, with the addition of a little fluidextract of glycyrrhiza and a small quantity of ammonia water.

QUININÆ BISULPHAS. U. S. Quinine Bisulphate

[**Quin. Bisulph.**—Quinine Acid Sulphate]

The acid sulphate $[C_{20}H_{24}O_2N_2.H_2SO_4.7H_2O = 548.50]$ of the alkaloid quinine.

Preparation—This salt is made by adding sulphuric acid to quinine sulphate suspended in water evaporating the solution, and crystallizing the bisulphate.

Description and Physical Properties—Colorless, transparent or whitish, orthorhombic crystals or small needles. It is odorless, and has a very bitter taste. It effloresces on exposure to air, and turns yellow on exposure to light.

One Gm. of Quinine Bisulphate is soluble in 9 cc. of water, 23 cc. of alcohol, 15 cc. of glycerin, 625 cc. of chloroform, and in 2500 cc. of ether, at 25° C. One Gm. is soluble in 0.7 cc. of boiling water and in 0.7 cc. of alcohol at 60° C.

Tests for Identity—An aqueous solution of Quinine Bisulphate (1 in 20) is strongly acid to litmus paper, and has a blue fluorescence.

Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of Quinine Bisulphate (1 in 1000), and then add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin.

Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid.

Tests for Purity—Quinine Bisulphate loses not more than 24 per cent when dried to constant weight at 100° C. (*water*).

Ash: not more than 0.05 per cent.

A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

Heat 0.3 Gm. of the salt with 3 cc. of sodium hydroxide T.S. on a water bath: the odor of ammonia is not evolved (*ammonium salts*).

Dissolve 2.52 Gm. of Quinine Bisulphate in a mixture of 20 cc. of alcohol and 50 cc. of hot distilled water, and neutralize the solution with normal sodium hydroxide, using 2 drops of methyl red T.S. as indicator. Evaporate the solution to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for other *cinchona alkaloids* as directed under *Quininæ Sulphas*.

Preserve in well-closed containers, protected from light.

Uses—The bisulphate has been introduced into medicine in preference to the ordinary sulphate, because of its greater solubility. Being about eighty times more soluble, it is better adapted for making into pills than is the sulphate. It contains about 15 per cent less of the alkaloid than does the sulphate. The difference is to some extent compensated for by the greater solubility, and the dose given is usually the same as that of the sulphate.

QUININÆ HYDROCHLORIDUM. U.S. Quinine Hydrochloride

[Quin. Hydrochl.]

The hydrochloride [$C_{20}H_{24}O_2N_2.HCl.2H_2O = 396.81$] of the alkaloid quinine.

Preparation—Quinine hydrochloride may be made by double decomposition between quinine sulphate and barium chloride, or by dissolving the alkaloid quinine in diluted hydrochloric acid, evaporating, and crystallizing.

Description and Physical Properties—White, silky, glistening needles. It is odorless, and has a very bitter taste. The salt effloresces when exposed to warm air.

One Gm. of Quinine Hydrochloride is soluble in 16 cc. of water, 0.8 cc. of alcohol, 7 cc. of glycerin, 0.7 cc. of chloroform, and in 340 cc. of ether, at 25° C. One Gm. is soluble in 0.5 cc. of water at 80° C.

Tests for Identity—Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of Quinine Hydrochloride (1 in 1000), and then add 1 cc. of ammonia T.S.: an emerald-green color is produced, due to the formation of thalleioquin.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate insoluble in nitric acid, but soluble in ammonia T.S.

Tests for Purity—An aqueous solution of Quinine Hydrochloride (1 in 25) is neutral or not more than slightly alkaline to litmus paper, and is not fluorescent, except when highly diluted or when diluted sulphuric acid is added to it.

Quinine Hydrochloride loses not more than 10 per cent when dried to constant weight at 120° C. (*water*).

Ash: not more than 0.05 per cent.

A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

One Gm. of the salt dissolves completely in 7 cc. of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol (*inorganic salts*).

The addition of 5 drops of diluted sulphuric acid to 10 cc. of an aqueous solution of the salt (1 in 20) produces no turbidity (*barium*).

One Gm. of Quinine Hydrochloride shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1520.

Dissolve about 2.5 Gm. of Quinine Hydrochloride in 60 cc. of distilled water in a separator, add 10 cc. of ammonia T.S., shake out the mixture successively with 30 and 20 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal

sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas*.

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Ferri, Quininæ et Strychninæ; Elixir Glycerophosphatum Compositum; Syrupus Phosphatum cum Quinina et Strychnina; Tinctura Antiperiodica; Tinctura Antiperiodica sine Aloe.

Uses—This salt is used like the sulphate but it is much more soluble. The dose is the same as for the sulphate.

QUININÆ DIHYDROCHLORIDUM. U. S. Quinine Dihydrochloride

[Quin. Dihydrochl.]

The dihydrochloride [$C_{20}H_{24}O_2N_2.2HCl = 397.24$] of the alkaloid quinine.

Preparation—It may be prepared by dissolving 100 parts of quinine hydrochloride in 200 parts of distilled water and adding 37 parts of 25 per cent hydrochloric acid, the amount required to produce the dihydrochloride.

Description and Physical Properties—A white, odorless powder, having a very bitter taste.

One Gm. of Quinine Dihydrochloride is soluble in about 0.6 cc. of water and in 12 cc. of alcohol, at 25° C. It is slightly soluble in chloroform and very slightly soluble in ether.

Tests for Identity—An aqueous solution of Quinine Dihydrochloride is strongly acid to litmus paper.

Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000), and then add 1 cc. of ammonia T.S.: an emerald-green color is produced, due to the formation of thalleioquin.

Silver nitrate T.S. added to an aqueous solution of the salt (1 in 20) produces a white precipitate, insoluble in nitric acid but soluble in ammonia T.S.

Tests for Purity—Quinine Dihydrochloride loses not more than 3 per cent when dried to constant weight at 100° C. (*water*).

Ash: not more than 0.05 per cent.

A solution of 0.1 Gm. of Quinine Dihydrochloride in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

The addition of a few drops of diluted sulphuric acid to 10 cc. of an aqueous solution of the salt (1 in 20) produces no turbidity (*barium*).

One Gm. of Quinine Dihydrochloride shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1520.

Dissolve 1.8 Gm. of Quinine Dihydrochloride in 10 cc. of distilled water, add a slight excess of ammonia T.S., shake out the mixture successively with 20, 10 and 10 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve the residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas*.

Preserve in well-closed containers, protected from light.

Uses—Its therapeutic effects are similar to the other quinine salts, but its great solubility makes it a favorite salt of quinine for hypodermic administration. The dose is the same as the sulphate.

QUININÆ HYDROBROMIDUM. U. S. Quinine Hydrobromide

[Quin. Hydrobr.—Quinine Bromide]

The hydrobromide [$C_{20}H_{24}O_2N_2.HBr.H_2O = 423.25$] of the alkaloid quinine.

Preparation—Quinine hydrobromide may be made by decomposing 40 parts of quinine sulphate, dissolved in 400 parts of hot alcohol, with 11 parts of potassium bromide dissolved in 30 parts of distilled water. Potassium sulphate crystallizes out, and the quinine hydrobromide in solution may be obtained by evaporation and crystallization. In drying the salt, care must be observed not to subject the crystals to heat sufficient to fuse them. A warm, dry atmosphere should be relied upon to effect the drying, and all unnecessary exposure to light should be avoided.

Quinine hydrobromide may also be made by double decomposition between quinine sulphate and barium bromide, both in hot alcoholic solution. It is sometimes made by dissolving the alkaloid quinine in hot diluted hydrobromic acid until the latter is no longer acid to litmus paper, evaporating, and crystallizing.

Description and Physical Properties—White, light, small needles, or scale-like crystals. It is odorless, has a very bitter taste, and effloresces on exposure to the air.

One Gm. of Quinine Hydrobromide is soluble in 40 cc. of water, 1 cc. of alcohol, 7 cc. of glycerin, 0.6 cc. of chloroform, and in 23 cc. of ether, at 25° C. One Gm. is soluble in 3.2 cc. of water at 80° C.

Tests for Identity—Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of Quinine Hydrobromide (1 in 1000), and then add 1 cc. of ammonia T.S.: an emerald-green color is produced, due to the formation of thalleioquin.

To 5 cc. of an aqueous solution of Quinine Hydrobromide (1 in 50) add 1 cc. of sodium hydroxide T.S., and warm the mixture for a few minutes. Cool well, filter, acidulate the filtrate with dilute hydrochloric acid, add 1 cc. of chloroform and a few drops of chlorine T.S., and shake gently: the chloroform acquires a reddish-brown color.

Tests for Purity—An aqueous solution of Quinine Hydrobromide (1 in 50) is neutral or only slightly alkaline to litmus paper and is not fluorescent except when mixed with an excess of diluted sulphuric acid.

Dried to constant weight at 100° C., Quinine Hydrobromide loses not more than 5 per cent (*water*).

Ash: not more than 0.05 per cent.

A solution of about 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

One Gm. of Quinine Hydrobromide shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid, page 1520.

The addition of a few drops of diluted sulphuric acid to 10 cc. of a hot aqueous solution of the salt (1 in 20) produces no turbidity (*barium*).

One Gm. of Quinine Hydrobromide dissolves completely in 7 cc. of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol (*inorganic salts*).

Dissolve about 3 Gm. of Quinine Hydrobromide in 80 cc. of warm distilled water in a separator, add 10 cc. of ammonia T.S., shake out the mixture successively with 30 and 20 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas*.

Preserve in well-closed containers, protected from light.

Uses—Quinine hydrobromide is sometimes used hypodermically. Its dose is the same as that of the sulphate.

QUININÆ TANNAS. U. S. Quinine Tannate
[Quin. Tann.]

Quinine Tannate is a compound of quinine with tannic acid, of somewhat varying composition, corresponding to not less than 30 per cent and not more than 35 per cent of anhydrous quinine [$C_{20}H_{24}O_2N_2 = 324.31$].

Preparation—It may be prepared by dissolving 12 Gm. of tannic acid in 75 cc. of distilled water and pouring the solution slowly and with constant stirring into a solution of 10 Gm. of quinine sulphate in a mixture of 15 cc. of diluted sulphuric acid and 150 cc. of water. Three Gm. of tannic acid and 3 Gm. of sodium bicarbonate are each dissolved in 50 cc. of distilled water, the solutions filtered and mixed, and the mixture added to the quinine-tannin mixture first prepared. The resulting precipitate is collected on a strainer, washed, heated on a water bath, in a porcelain dish, until it becomes resin-like, and is finally dried in the air and powdered.

Description and Physical Properties—A pale yellow or yellowish-white, amorphous powder. It is odorless and tasteless, or has not more than a slightly bitter, astringent taste.

Quinine Tannate is only slightly soluble in water, chloroform, and ether. It is somewhat more soluble in alcohol.

Tests for Identity—When heated, it melts to a purplish, viscous mass.

A saturated aqueous or alcoholic solution of Quinine Tannate is colored blue-black by ferric chloride T.S.

The alkaloid obtained in the assay responds to the identity tests under *Quinina*.

Tests for Purity—Quinine Tannate loses not more than 10 per cent when dried to constant weight at 100° C. (*water*).

Ash: not more than 0.3 per cent.

Shake 0.5 Gm. of Quinine Tannate with 50 cc. of distilled water and 1 cc. of nitric acid for five minutes, and filter: a 10 cc. portion of the filtrate is not colored by 1 cc. of hydrogen sulphide T.S. (*heavy metals*). Other 10 cc. portions of the filtrate show no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid and no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid.

Shake 1 Gm. of Quinine Tannate with 25 cc. of dehydrated ether for five minutes, filter, and wash the filter with 10 cc. of dehydrated ether. Evaporate the combined filtrate and washings and dry at 100° C.: the residue does not exceed 1 per cent (*uncombined quinine*).

Assay—Transfer to a separator about 0.5 Gm. of Quinine Tannate, accurately weighed, add 10 cc. of distilled water and 10 cc. of ammonia T.S., and shake at first with 20 cc. of ether, then with three successive 10 cc. portions of ether. Evaporate the combined ethereal liquids and dry the residue to constant weight at 100° C. The weight of the anhydrous quinine ($C_{20}H_{24}O_2N_2$) so obtained corresponds to not less than 30 and not more than 35 per cent of the weight of the Quinine Tannate taken.

Preserve in well-closed containers, protected from light.

Uses—This salt of quinine is almost insoluble in water and consequently almost tasteless. It is less certain in its action than the more soluble salts. Dose, three grains (0.2 Gm.).

QUININÆ ÆTHYLCARBONAS. U. S. Quinine Ethylcarbonate

[Quin. Æthylcarb.—Euquinine]

Quinine Ethylcarbonate [$C_2H_5O.CO.O.C_{20}H_{28}N_2O = 396.36$], the quinine ester of ethyl carbonic acid.

Description and Physical Properties—White, fine, soft needles, usually matted together in fleecy masses. Quinine Ethylcarbonate is odorless and practically tasteless, but when masticated it slowly develops a slightly bitter taste. It darkens on exposure to light.

Quinine Ethylcarbonate is only slightly soluble in water. One Gm. is soluble in 2 cc. of alcohol, 1 cc. of chloroform, and in about 10 cc. of ether, at 25° C. It is readily soluble in dilute acids.

Tests for Identity—Quinine Ethylcarbonate melts between 89° and 91° C.

Its saturated aqueous solution is slightly alkaline to litmus paper.

Its solution in diluted sulphuric acid exhibits a blue fluorescence.

To 5 cc. of an aqueous solution of Quinine Ethylcarbonate (1 in 1000), made with the aid of a slight excess of diluted sulphuric acid, add 2 or 3 drops of bromine T.S., and follow with 1 cc. of ammonia water: the liquid acquires a green color, due to the formation of thalleioquin.

To about 0.2 Gm. of Quinine Ethylcarbonate add 2 cc. of sodium hydroxide T.S. and 5 cc. of iodine T.S., and gently warm the mixture: the odor of iodoform is evolved.

Digest about 1 Gm. of Quinine Ethylcarbonate with 10 cc. of a 5 per cent solution of potassium hydroxide in dehydrated alcohol: a white precipitate is gradually formed which effervesces with acids.

Tests for Purity—Ash: not more than 0.2 per cent.

Dried over sulphuric acid for twenty-four hours, the loss in weight does not exceed 2 per cent (*water*).

Dissolve 0.3 Gm. of Quinine Ethylcarbonate in 10 cc. of diluted nitric acid and 20 cc. of distilled water: ten cc. portions of this solution are not rendered turbid at once by the addition of a few drops of silver nitrate T.S. (*chloride*) or of barium chloride T.S. (*sulphate*).

Preserve protected from light.

Uses—The action of quinine is essentially the same in all of its compounds. The soluble salts have the disadvantage of the bitter taste, and of producing a local action on the stomach and other tissues. To obviate these difficulties, insoluble compounds like the alkaloid, the tannate or the ethylcarbonate have been used, since these pass the mouth and stomach without offending the taste or disturbing the stomach. The same object is obtained more or less completely in a number of synthetic compounds in which the quinine radical is combined with other radicals, such as those of carbonic acid, to form insoluble, and therefore tasteless, esters. In the intestines these esters are broken up more or less rapidly into the alkaloid quinine and the other components. The rapidity with which this decomposition occurs will determine to a large extent the intensity of the therapeutic effect and the liability to produce cinchonism. This new official ester is of the latter character. The uses and dose are the same as for the other quinine salts.

QUININÆ ET UREÆ HYDROCHLORIDUM. U. S. Quinine and Urea Hydrochloride

[Quin. et Urea. Hydrochl.—Quinine and Urea Chloride]

A compound of the hydrochlorides of quinine and urea [$C_{20}H_{24}O_2N_2.HCl.CO(NH_2)_2.HCl.5H_2O = 547.38$] contains not less than 58 per cent of anhydrous quinine [$C_{20}H_{24}O_2N_2$].

Preparation—It may be prepared by dissolving 40 parts of quinine hydrochloride in 30 parts of diluted hydrochloric acid, specific gravity 1.061, adding 6 to 6.1 parts of pure urea, warming to form a solution filtering through glass wool, and crystallizing.

Description and Physical Properties—Colorless, translucent prisms, or a white, granular powder. It is odorless, and has a very bitter taste.

One Gm. of Quinine and Urea Hydrochloride is soluble in 0.9 cc. of water and in 2.4 cc. of alcohol, at 25° C.

Tests for Identity—An aqueous solution of Quinine and Urea Hydrochloride (1 in 20) is strongly acid to litmus paper.

A solution of the salt in diluted sulphuric acid (1 in 1000) shows a blue fluorescence. Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000), and then add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin.

Add 2 cc. of colorless nitric acid to a cold solution of about 1 Gm. of the salt in 2 cc. of distilled water and cool the mixture at once to the temperature of melting ice: crystalline leaflets of urea nitrate are formed on standing. Collect the crystals in a funnel upon glass wool, wash them with about 5 cc. of a cold mixture of equal volumes of nitric acid and distilled water, and after draining, dissolve the crystals in a few cc. of distilled water: the addition of a few drops of mercuric nitrate T.S. to the urea nitrate solution, followed by sodium hydroxide T.S. to only a slightly acid reaction, produces a white precipitate.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate, insoluble in nitric acid but soluble in ammonia T.S.

Tests for Purity—Ash: not more than 0.05 per cent.

A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

Warm 10 cc. of an aqueous solution of the salt (1 in 20) with 5 cc. of sodium hydroxide T.S. to 50° C.: the odor of ammonia is not evolved at once (*ammonium compounds*).

Dissolve about 3 Gm. of Quinine and Urea Hydrochloride in 30 cc. of distilled water in a separator, add 10 cc. of ammonia water, shake out the mixture successively with 30 and 20 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas*.

Assay—Dissolve about 0.5 Gm. of Quinine and Urea Hydrochloride, accurately weighed, in 5 cc. of distilled water in a separator, add 3 cc. of ammonia T.S., and shake the mixture with successive portions of 10, 5 and 5 cc., respectively, of chloroform or sufficient to completely extract the quinine. Evaporate the combined chloroform solutions on a water bath, dissolve the residue in 10 cc. of ether, evaporate to dryness and dry to constant weight at 100° C. The residue of anhydrous quinine ($C_{20}H_{24}O_2N_2$) so obtained corresponds to not less than 58 per cent of the weight of the Quinine and Urea Hydrochloride taken.

This assay is explained on page 1476.

Preserve in well-closed containers, protected from light.

Uses—It is used hypodermically in fifteen grain (1 Gm.) daily doses in the treatment of malaria and pneumonia. It is also much used as a local anesthetic as a substitute for cocaine.

Unofficial Salts of Quinine

Quininæ Hypophosphis, $C_{20}H_{24}O_2N_2HPH_2O_2.2H_2O$. (Quinine Hypophosphite (N. F. IV)	Fine, white, needles: odorless; very bitter. Soluble in about 35 parts of water and in 12.5 parts of alcohol. Dose, the same as other quinine salts
Quininæ Valeras, $C_{20}H_{24}O_2N_2HC_5H_9O_2.H_2O$. Quinine Valerate (N. F. IV)	White, lustrous crystals having an odor of valeric acid. Sparingly soluble in water but readily soluble in alcohol
Quininæ Glycerophosphas, $(C_{20}H_{24}O_2N_2)_2PO_4H_2(C_3H_7O_2).4H_2O$ Quinine Glycerophosphate, (N. F. IV)	White, crystalline needles or a powder. Soluble in about 850 parts of water and 75 parts of alcohol. Dose, the same as for quinine sulphate

Unofficial Salts of Quinine—*Continued*

Quininæ Salicylas, $C_{20}H_{24}O_2N_2.C_7H_6O_3.H_2O$. Quinine Salicylate (U. S. P. IX).	The salicylate of the alkaloid quinine. Colorless needles becoming pink on keeping. Soluble in 14 parts of alcohol, only slightly soluble in water. Dose, the same as the sulphate
Aristochin, Diquinine Carbonic Ester	The neutral carbonic ester of quinine. It is almost tasteless and insoluble
Saloquin, Quinine Salicylic Ester (Salochinin)	The salicylic acid ester of quinine. A tasteless salt of quinine

QUINIDINA. N. F. Quinidine

[Quinid.]

An alkaloid [$C_{20}H_{24}O_2N_2 = 324.31$], isomeric with quinine, obtained from the bark of various species of *Cinchona* (Fam. *Rubiaceæ*).

Quinidine (*conquinine*) is an isomer of quinine and occurs at least in small quantities in all of the cinchonas. It is probably present to the largest extent in Cinchona Calisaya which often contains 3 per cent.

It occurs in the mother liquors from the preparation of quinine sulphate. These liquors are precipitated with sodium hydroxide, whereby a mixture of alkaloids, known as "*quinoidine*" or "*chinoidin*", is obtained. This is similar to what is known as "*cinchona febrifuge*", which is prepared in India for native distribution. The quinoidine is extracted with ether, which removes the cinchonidine and quinidine. The ethereal solutions are evaporated, taken up in sulphuric acid, neutralized with ammonia, and the cinchonidine precipitated as the tartrate. Quinidine is a diacidic base, it produces fluorescence similar to quinine and gives the thalleioquin test. It is dextrorotatory $[\alpha]_D + 274.7°$ in a mixture of alcohol, 1 volume, chloroform, 2 volumes; quinine is lævorotatory.

Official Description—Quinidine occurs in acicular white crystals or as an amorphous white powder. When crystallized from alcohol it forms monoclinic prisms containing one molecule of alcohol, which it slowly loses on exposure to air, and rapidly loses when heated to 100° C. When precipitated by ammonia water from an aqueous solution of a salt of Quinidine, washed and dried, it forms an amorphous powder.

Odor, Taste—Odorless and having an intense and persistent bitter taste.

Solubility—When crystallized from an alcoholic solution, 1 Gm. dissolves at 25° C. in about 32 cc. of alcohol, 53 cc. of ether, and 1.5 cc. of chloroform; very slightly soluble in petroleum benzin and almost insoluble in water.

One gram of dried amorphous Quinidine dissolves at 25° C. in about 36 cc. of alcohol, 67 cc. of ether, and 1.7 cc. of chloroform; very slightly soluble in petroleum benzin and almost insoluble in water.

Tests for Identity—Quinidine melts at about 168° C. Incinerate 0.2 Gm. of Quinidine; no weighable residue remains.

Its alcoholic solution is dextrorotatory and its aqueous solution is alkaline to litmus.

A solution of Quinidine in diluted sulphuric acid (1 in 1000) shows a strong blue fluorescence.

Add a few drops of bromine T.S. to 10 cc. of an aqueous solution of Quinidine (1 in 1000), made with the aid of sufficient diluted sulphuric acid to produce complete solution, and then follow with ammonia water in slight excess; the liquid acquires an emerald-green color.

A solution of about 0.1 Gm. of Quinidine in 5 cc. of sulphuric acid is not darker than pale yellow.

Impurities and Tests for Impurities—Dissolve 0.5 Gm. of Quinidine in 10 cc. of distilled water at 80° C., with just enough sulphuric acid to form a solution neutral to litmus paper, and add a neutral solution of 0.5 Gm. of potassium iodide in 5 cc. of distilled water at 80° C. Agitate the mixture slightly, cool it to 15° C. and keep it at this temperature for one hour with occasional stirring. A white precipitate is formed (*difference from quinine*).

Filter out the precipitate and add 2 drops of ammonia water to the filtrate: it does not cause more than a slight turbidity (*other cinchona bases*).

Care must be taken to have the liquid perfectly neutral after the addition of the potassium iodide solution; if slightly acid, very dilute ammonia water must be added, drop by drop, with constant stirring, until exactly neutral to litmus paper.

Preserve in well closed containers, protected from light.

N. F. Preparation—Syrupus Quinidinæ.

Uses—Because of sparing solubility in water it is directed in the N. F. to prepare what has been sold as a "*Tasteless Syrup of Quinidine*". The dose is the same as quinine sulphate.

QUINIDINÆ SULPHAS. U. S. Quinidine Sulphate

[Quinidin. Sulph.]

The sulphate [$(C_{20}H_{24}O_2N_2)_2.H_2SO_4.2H_2O = 782.72$] of an alkaloid obtained from cinchona.

Preparation—Quinidine is obtained from cinchona bark as a by-product in the manufacture of quinine, to which it is closely related, being the stereoisomer of quinine.

Description and Physical Properties—Fine, needle-like, white crystals, frequently cohering in masses. It is odorless, has a very bitter taste, and darkens on exposure to light.

One Gm. of Quinidine Sulphate is soluble in about 90 cc. of water, and in 10 cc. of alcohol at 25° C. One Gm. is soluble in about 15 cc. of boiling water. It is soluble in chloroform but almost insoluble in ether.

Tests for Identity—An aqueous solution of Quinidine Sulphate (1 in 100) is neutral or slightly alkaline to litmus paper, and is dextrorotatory. (Quinine sulphate is lævorotatory.)

An aqueous solution of Quinidine Sulphate, when acidulated with diluted sulphuric acid, develops a vivid blue fluorescence. Add 1 or 2 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000) and follow with 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color due to the formation of thalleioquin.

To 5 cc. of an aqueous solution of Quinidine Sulphate (1 in 100) add 1 cc. of silver nitrate T.S. and stir the mixture with a glass rod: a white precipitate forms after a short interval (*difference from many other alkaloids*).

Barium chloride produces in an aqueous solution of the salt a white precipitate which is insoluble in hydrochloric acid.

Tests for Purity—Dried to constant weight at 100° C., Quinidine Sulphate loses not more than 5 per cent (*water*).

Ash: not more than 0.1 per cent.

A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*).

One Gm. of Quinidine Sulphate dissolves in 5 cc. of a warm mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol with not more than a slight turbidity (*ammonium or other inorganic salts*).

Dissolve 0.5 Gm. of Quinidine Sulphate in 15 cc. of boiling water and add a solution of 0.5 Gm. of potassium iodide in 5 cc. of distilled water, which, if necessary, has previously been neutralized to litmus paper with tenth-normal sulphuric acid. A white precipitate is formed. Mix well, cool the mixture to 15° C., and keep it at this temperature for one hour with frequent agitation. Filter and add 2 drops of ammonia T.S. to the filtrate. No turbidity is produced within one minute (*other cinchona alkaloids*).

Preserve in well-closed containers, protected from light.

Uses—Quinidine, like quinine, is a protoplasm poison. It affects protozoa more than bacteria but less powerfully than quinine. At one time it was used, to some extent, as a substitute for quinine because it was then much the cheaper preparation.

Quinidine acts upon the heart in such a manner as to bring about cessation of fibrillation of the auricles in a certain proportion of instances. Quinidine and other cinchona alkaloids are the only drugs known to have this specific effect.

Dose—Commonly 3 grains (0.2 Gm.) of Quinidine Sulphate are given as a preliminary dose, and repeated after two hours to determine the patient's susceptibility to the drug. If there are no symptoms following this preliminary dose, therapeutic administration is begun on the following day when from 3 to 6 grains (0.2 to 0.4 Gm.) are given from three to five times daily, for one to three days. The maximum dose per day is from 15 to 30 grains (1 to 2 Gm.). If toxic symptoms occur, the administration of the drug should be discontinued.

CINCHONINÆ SULPHAS. N. F. Cinchonine Sulphate

(U. S. P. IX)

[Cinchonin. Sulph.]

The sulphate $[(C_{19}H_{22}ON_2)_2.H_2SO_4.2H_2O = 722.68]$ of an alkaloid obtained from the bark of several species of cinchona.

Cinchonine occurs in all of the varieties of cinchona, although it occurs in largest amounts in *Cinchona micrantha*. Due to the solubility of the sulphate it remains in the mother liquor after the crystallization of quinine sulphate. The liquor is precipitated with caustic soda producing, "quinoidine", a mixture of cinchonine, cinchonidine, and quinidine. The cinchonidine and quinidine are removed by washing with ether. The alkaloid is then crystallized from boiling alcohol.

Cinchonine is a diacidic base. It is not fluorescent in acid solution and does not give the thalleioquin reaction. It has an $[\alpha]_D$ of $+229°$ in alcoholic solution. It is isomeric with

cinchonidine but from which it differs by being nearly insoluble in ether and having a dextrorotatory power, whereas cinchonidine is lævorotatory.

Official Description—Cinchonine Sulphate occurs in white, lustrous prismatic crystals; odorless, and having a very bitter taste, permanent in the air.

Solubility—One Gm. of Cinchonine Sulphate dissolves in 60 cc. of water, 12.5 cc. of alcohol, 47 cc. of chloroform, and in 3230 cc. of ether at 25° C., also in 33 cc. of water at 80° C. and in 7 cc. of alcohol at 60° C.

Tests for Identity—A saturated aqueous solution of the salt is neutral or slightly alkaline to litmus and is dextrorotatory.

An aqueous solution of Cinchonine Sulphate (1 in 100) yields with barium chloride T.S. a white precipitate insoluble in hydrochloric acid.

Dried to constant weight at 100° C. Cinchonine Sulphate loses not more than 5 per cent of its weight.

Tests for Purity—Incinerate about 1 Gm. of Cinchonine Sulphate: not more than 0.1 per cent of ash remains.

Ten cc. of a solution of the salt (1 in 1000) in diluted sulphuric acid exhibits only a slight, blue fluorescence.

One-tenth Gm. of the powdered salt dissolves completely or nearly so when shaken with 10 cc. of chloroform at ordinary temperatures (*quinine or cinchonidine sulphate*).

Add 0.1 Gm. of the salt to 2 cc. of sulphuric acid; it imparts not more than a faint, yellow tinge to the acid (*readily carbonizable organic impurities*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Cinchonæ Alkaloidorum and in other elixirs containing cinchona alkaloids in combination with iron, bismuth, etc.

Uses—Cinchonine sulphate is used as a tonic and febrifuge. Its cheapness has led to its extensive employment as a substitute for quinine. The dose as an antiperiodic is, however, larger. The U. S. P. dose is two and one-half grains (0.15 Gm.), but fifteen to forty grains (1.0 to 2.6 Gm.) have been given.

CINCHONIDINÆ SULPHAS. U. S. Cinchonidine Sulphate

[Cinchonid. Sulph.]

The sulphate $[(C_{19}H_{22}ON_2)_2H_2SO_4.3H_2O = 740.70]$ of an alkaloid obtained from cinchona bark.

Preparation—The cinchonidine tartrate obtained in the manufacture of quinidine, is dissolved in dilute acid and then ammonia is added in excess. The precipitate is recrystallized from alcohol.

Cinchonidine behaves similarly to cinchonine in not being fluorescent and in not responding to the thalleioquin reaction. The base melts at 207° C. and has an $[a]_D$ of $-107.9°$ in 1 volume of alcohol, and in 2 volumes of chloroform.

Description and Physical Properties—White, glistening, silky needles or prisms. It is odorless, and has a very bitter taste.

One Gm. of Cinchonidine Sulphate is soluble in 65 cc. of water, 90 cc. of alcohol, and in 620 cc. of chloroform, at 25° C. One Gm. is soluble in 22 cc. of water at 80° C. and in 41 cc. of alcohol at 60° C. It is nearly insoluble in ether.

Tests for Identity—An aqueous solution of Cinchonidine Sulphate is lævorotatory.

The addition of ammonia T.S. to an aqueous solution of Cinchonidine Sulphate (1 in 100) produces a white precipitate of cinchonidine, which is but slightly soluble in ammonia T.S. or in ether. Sodium tartrate T.S. produces in an aqueous solution (1 in 100) a white precipitate of cinchonidine tartrate (*difference from cinchonine*).

An aqueous solution of Cinchonidine Sulphate yields with barium chloride T.S. a white precipitate, insoluble in hydrochloric acid.

Tests for Purity—A saturated aqueous solution of Cinchonidine Sulphate is neutral or faintly alkaline to litmus paper.

Dried to constant weight at 100° C., Cinchonidine Sulphate loses not more than 12 per cent (*water*).

Ash: not more than 0.1 per cent.

A solution of 0.1 Gm. of Cinchonidine Sulphate in 2 cc. of sulphuric acid is not darker than faint yellow (*readily carbonizable substances*).

A 10 cc. portion of a solution of the salt (1 in 1000) in diluted sulphuric acid exhibits only a faint, blue fluorescence (*quinine or quinidine*).

Macerate 0.5 Gm. of Cinchonidine Sulphate, with frequent agitation, at room temperature, with 20 cc. of distilled water, then add 0.5 Gm. of potassium and sodium tartrate, and continue the maceration with repeated agitation for one hour at 15° C., and filter the mixture. The addition of 1 drop of ammonia T.S. to the filtrate produces not more than a slight turbidity (*cinchonine or quinidine sulphate*).

Preserve in well-closed containers, protected from light.

N.F. Preparations—Elixir Cinchonæ Alkaloidorum and in other elixirs containing cinchona alkaloids in combination with iron, bismuth, etc.

Uses—This salt closely resembles quinine sulphate in its medicinal effects, and may be used for the same purposes but in somewhat larger doses. Dose, 2½ grains (0.15 Gm.).

CINCHOPHENUM. U.S. Cinchophen

[**Cinchophen.**—Acidum Phenylcinchoninicum U.S.P. IX, Phenyl-Quinoline-carboxylic Acid]

Cinchophen, when dried to constant weight over sulphuric acid, contains not less than 99 per cent of $C_6H_5.C_9H_5N.COOH = 249.18$.

Preparation—It may be prepared by heating a mixture of one molecule each of pyroracemic acid, benzaldehyde, and aniline in dehydrated alcohol.

Description and Physical Properties—Small, colorless, needle-like crystals, or a white to yellowish-white powder. It is odorless, has a slightly bitter taste, and is stable in the air.

Cinchophen is almost insoluble in cold water. One Gm. is soluble in about 400 cc. of chloroform, 100 cc. of ether, and in 120 cc. of alcohol, at 25° C. It is more readily soluble in hot than in cold alcohol.

Tests for Identity—Cinchophen melts at about 210° C. with partial decomposition.

A saturated solution of Cinchophen in hot diluted hydrochloric acid yields with platinic chloride T.S. a precipitate of yellowish-brown crystals.

Dissolve about 1 Gm. of Cinchophen in an excess of ammonia T.S., evaporate the solution to dryness on a water bath, or until free from the odor of ammonia, dilute to 20 cc. with distilled water, and filter: portions of the filtrate yield a white, flocculent precipitate with silver nitrate T.S., a yellowish, flocculent precipitate with lead acetate T.S., and a green, flocculent precipitate with copper sulphate T.S.

Tests for Purity—The ash from 0.2 Gm. is negligible.

A solution of 0.1 Gm. of Cinchophen in 5 cc. of sulphuric acid is not darker than yellow (*readily carbonizable substances*). On adding three drops of nitric acid to this solution, no reddish or brown color is produced.

Assay—Weigh accurately about 0.5 Gm. of Cinchophen, previously dried to constant weight over sulphuric acid, and dissolve it in 60 cc. of alcohol which has been neutralized with tenth-normal sodium hydroxide, using three drops of phenolphthalein T.S. as indicator, and warming gently to facilitate solution. Cool, and titrate the solution with tenth-normal sodium hydroxide until the pink color is restored. Each cc. of tenth-normal sodium hydroxide corresponds to 0.02492 Gm. of $C_6H_5.C_9H_5N.COOH$.

This assay is explained on page 1453.

Preserve in well-closed containers, protected from light.

Uses—This substance, commonly known as *atophan*, or phenylcinchoninic acid, is useful in acute gout; it relieves pain in this disease, acting more promptly than colchicum and without undesirable by-effects. In nonuratic joint affections, particularly acute articular rheumatism, favorable results are reported, while the chronic forms seem to yield to cinchophen only in isolated cases. It frequently relieves the pain of sciatica, but not invariably.

Dose—In gout the dose of cinchophen is from 8 grains (0.5 Gm.) four times a day to 15 grains (1 Gm.) three times a day suspended in large quantities of water. In order to prevent the precipitation of free uric acid from the urine with possibly resulting renal colic, it is necessary to administer simultaneously 225 grains (15 Gm.) of sodium bicarbonate in the course of the first day and from 75 to 150 grains (5 to 10 Gm.) on the following days. In articular rheumatism, Heller prescribes daily doses of from 45 to 75 grains (3 to 5 Gm.).

Unofficial Cinchophen Derivatives

Chloroxyl, N. N. R.—Phenylcinchoninic acid hydrochloride, $C_6H_5C_9H_5NCOOH.HCl$. The hydrochloride of 2-phenylquinolin-4-carboxylic acid.

Chloroxyl is a yellow crystalline powder with an astringent, slightly bitter taste. It is insoluble in water, ether or chloroform, but slightly soluble in alcohol.

Uses—The same as those of cinchophen.

Manufactured by Eli Lilly and Company.

Neocinchophen, N. N. R.—*Neocinchophenum.*—Ethyl-6-methyl-2-phenylquinolin-4-carboxylate, the ethyl ester of methyl-phenyl-quinolin-carboxylic acid.—$CH_3C_9H_4N.C_6H_5COOC_2H_5$, 6 : 2 : 4. Neocinchophen was first introduced as *novatophan*.

Uses and Doses—The same as those of cinchophen. It is practically tasteless.

Manufactured by The Abbott Laboratories.

NUX VOMICA. U. S. Nux Vomica

[Nux Vom.—Strychni Semen P. I.]

Nux Vomica is the dried ripe seed of *Strychnos Nux Vomica* Linné (Fam. *Loganiaceæ*).

Nux Vomica yields not less than 2.5 per cent of the alkaloids of Nux Vomica.

Description and Physical Properties—*Unground Nux Vomica*—Seed orbicular, nearly flat, occasionally somewhat bent, from 10 to 30 mm. in diameter, and from 4 to 5 mm. in thickness; externally grayish or greenish-gray, covered with appressed hairs, giving it a silky luster; hilum indicated by a circular scar at the center of one of the flattened sides, and connected with the micropyle by a ridge; very hard when dry; internally showing a thin and hairy seed-coat and a large grayish-white endosperm at one end of which is embedded a small embryo with two broadly ovate, 5- to 7-nerved cotyledons; inodorous; taste intensely and persistently bitter.

For further description see the U. S. P. X.

Assay—Place 10 Gm. of Nux Vomica, in fine powder, in a 250 cc. flask, add 100 cc. of ether-chloroform mixture, and proceed by Type Process A. Decant 50 cc. of the ethereal solution to complete the assay, using chloroform as the immiscible solvent in shaking out the alkaline liquid, and determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.0364 Gm. of the total alkaloids of Nux Vomica.

This assay is explained on page 1498.

U. S. P. Preparations—Extractum Nucis Vomicæ; Tinctura Nucis Vomicæ.

N. F. Preparations—Elixir Phosphori et Nucis Vomicæ (from Tincture); Fluidextractum Nucis Vomicæ; Pilulæ Aloes et Podophylli Compositæ (from Extract); Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ (from Extract).

Nux Vomica contains *strychnine, brucine* ($C_{23}H_{26}O_4N_2$), probably *loganin, igasuric acid*, protein compounds, gum, fixed oil, sugar, etc. Of the total alkaloids from Nux Vomica, strychnine usually represents about one-third to one-half, most of the remainder being brucine. Strychnine is official in the N. F. and will be considered separately. Brucine is readily soluble in alcohol and in chloroform, but like strychnine it is only sparingly soluble in ether. It is colored bright red by nitric acid but this may be distinguished from the morphine reaction by adding stannous chloride, which changes the brucine reaction to a violet. Its solution acquires a rose-red coloration with chlorine water. Anhydrous brucine has a melting point of 178° C., and an $[a]_D$ −119° to 127° in chloroform. Igasurine, once thought to be a distinctive alkaloid, is now considered to be a mixture. The fixed oil is soluble in alcohol.

Uses—Nux Vomica is poisonous in large doses; in doses of one and one-half grains (0.1 Gm.) it is tonic.

STRYCHNINA. N. F. Strychnine

(U. S. P. IX)

[Strych.]

An alkaloid [$C_{21}H_{22}O_2N_2$ = 334.30] obtained from nux vomica, and also obtainable from other seeds of the *Loganiaceæ*.

This alkaloid was first discovered in Ignatia bean in 1818 by the French pharmacists, Pelletier and Caventou who gave it at that time the name which it still bears. They discovered *brucine* in 1819. It occurs in numerous plants belonging to the *Strychnos* species. In nux vomica seeds (*Strychnos Nux Vomica*) a little less than one half of the alkaloid is strychnine, while in ignatia beans (*Strychnos Ignatia*) about two-thirds is strychnine; each contains from 2 to 3 per cent of total alkaloids. Both brucine and strychnine are present in other portions of the plants. These species are mainly Asiatic, while a South American species furnishes the product Curare (see page 1533).

Strychnine, has a $[a]_D$ of −132.07°, in alcohol. It is distilled unchanged at 270° C. under 5 mm. pressure.

Preparation—Take of nux vomica, rasped, 48 oz. troy; lime, in fine powder, 6 oz. troy; hydrochloric acid, 3½ oz. troy; alcohol, diluted alcohol, diluted sulphuric acid, ammonia water, purified animal charcoal, water, each, a sufficient quantity. Macerate the nux vomica for twenty four hours in 16 pints of water, acidulated with one-third of the hydrochloric acid; then boil for two hours, and strain with expression through a strong muslin bag. Boil the

residue twice successively in the same quantity of acidulated water, each time straining as before. Mix the decoctions and evaporate to the consistence of thin syrup; then add the lime previously mixed with a pint of water, and boil for ten minutes, frequently stirring. Pour the whole into a double muslin bag, and, having thoroughly washed the precipitate, press, dry, and powder it. Treat the powder repeatedly with diluted alcohol, in order to remove the brucine, until the washings are but faintly reddened by nitric acid. Then boil it repeatedly with alcohol until deprived of its bitterness, mix the several tinctures, and distil off the alcohol by means of a water bath. Having washed the residue, mix it with a pint of water, and, applying a gentle heat, drop in enough diluted sulphuric acid to neutralize and dissolve the alkaloid. Then add purified animal charcoal, and, having boiled the mixture for a few minutes, filter, evaporate, and set aside to crystallize. Dissolve the crystals in water, and add sufficient ammonia water to precipitate the strychnine. Lastly, dry this on bibulous paper, and keep it in a well-stoppered bottle.

In this process strychnine hydrochloride and brucine hydrochloride are first formed. They are then removed from the exhausted drug by straining. The alkaloids are precipitated by lime, and the strychnine is dissolved out of the excess of lime with boiling alcohol (the brucine having been previously removed by treatment with diluted alcohol), the alcoholic solution is evaporated, and sulphuric acid added to dissolve the alkaloid; the solution is decolorized and evaporated to crystallize. The crystals of strychnine sulphate are dissolved and strychnine is precipitated by adding ammonia water.

Official Description—Strychnine occurs in colorless, transparent, prismatic crystals, or as a white crystalline powder; odorless; permanent in the air. *Great caution must be used in tasting it and then only in very dilute solutions* which are exceedingly bitter.

Solubility—One Gm. of Strychnine dissolves in 6420 cc. of water, 136 cc. of alcohol, 5 cc. of chloroform, and in 180 cc. of benzene at 25° C.; also in 3100 cc. of boiling water and 34 cc. of boiling alcohol: very slightly soluble in ether.

Tests for Identity and Purity—Its saturated solutions are alkaline to litmus and are lævorotatory. Sulphuric acid containing 1 per cent of ammonium vanadate produces with Strychnine a deep violet-blue color, changing to a deep purple, and finally to a cherry-red.

A solution of about 0.1 Gm. of Strychnine in 2 cc. of sulphuric acid is not more than pale yellow (*readily carbonizable organic impurities*), but on adding a fragment of potassium dichromate, a deep blue color is momentarily produced, changing to deep violet, then to purplish-red, cherry-red, and finally to orange or yellow. Incinerate about 1 Gm. of Strychnine: not more than 0.1 per cent of ash remains.

Brucine—One cc. of a mixture of equal volumes of nitric acid and distilled water, added to about 0.1 Gm. of Strychnine, may produce a yellow, but not a red or reddish color.

N. F. Preparations—Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ; Elixir Pepsini, Bismuthi et Strychninæ; Liquor Hypophosphitum Compositus; Pilulæ Aloini, Strychninæ et Belladonnæ; Pilulæ Aloini, Strychninæ et Belladonnæ Compositæ; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Fortiores; Pilulæ Ferri, Quininæ, Strychninæ et Arseni Mites; Pilulæ Laxativæ Compositæ; Syrupus Ferri, Quininæ et Strychninæ Phosphatum; Syrupus Hypophosphitum Compositus.

Uses—Strychnine is a cardiac and nerve stimulant, and is given in doses of one-fortieth of a grain (0.0015 Gm.). It may sometimes be given in doses of one-twentieth of a grain (0.003 Gm.).

STRYCHNINÆ NITRAS. U.S. Strychnine Nitrate

[Strych. Nit.]

The nitrate [$C_{21}H_{22}O_2N_2.HNO_3 = 397.31$] of an alkaloid obtained chiefly from nux vomica.

Preparation—Strychnine Nitrate may be made by dissolving strychnine in warm diluted nitric acid, evaporating, and crystallizing.

Description and Physical Properties—Colorless, glistening needles or a white, crystalline powder. It is odorless and is stable in the air.

Caution—Strychnine Nitrate is extremely poisonous.

One Gm. of Strychnine Nitrate is soluble in 45 cc. of water, 150 cc. of alcohol, 50 cc. of glycerin, and in 105 cc. of chloroform, at 25° C. One Gm. is soluble in 10 cc. of boiling water and in 80 cc. of alcohol at 60° C. It is insoluble in ether.

Tests for Identity—An aqueous solution of Strychnine Nitrate is lævorotatory.

Dissolve about 0.05 Gm. of Strychnine Nitrate in 5 cc. of distilled water, add a few drops of ammonia T.S., and extract the liberated strychnine with 5 cc. of chloroform. Evaporate the chloroform to dryness on a water bath, cool, dissolve the residue in 2 cc. of sulphuric acid and add a fragment of potassium dichromate. On gently agitating the mixture, a blue color is momentarily produced, changing to violet, then to purplish-red, and finally to orange or yellow.

An aqueous solution of the salt, when superimposed in a test tube, upon diphenylamine T.S., develops a blue color at the zone of contact.

Strychnine Nitrate, heated with hydrochloric acid, produces a bright red color.

Tests for Purity—A solution of 0.5 Gm. of Strychnine Nitrate in 25 cc. of distilled water requires not more than 0.5 cc. of fiftieth-normal sodium hydroxide for neutralization, using one drop of methyl red T.S. as indicator.

Ash: not more than 0.1 per cent.

A solution of 0.1 Gm. of Strychnine Nitrate in 5 cc. of sulphuric acid is not darker than pale yellow (*readily carbonizable substances*).

The addition of 5 drops of silver nitrate T.S. to 20 cc. of an aqueous solution of Strychnine Nitrate (1 in 100), acidulated with 2 drops of diluted nitric acid, does not produce an opalescence at once (*chloride*), and no immediate turbidity is produced in 20 cc. of a similar solution by the addition of 5 drops of barium nitrate T.S. (*sulphate*).

One cc. of a mixture of equal volumes of nitric acid and distilled water, added to about 0.1 Gm. of Strychnine Nitrate, may produce a yellow, but not a red or reddish color (*brucine*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Glycerophosphatum Compositum; Syrupus Phosphatum cum Quinina et Strychnina.

Uses—Strychnine nitrate is a cardiac and nerve stimulant, and is given in the dose of one-thirtieth of a grain (0.002 Gm.).

STRYCHNINÆ SULPHAS. U. S. Strychnine Sulphate [Strych. Sulph.]

The sulphate $[(C_{21}H_{22}O_2N_2)_2.H_2SO_4.5H_2O = 856.75]$ of an alkaloid obtained chiefly from nux vomica.

Preparation—This salt is prepared during the process of making strychnine. (See Strychnina.)

Description and Physical Properties—Colorless or white crystals, or a white, crystalline powder. It is odorless and is efflorescent in dry air.

Caution—Strychnine Sulphate is extremely poisonous.

One Gm. of Strychnine Sulphate is soluble in 35 cc. of water, in 81 cc. of alcohol, and in 220 cc. of chloroform, at 25° C. One Gm. is soluble in 7 cc. of boiling water and in 26 cc. of alcohol at 60° C. It is freely soluble in glycerin but insoluble in ether.

Tests for Identity—An aqueous solution of Strychnine Sulphate is lævorotatory.

Add a fragment of potassium dichromate to a solution of 0.1 Gm. of Strychnine Sulphate in 2 cc. of sulphuric acid. A deep blue color is momentarily produced, changing to deep violet, then to purplish red, cherry-red, and finally to orange or yellow.

Sulphuric acid containing 1 per cent of ammonium vanadate produces with Strychnine Sulphate a deep violet-blue color, changing to a deep purple and finally to a cherry-red.

Barium chloride T.S. produces in an aqueous solution of the salt (1 in 50) a white precipitate, insoluble in hydrochloric acid.

Tests for Purity—A solution of 0.5 Gm. of Strychnine Sulphate in 20 cc. of distilled water requires not more than 0.5 cc. of fiftieth-normal sodium hydroxide for neutralization, using one drop of methyl red T.S. as indicator.

Dried to constant weight at 100° C., Strychnine Sulphate loses not more than 11 per cent.

Ash: not more than 0.1 per cent.

A solution of 0.1 Gm. of Strychnine Sulphate in 2 cc. of sulphuric acid is not darker than pale yellow (*readily carbonizable substances*).

One cc. of a mixture of equal volumes of nitric acid and distilled water, added to about 0.1 Gm. of Strychnine Sulphate, may produce a yellow, but not a red or reddish color (*brucine*).

Preserve in well-closed containers, protected from light.

N. F. Preparations—Elixir Cinchonæ Alkaloidorum, Ferri, Bismuthi et Strychninæ; Elixir Ferri, Quininæ et Strychninæ.

Uses—Strychnine sulphate is more useful, medicinally, than strychnine, only because it is much more soluble. The dose is one-thirtieth of a grain (0.002 Gm.).

Unofficial Strychnine Alkaloids and Preparations

STRYCHNINÆ GLYCEROPHOSPHAS

[Strychnine Glycerophosphate (N. F. IV)]

The glycerophosphate $[(C_{21}H_{22}O_2N_2)_2PO_4H_2(C_3H_7O_2).6H_2O]$ of the alkaloid strychnine.

White, rhombic crystals or as a white powder. Soluble in about 350 parts of water, also in about 310 parts of alcohol.

STRYCHNINÆ VALERAS

[Strychnine Valerate (N. F. IV)]

The valerate $[C_{21}H_{22}O_2N_2.HC_5H_9O_2]$ of the alkaloid strychnine.

A white, crystalline powder. Sparingly soluble in water, becoming less soluble on keeping, through the loss of valeric acid.

LIQUOR STRYCHNINÆ ACETATIS

[Solution of Strychnine Acetate (N. F. IV)—Hall's Solution of Strychnine]

	Metric	Alternative
Strychnine	**0.178 Gm**	3 gr.
Diluted Acetic Acid	**3.500 cc.**	67 min.
Alcohol	**25.000 cc.**	1 fl. oz.
Compound Tincture of Cardamom	**1.000 cc.**	19 min.
Distilled Water, a sufficient quantity, To make	**100 cc.**	4 fl. oz.

Dissolve the strychnine in the diluted acetic acid, add about 50 cc. [2 fl. oz.] of distilled water, then the alcohol, compound tincture of cardamom, and sufficient distilled water to make the product measure 100 cc. [4 fl. oz.] and filter. Dose, ten minims (0.6 cc.).

ERGOTA. U. S. Ergot

[Ergot.—Ergot of Rye, Secale Cornutum P. I., Spurred Rye]

Ergot is the dried sclerotium of *Claviceps purpurea* (Fries) Tulasne (Fam. *Hypocreaceæ*), developed on rye plants.

Ergot, in the form of the fluidextract, administered by intramuscular injection to single-comb, white Leghorn cocks, in doses not exceeding 0.5 cc. for each kilogram of body weight of cock, produces a darkening of the comb, corresponding in intensity to that caused by the same dose of a standard fluidextract of ergot, prepared as directed below. It contains not more than 5 per cent of seeds, fruits, or other foreign organic matter.

Ergot should be dried at a low temperature. It deteriorates with age and should not be kept longer than one year.

Description—Cylindraceous, obscurely 3-angled, tapering towards both ends, obtuse, somewhat curved, from 1 to 4.5 cm. in length and from 3 to 5 mm. thick, longitudinally furrowed; externally dark purple or dark reddish-brown; fracture short; internally white, tinged with purple or gray; odor characteristic but free from mustiness or rancidity; taste oily, somewhat acrid, disagreeable.

For further description see the U. S. P. X.

Test for Purity—When crushed or powdered, Ergot does not develop a rancid or ammoniacal odor upon the addition of hot water.

Assay—This drug is assayed biologically. The details of the official method will be found on page 1508.

U. S. P. Preparation—Fluidextractum Ergotæ.

N. F. Preparation—Extractum Ergotæ Aquosum.

Ergot preparations rapidly deteriorate, especially during the first few months after manufacture, hence the requirement that the "standard fluidextract" should be aged for six months before adjusting its activity.

Although the Pharmacopœia does not specifically require the aging of the fluidextract before standardizing, in practice, it becomes a necessity as a fresh product, though standardized, would soon fall below the official requirement for activity.

Experience has demonstrated that Ergot and its preparations retain their activity much longer if stored in vacuum containers.

The following abstract from the N. N. R. discussion of the active principles of Ergot sets forth the present day knowledge:

It has been shown that ergot contains at least two alkaloids and a series of active amines. The numerous names applied to these principles and to impure mixtures render the literature confusing. The chief constituents are these:

Ergotoxine or *hydroergotinine*, $C_{35}H_{41}O_6N_5$, is an amorphous alkaloid occurring in alcoholic extracts. It is responsible for the characteristic action on the cock's comb, and is concerned in uterine and vascular effects. It is rather unstable and by loss of water changes into its lactone. *Ergotinine*, $C_{35}H_{39}O_5N_5$, is a crystalline alkaloid, with very weak actions.

Both of these alkaloids exist ready formed in ergot, but can be easily converted into each other by chemical means. Both are insoluble in water and petroleum benzin, sparingly soluble in ether, and readily soluble in almost all other organic solvents. Ergotoxine is easily soluble in cold alcohol; ergotinine is sparingly soluble.

Ergotoxine has a melting point of 162° C. and the specific rotation is variable; *ergotinine* melts at 229° C. and has an $[a]_D$ +338° in alcohol.

Para-hydroxyphenylethamine, $OH.C_6H_4.CH_2.CH_2.NH_2$. This is closely related to epinephrine in structure and action. It is mainly responsible for the pressor effect, and is not materially concerned in the uterine action.

Beta-iminazolylethylamine, *4-meta-aminoethylglyoxaline* $C_3H_3N_2.CH_2.CH_2.NH_2$. This amine lowers the blood pressure, and stimulates the excised uterus powerfully.

A number of other aromatic amines occur, such as *agmatine*, *guanidobutylamine* and *isoamylamine*. *Acetyl-choline* is frequently present, and lowers the blood pressure by a cardiac action.

Ergotine is a name applied to a variety of pharmaceutical extracts such as the aqueous extract of the N. F. They are generally prepared in such a way that they contain mainly the amines, and relatively little of the alkaloids.

It will be seen that several of the constituents exert uterine actions, and it is not yet known which of these is the most important in the effects of the crude drug. The galenic preparations must vary in composition according to the solvent. The alcoholic fluidextract probably owes its activity mainly to ergotoxine; the aqueous preparations, including the solid extracts and "ergotines", owe theirs probably to the amines, particularly to *histamine*. The isolated principles have not been used sufficiently to decide whether or not they can take the place of the natural mixture.

All ergot preparations, especially those containing water, deteriorate with age. It is, therefore, of advantage to standardize the ergot preparations, as is now required by the Pharmacopœia. Because of the complex composition, no satisfactory chemical assay has been devised. Different methods of bioassay have been proposed; but because of its varied physiologic activities it is not certain how perfectly these tests reflect the therapeutic efficiency of the drug; however, the cock's comb method of assay is, in general, considered to be satisfactory for the purpose and has been adopted by the U. S. P. X.

Uses—It is used as a parturient and hemostatic. Dose, thirty grains (2 Gm.). Sclerotic acid has been used in medicine in doses of one-half to three-fourths of a grain (0.03 to 0.048 Gm.).

Unofficial Ergot Preparations

Ergot Aseptic, N. N. R.—A liquid extract of ergot is standardized by the cock's comb method of assay so that 1 cc. represents 2 Gm. of ergot.

Uses—The same as those of ergot. Ergot aseptic is intended for intramuscular injection and is marketed in ampuls only. The date of manufacture appears on each package and the product is not guaranteed to possess its full potency for more than one year from time of manufacture. Dose, fifteen to thirty minims (1 to 2 cc.).

Manufactured by Parke, Davis and Company, Detroit.

Ergotinine Citrate, N. N. R.—*Ergotininæ Citras*—The citrate of ergotinine, a crystalline alkaloid, probably $C_{35}H_{39}O_5N_5$, derived from ergot. A grayish-white, amorphous powder, slowly soluble in water. It gives an acid reaction to litmus paper. One part of ergotinine dissolves at 18° C. in 292 parts of alcohol. It is insoluble in water.

Uses—According to the investigations of Barger and Dale, ergotinine has very slight physiologic activity when it enters the system unchanged, but it is likely to be converted to a certain extent into ergotoxine which possesses marked physiologic activity and appears to represent the pharmacologic actions of ergot. The action of ergotinine, when given by mouth or when injected hypodermically, is variable in intensity but represents the action of ergot.

Used in the treatment of headaches and uterine hemorrhage.

Dose—$\frac{1}{200}$ to $\frac{1}{100}$ grain (0.00032 to 0.00064 Gm.).

Manufactured by Burroughs, Wellcome and Company, and F. Hoffmann-LaRoche and Company.

Ergotinine is obtained by extracting the residue left on evaporation of an a coholic tincture of ergot with light petroleum to remove oily matter, dissolving the residue in ethyl acetate and shaking with citric acid solution. Sodium bromide or hydrobromic acid is then added and the precipitated hydrobromides of the alkaloids, ergotinine and ergotoxine are collected. The mixed hydrobromides are dissolved in caustic soda and shaken with ether; in this way ergotinine is removed first. Finally, the ergotinine is crystallized from alcohol, leaving ergotoxine and impurities in the mother liquor. By interaction of ergotinine with citric acid, ergotinine citrate is obtained.

Ergotole, N. N. R.—*Extractum Ergotæ Liquidum*—A liquid extract of ergot containing 19 per cent of alcohol. It is standardized on the uterus of the virgin guinea-pig so that a 1 : 2500 dilution of ergotole has the same activity as a 1 : 20,000,000 dilution of beta-iminazolylethylamine hydrochloride.

Ergotole is a brownish red liquid having the odor and taste of ergot.

Uses—The same as those of ergot.

Dose—Orally, from 15 to 60 minims (1 to 4 cc.); hypodermically, from 5 to 20 minims (0.3 to 1.2 cc.).

Manufactured by Sharp and Dohme, Baltimore.

Extract of Ergot, Purified, N. N. R.—*Extractum Ergotæ Purificatum.—Ergotin Bonjean.—Extractum Secalis Cornuti.—Extractum Ergoti.*—An aqueous extract of ergot purified by alcohol, corresponding to the aqueous extract of the N. F. (see page 465).

Actions and Uses—The same as those of ergot.

Dose—From 3 to 8 grains (0.2 to 0.5 Gm.).

This preparation should not be confused with these:

Ergotin Wernich (Pure Dried), a purified and dialyzed dried aqueous extract of ergot.

Ergotin Wernich (Liquid), a dialyzed extract of ergot, in the form of a reddish-brown liquid.

Ergotin Wernich (Soft), a purified and dialyzed soft extract of ergot; a reddish-brown syrupy liquid.

Ergotin Wiggers (Pure Dried), a dried, alcohol-purified extract of ergot.

Ergotin Yvon, a fluidextract of ergot prepared by extracting with dilute solution of tartaric acid.

Ergotin-Merck, N. N. R.—A brand of extract of ergot, purified.

Distributed by Merck and Company.

Liquor Ergot-Mulford N. N. R.—*Cornutol.*—A biologically tested liquid extract of ergot, containing the water-soluble constituents of ergot and about 10 per cent of alcohol.

It is a brownish-red liquid, having a characteristic, not unpleasant, odor and disagreeable taste.

Uses—The same as those of ergot.

Dose—Hypodermically, from 10 to 30 minims (0.6 to 2 cc.); by the mouth, from 10 to 60 minims (0.6 to 4 cc.) repeated as often as may be necessary. On account of the deterioration liable to occur in this preparation, the date when it was tested appears on each package. The air has been removed from the vacules before sealing to prevent deterioration.

Manufactured by H. K. Mulford Company, Philadelphia.

Secacornin, N. N. R.—*Ergotin-Roche.*—A solution of the active principles of ergot in a menstruum consisting of distilled water, glycerin and 7.5 per cent of alcohol. One cubic centimeter of secacornin corresponds to 4 Gm. of ergot, U. S. P., and is said to be standardized according to the method of Kehrer.

Secacornin is a dark brown solution, said to be sterile. It is claimed that it does not deteriorate on keeping.

Uses—The same as those of ergot.

Dose—8 minims (five-tenths cc.) is equivalent to 30 minims (2 cc.) of fluidextract of ergot, U. S. P. It may be given by intramuscular injection in doses of from 8 to 15 minims (0.5 to 1 cc.).

Manufactured by F. Hoffmann-LaRoche and Company.

Tyramine Hydrochloride, N. N. R.—See Epinephrine, page 1195.

PHYSOSTIGMA. (U. S. P. IX) Physostigma

[Calabar Bean, Ordeal Bean]

The dried ripe seeds of *Physostigma venenosum* Balfour (Fam. *Leguminosæ*), yielding not less than 0.15 per cent of the alkaloids of Physostigma.

Physostigmine ($C_{15}H_{21}O_2N_3$) (or *eserine*) is the most important constituent. Several other alkaloids are also present, mainly *eseridine, eseramine* and *geneserine.*

The melting point of *physostigmine* varies according to the form of crystal. One, a stable form, melts at 105° C., another form melts at 86° C. Solutions of the alkaloid are strongly alkaline and will precipitate ferric hydroxide from a solution of ferric chloride. It has an $[\alpha]_D$ of —75.8°, in chloroform. On exposure to air or in the presence of alkali the alkaloid oxidizes to *rubreserine* ($C_{13}H_{16}O_2N_2.H_2O$) which crystallizes from water in red needles.

Description—Oblong or ellipsoidal, somewhat compressed reniform, from 15 to 30 mm. in length and from 10 to 15 mm. in thickness; externally reddish or chocolate brown, smooth, somewhat wrinkled near the brownish-black groove, the latter being about 2 mm. in width and extending almost the entire length of the convex edge and in which are found frequently the remains of the white membranous funiculus, the margins of the seed-coat on both sides of the groove somewhat elevated, of a yellowish-red or brownish-red color and somewhat thickened; embryos large, white, with short hypocotyl and two concavo-convex cotyledons. Taste at first starchy, afterwards acrid.

Assay—Introduce 15 Gm. of Physostigma in No. 60 powder, into a flask of about 250 cc. capacity, and add 150 cc. of ether. Stopper the flask, shake it well and allow it to stand ten minutes, then add 10 cc. of an aqueous solution of sodium bicarbonate (1 in 20) and shake the mixture vigorously at intervals during four hours. Now add 15 cc. of distilled water, again shake the flask well, and, when the drug has settled, decant 100 cc. of the ether solution, representing 10 Gm. of Physostigma. Filter the solution through a pledget of purified cotton into a beaker and rinse the graduate and cotton with ether. Add 20 cc. of tenth-normal sulphuric acid and evaporate off the ether, stirring during the evaporation with a rubber-tipped glass rod. After the resinous and fatty matter has agglutinated, pour off the acid solution through a wetted filter into a separator. Redissolve the residue in the beaker in about 15 cc. of ether, add 2 cc. of tenth-normal sulphuric acid, evaporate off the ether with continued stirring as before and pour the acid solution on the filter. Repeat this operation until all of the alkaloid is extracted and then wash the filter with distilled water until it is free from alkaloids. Collect the solution and washings in a separator, add sufficient sodium bicarbonate to make the solution decidedly alkaline to litmus and completely extract the alkaloids by shaking it out repeatedly with ether. Wash the combined ether solutions with 10 cc. of distilled water, separate the water completely, and filter the ether solution, washing the container and filter with ether. Evaporate the ether solution to dryness, dissolve the alkaloids from the residue in exactly 5 cc. of tenth-normal sulphuric acid and titrate the excess of acid with fiftieth-normal potassium hydroxide, using cochineal T.S. as indicator.

Each cc. of tenth-normal sulphuric acid consumed corresponds to 27.52 milligrams of the alkaloids of Physostigma.

Uses.—This drug is no longer official as the alkaloid offers a more satisfactory therapeutic agent. The drug is sedative, and acts as a powerful poison, contracting the pupil of the eye. Dose, one to three grains (0.06 to 0.2 Gm.).

PHYSOSTIGMINÆ SALICYLAS. U.S. Physostigmine Salicylate

[Physostig. Salicyl.—Eserine Salicylate]

The salicylate [$C_{15}H_{21}O_2N_3.C_7H_6O_3 = 413.35$] of an alkaloid obtained from the dried ripe seed of *Physostigma venenosum* Balfour (Fam. *Leguminosæ*).

Preparation—This salt may be made by adding 2 parts of physostigmine to a solution of 1 part of salicylic acid in 35 parts of boiling distilled water, and allowing the salt to crystallize on cooling.

Description and Physical Properties—Colorless or faintly yellow, shining, odorless crystals. It acquires a red tint when long exposed to light and air.

Caution—Physostigmine Salicylate is extremely poisonous.

One Gm. of Physostigmine Salicylate is soluble in 75 cc. of water, 16 cc. of alcohol, 6 cc. of chloroform, and in 250 cc. of ether, at 25° C. One Gm. is soluble in 16 cc. of water at 80° C., and in 5 cc. of boiling alcohol.

Tests for Identity—A cold, saturated aqueous solution of Physostigmine Salicylate is neutral, or only faintly acid to litmus paper. Upon standing, the solution usually acquires a pink color.

Evaporate on a water bath about 0.005 Gm. of Physostigmine Salicylate with a few drops of ammonia T.S.: a blue residue is produced which, when dissolved in alcohol, yields a red, fluorescent solution upon the addition of an excess of acetic acid. On adding a few drops of sodium hydroxide T.S. to 5 cc. of a cold-saturated aqueous solution of the salt, a pink color rapidly develops.

Ferric chloride T.S. produces a deep violet color in an aqueous solution of Physostigmine Salicylate.

Tests for Purity—The ash from 0.1 Gm. is negligible.

A solution of 0.1 Gm. of Physostigmine Salicylate in 2 cc. of sulphuric acid does not become darker than yellow within five minutes (*readily carbonizable substances*).

Precipitate the salicylic acid from 10 cc. of a cold, saturated aqueous solution of the salt with a slight excess of diluted hydrochloric acid, and filter: the filtrate is not rendered turbid at once by the addition of 5 drops of barium chloride T.S. (*sulphate*).

Preserve in small, well-closed containers, protected from light.

Uses—The salts of physostigmine, or eserine, are used to contract the pupil of the eye. The advantage possessed by the salicylate is that it is more permanent and less liable to deliquesce. The addition of a few grains of boric acid to a solution of the salt is said to inhibit the formation of the red decomposition product which is produced by alkalies and which frequently occurs in solutions of physostigmine salts which have been dispensed upon prescriptions. A red or discolored solution should not be used. The dose for internal administration should not be more than one-thirtieth of a grain (0.002 Gm.).

Solanaceous Drugs

Belladonna, hyocyamus, and stramonium all yield alkaloids belonging to the solanaceous group. There are also many other plants of this group which are commercially valuable, being used largely in the manufacture of the various alkaloids.

The alkaloids of the most important plants and their distribution are as follows:

Plant	Part yielding alkaloid	Per cent of total alkaloid	Most important alkaloids
Atropa Belladonna	leaves	0.15–0.60	hyoscyamine
	root	0.10–0.70	hyoscyamine
	seeds	about 0.80	hyoscyamine
Datura Metel	leaves	0.25–0.55	hyoscine (scopolamine)
Datura Stramonium	leaves	0.20–0.45	hyoscyamine
	seeds	0.20–0.48	hyoscyamine
Hyoscyamus muticus	leaves	about 1.4	hyoscyamine
Hyoscyamus niger	leaves	0.045–0.080	hyoscyamine
	tops	0.070–0.100	hyoscine

It is said that atropine rarely occurs, as such, in any of the plants, but is always the product of the racemisation of the lævo-isomeride, hyoscyamine. Commercial atropine is therefore entirely obtained from plants rich in hyoscyamine and practically free from the other solanaceous alkaloids. The separated hyoscyamine is converted into atropine by the action of weak alkalies. Stramonium furnishes in this country a large amount of the hyoscyamine for the manufacture of atropine.

Scopolamine (*hyoscine*) is produced to a large extent from *Datura Metel* as well as from the mother liquors after crystallization of hyoscyamine.

Numerous other alkaloids of lesser importance are present in various members of the family, as *belladonnine*, *meteloidine*, and numerous synthetic alkaloids.

BELLADONNÆ FOLIA. U. S. Belladonna Leaves

[**Bellad. Fol.**—Deadly Nightshade Leaves, Belladonnæ Folium P. I.]

Belladonna Leaves consist of the dried leaves and tops of *Atropa Belladonna* Linné (Fam. *Solanaceæ*).

Belladonna Leaves yield not less than 0.3 per cent of the alkaloids of Belladonna Leaves, and contain not more than 3 per cent of their stems over 10 mm. in diameter, and yield not more than 3 per cent of acid-insoluble ash.

Description—Usually matted together, crumpled or broken; leaves mostly light green, from 5 to 20 cm. in length, and from 4 to 12 cm. in width, broadly ovate, apex acute, margin entire, narrowed into the petiole, with few hairs, the latter more abundant along the veins, and numerous whitish dots (crystal cells) visible with a lens; stems more or less hollow and flattened, finely hairy when young; flowers with campanulate corolla, yellowish-purple, becoming faded, usually subtended by the calyx; fruits nearly globular, green to brown or purplish-black with numerous, flattened somewhat reniform seeds, up to 2 mm. in width; odor slight, somewhat tobacco-like when moistened; taste somewhat bitter and acrid.

For further description see the U. S. P. X.

Assay—Proceed by Type Process B, using 10 Gm. of Belladonna Leaves in fine powder, ether-chloroform mixture for percolating the drug, and chloroform as the immiscible solvent for extracting the alkaloid from the aqueous liquid. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of Belladonna Leaves.

This assay is explained on page 1496.

U. S. P. Preparations—Emplastrum Belladonnæ (from Extract); Extractum Belladonnæ (Pilular and Powdered); Fluidextractum Belladonnæ Foliorum; Tinctura Belladonnæ; Unguentum Belladonnæ (from Pilular Extract).

N. F. Preparations—Pilulæ Aloes et Podophylli Compositæ (from Pilular Extract); Pilulæ Aloini Compositæ (from Pilular Extract); Pilulæ Aloini, Strychninæ et Belladonnæ (from Pilular Extract); Pilulæ Aloini, Strychninæ et Belladonnæ Compositæ (from Pilular Extract); Pilulæ Laxativæ Compositæ (from Pilular Extract).

BELLADONNÆ RADIX. U. S. Belladonna Root

[**Bellad. Rad.**—Deadly Nightshade Root]

Belladonna Root is the dried root of *Atropa Belladonna* Linné (Fam. *Solanaceæ*).

Belladonna Root yields not less than 0.45 per cent of the alkaloids of Belladonna Root, and contains not more than 10 per cent of its stem bases and woody crowns, and not more than 2 per cent of other foreign organic matter, and yields not more than 4 per cent of acid-insoluble ash.

Description and Physical Properties—*Unground Belladonna Root*—Cylindrical or tapering, sparingly branched, often split longitudinally or broken transversely; from 0.5 to 4 cm. in thickness; light grayish-brown externally, nearly white internally; somewhat wrinkled longitudinally and the soft periderm frequently abraded; fracture short, mealy and emitting a puff of dust consisting chiefly of starch grains; nearly odorless when dry, but characteristic when moistened; taste sweetish, then bitterish and acrid.

For further description see the U. S. P. X.

Assay—Proceed by Type Process B, using 10 Gm. of Belladonna Root in fine powder, ether-chloroform mixture for percolating the drug, and chloroform as the immiscible solvent for extracting the alkaloids from the aqueous liquid. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of Belladonna Root
This assay is explained on page 1497.

U. S. P. Preparation—Fluidextractum Belladonnæ Radicis.
N. F. Preparation—Linimentum Belladonnæ (from Fluidextract).

Uses—Belladonna is narcotic and poisonous. It dilates the pupil of the eye. Dose, three-fourths to two grains (0.045 to 0.125 Gm.).

ATROPINA. U. S. Atropine

[Atrop.]

An alkaloid [$C_{17}H_{23}O_3N$ = 289.28] chiefly obtained from belladonna.

Atropine was discovered by Mein, a German pharmacist, in 1833, simultaneously with its preparation by Geiger and Hess, two German chemists.

It sublimes unchanged when heated rapidly, and is optically inactive if pure. It exerts its mydriatic effect in a dilution of 1 in 130,000, when applied to the eye of a cat.

Preparation—This alkaloid may be prepared by adding sulphuric acid to a concentrated alcoholic tincture of the root to convert the atropine into the sulphate, distilling off the alcohol, adding water to the residuary liquid, filtering to separate oil and resin, and treating the filtrate with potassium hydroxide and chloroform. By separating and evaporating the latter, atropine is obtained. This is purified by redissolving the crystals and filtering the solution, decolorizing with animal charcoal and recrystallization.

Description and Physical Properties—White, odorless crystals.
Caution—Atropine is extremely poisonous.

One Gm. of Atropine is soluble in 455 cc. of water, 2 cc. of alcohol, about 27 cc. of glycerin, 1 cc. of chloroform, and in 25 cc. of ether, at 25° C. One Gm. is soluble in 90 cc. of water at 80° C., and in 1.2 cc. of alcohol at 60° C.

Tests for Identity—Atropine melts between 114° and 116° C.

Atropine is optically inactive.

Its saturated aqueous solution is alkaline to litmus paper and to phenolphthalein T.S.

Add a few drops of nitric acid to about 0.01 Gm. of Atropine contained in a porcelain dish, and evaporate the mixture to dryness on a water bath: a yellow residue is obtained. Add to the cooled residue a few drops of alcoholic potassium hydroxide T.S. and a fragment of potassium hydroxide: an intensely violet color is produced. (*Hyoscyamine* and *hyoscine* produce the same color as Atropine, but the presence of *other alkaloids* masks the reaction.)

Gold chloride T.S. produces in a solution of Atropine (1 in 50) in diluted hydrochloric acid, a lusterless precipitate. (*Hyoscyamine* yields a lustrous precipitate.)

Tests for Purity—Five cc. portions of a solution made by dissolving 0.2 Gm. of Atropine in 1 cc. of normal sulphuric acid and 14 cc. of distilled water, do not respond to the platinic chloride test for *most other alkaloids* or the test for *apoatropine* or *belladonnine* described under *Atropinæ Sulphas*. Atropine complies with the tests for *ash* and *readily carbonizable substances* under *Atropinæ Sulphas*.

Uses—Atropine is chiefly used to dilate the pupil of the eye. It is employed preferably as a solution in sterile olive oil or in an ointment vehicle. The sulphate, however, is preferred on account of its greater solubility in water. It has the properties of belladonna when given internally, and is narcotic. Dose, one one-hundred-and-sixtieth to one-sixtieth of a grain (0.0004 to 0.001 Gm.).

ATROPINÆ SULPHAS. U. S. Atropine Sulphate

[Atrop. Sulph.]

The sulphate [$(C_{17}H_{23}O_3N)_2H_2SO_4H_2O$ = 694.65] of the alkaloid atropine.

Preparation—Atropine sulphate may be prepared by suspending 120 grains of atropine in 4 fl. dr. of distilled water and adding very dilute sulphuric acid

until the alkaloid is dissolved and the solution is neutral. The latter is then evaporated to dryness at a temperature not exceeding 37.7° C. (100° F.).

Description and Physical Properties—A white, odorless, crystalline powder. It is efflorescent in dry air.

Caution—Atropine Sulphate is extremely poisonous.

One Gm. of Atropine Sulphate is soluble in 0.4 cc. of water, 5 cc. of alcohol, 2.5 cc. of glycerin, 420 cc. of chloroform, and in 3000 cc. of ether, at 25° C. One Gm. is soluble in 2.5 cc. of boiling alcohol.

Tests for Identity—Melting point: not below 188° C.

Add a few drops of nitric acid to about 0.01 Gm. of Atropine Sulphate, contained in a porcelain dish, and evaporate the mixture to dryness on a water bath: a yellow residue is obtained. Add to the cooled residue a few drops of alcoholic potassium hydroxide T.S. and a fragment of potassium hydroxide: an intensely violet color is produced. (*Hyoscyamine* and *hyoscine* produce the same color as Atropine, but the presence of *other alkaloids* masks the reaction.)

Gold chloride T.S. produces in an aqueous solution of Atropine Sulphate (1 in 50) a lusterless precipitate. (*Hyoscyamine* yields a lustrous precipitate.)

Barium chloride T.S. produces in an aqueous solution of Atropine Sulphate a white precipitate which is insoluble in hydrochloric acid.

Tests for Purity—An aqueous solution of Atropine Sulphate (1 in 20) is neutral to litmus paper.

The ash from 0.1 Gm. is negligible.

One-tenth Gm. of Atropine Sulphate dissolves in 2 cc. of concentrated sulphuric acid without producing more than a slightly yellow coloration (*readily carbonizable substances*), and the solution becomes only light yellow upon the addition of 0.1 cc. of nitric acid (*many other alkaloids*).

In an aqueous solution of Atropine Sulphate (1 in 50), mixed with a few drops of hydrochloric acid, platinic chloride T.S. produces no precipitate (*most other alkaloids*).

An aqueous solution of the salt (1 in 60) is rendered turbid by sodium hydroxide, but no turbidity is produced immediately upon the addition of 2 cc. of ammonia T.S. to 5 cc. of the solution (*apoatropine* or *belladonnine*).

Uses—Atropine sulphate is preferred to the alkaloid for use as a mydriatic. An aqueous solution is generally employed for this purpose. The internal dose is from one one-hundred-and-sixtieth to one-sixtieth of a grain (0.0004 to 0.001 Gm.).

Unofficial Atropine Derivatives

SYNTHETIC MYDRIATICS

The usefulness of atropine is somewhat diminished by the fact that it affects, simultaneously, so many organs; on the eye its effects continue much longer than is, in many cases, desirable. Many attempts have been made to secure drugs of the atropine type with more specific actions or such as have a more transitory effect upon the eye. One of these drugs (homatropine) is a synthetic alkaloid analogous to atropine, the only difference being that it contains mandelic acid instead of tropic acid in combination with tropine; eucatropine is a combination of mandelic acid and a base similar to that contained in beta-eucaine.

Eucatropine, N. N. R.—Euphthalmine.—Phenyl-glycolyl-methyl-vinyl-diacetonalkamine Hydrochloride.—C_5H_6N-$(CH_3)_4(C_6H_5CHOH.COO)HCl$ = the 1,2,6,6-tetra-methyl-4-mandeloxy-piperidine hydrochloride. Eucatropine was first introduced as euphthalmine.

A white, granular, odorless powder; permanent in the air. It is very soluble in water; freely soluble in alcohol and chloroform; insoluble in ether.

Uses—Eucatropine produces prompt mydriasis free from anesthetic action, pain, corneal irritation, or increase in intra-ocular tension. It has little or no effect on accommodation, and such effect as it has disappears more rapidly than with atropine, cocaine, homatropine, etc. It is useful as an aid in ophthalmoscopic examinations in place of atropine, homatropine, etc.

Dose—From 2 to 3 drops of from a 5 to a 10 per cent solution, according to the age of the patient and the nature of the case, are instilled into the eye.

Manufactured by the Werner Drug and Chemical Company.

Homatropine Hydrochloride, N. N. R.—Homatropinæ Hydrochloridum.—$C_{16}H_{21}O_3NHCl$.—The hydrochloride of the alkaloid homatropine, obtained by the condensation of tropine and mandelic acid.

Small white crystals, soluble in water and alcohol.

Uses—Homatropine hydrochloride is given for the same indications as the hydrobromide.

Dose—It is applied to the eye in 1 per cent solution.

HOMATROPINÆ HYDROBROMIDUM. U.S. Homatropine Hydrobromide

[**Homatrop. Hydrobr.**—Homatropine Bromide]

The hydrobromide [$C_{16}H_{21}O_3N.HBr$ = 356.18] of homatropine, an alkaloid obtained by the condensation of tropine and mandelic acid. Preserve it in well-closed containers, protected from light.

Preparation—It is made by heating *tropine*, $C_8H_{15}ON$, with *mandelic (phenyl glycolic) acid*, in the presence of hydrochloric acid; ammonia is added, and the homatropine which is liberated is dissolved out by chloroform; the solution is evaporated, hydrobromic acid added, and the crystals of Homatropine Hydrobromide purified by recrystallization.

Description and Physical Properties—White crystals or a white, crystalline powder. It is odorless.

Caution—Homatropine Hydrobromide is extremely poisonous.

One Gm. of Homatropine Hydrobromide is soluble in 6 cc. of water, 40 cc. of alcohol, and in 420 cc. of chloroform, at 25° C. One Gm. is soluble in 12 cc. of alcohol at 60° C. It is insoluble in ether.

Tests for Identity—It melts at about 212° C. with partial decomposition.

Iodine T.S. produces in an aqueous solution of Homatropine Hydrobromide a brown precipitate; silver nitrate T.S. produces a yellowish-white precipitate, insoluble in nitric acid.

Shake 2 cc. of chloroform with 1 cc. of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine T.S. have been added: the chloroform acquires a brownish color.

Add a slight excess of ammonia T.S. to 1 cc. of an aqueous solution of the salt (1 in 100), shake it with chloroform, and evaporate the chloroform solution to dryness on a water bath: the residue becomes yellow and finally brick-red when warmed with about 1.5 cc. of a solution made by dissolving 1 Gm. of mercuric chloride in 50 cc. of a mixture of 5 volumes of alcohol and 3 volumes of distilled water (*difference from most other alkaloids except atropine and hyoscyamine*).

Tests for Purity—Its aqueous solution (1 in 20) is neutral to litmus paper.

The ash from 0.1 Gm. is negligible.

One cc. of an aqueous solution of the salt (1 in 20) is not precipitated by tannic acid T.S. Another 1 cc. portion acidulated with hydrochloric acid yields no precipitate with platinic chloride T.S. (*difference from most other alkaloids*).

Add 5 drops of nitric acid to about 0.01 Gm. of Homatropine Hydrobromide, and evaporate to dryness in a porcelain dish on a water bath: the residue does not become violet on the addition of a few drops of alcoholic potassium hydroxide T.S. (*atropine, hyoscyamine, or scopolamine*).

Uses—Homatropine Hydrobromide is usually preferred to atropine as a mydriatic, because it is less toxic, and the effects subside far more rapidly. Dose, one one-hundred-and-twentieth of a grain (0.0005 Gm.).

SCOPOLAMINÆ HYDROBROMIDUM. U. S. Scopolamine Hydrobromide

[Scopolamin. Hydrobrom.—Hyoscine Hydrobromide, Scopolamine Bromide]

The hydrobromide [$C_{17}H_{21}O_4N.HBr.3H_2O$ = 438.24] of lævorotatory scopolamine, also known as hyoscine, obtained from various plants of the *Solanaceæ*. Preserve it in well-closed containers, protected from light.

Preparation—It is produced largely from the mother liquors remaining after the crystallization of hyoscyamine. It has an $[a]_D$ of $-18°$, in alcohol.

The U. S. P. scopolamine (or hyoscine) consists of the lævorotatory compound. The optically inactive compound has the same effect on the central nervous system as has the official or lævorotatory compound; it has but one-half the activity on peripheral organs (eye, heart, secreting glands). The absence of the latter action may in some cases be desirable, and in such cases there may be advantages in using the optically inactive compound; this has been introduced under the name "euscopol".

Description and Physical Properties—Colorless, transparent, rhombic crystals, sometimes of large size. It is odorless, and slightly efflorescent.

Caution—Scopolamine Hydrobromide is extremely poisonous.

One Gm. of Scopolamine Hydrobromide is soluble in 1.5 cc. of water and in 20 cc. of alcohol, at 25° C. It is slightly soluble in chloroform, but insoluble in ether.

Tests for Identity and Purity—(See the U. S. P. X.).

Preserve in well-closed containers, protected from light.

Uses—Scopolamine Hydrobromide is a powerful mydriatic and cerebral and spinal sedative. It is also known as *hyoscine hydrobromide*, and this title was recognized in the U. S. P. VIII in a separate article. Dose, one one-hundred-and-twentieth grain (0.0005 Gm.).

Unofficial Preparation of Scopolamine

Scopolamine Stable-Roche, N. N. R.—*Scopomannit*—An aqueous solution of pure scopolamine hydrobromide, protected against decomposition by the addition of 10 per cent of mannite, supplied in ampuls, each containing 1.2 cc. (1 cc. contains 0.0003 Gm. of scopolamine hydrobromide).

Uses and Dose—The same as those of scopolamine hydrobromide, U. S. P.

Manufactured by F. Hoffmann-LaRoche and Company.

HYOSCYAMUS. U. S. Hyoscyamus

[Hyosc.—Henbane, Hyoscyami Folium P. I.]

Hyoscyamus is the dried leaf, with or without the tops, of *Hyoscyamus niger* Linné (Fam. *Solanaceæ*).

Hyoscyamus yields not less than 0.065 per cent of the alkaloids of Hyoscyamus and contains not more than 25 per cent of its stems, none of which is more than 7 mm. in thickness. It yields not more than 12 per cent of acid-insoluble ash.

Description—Usually much wrinkled, matted and broken, frequently consisting of leaves, stems, and flowering and fruiting tops. Leaves ovate or ovate-lanceolate, inequilateral, with petioles up to one-third the length of the blade, or sessile; apex acute, margin coarsely and angularly 1- to 4-toothed or lobed; hairy, densely so on the lower surface; upper surface dark green, lower surface light gray-green; stems from 2 to 7 mm. in thickness, cylindrical or somewhat compressed, longitudinally wrinkled, hairy, gray-green; flowers nearly sessile, with an urn-shaped, hairy, unequally 5-toothed calyx and a campanulate corolla, yellowish with purplish veins; fruit, a 2-locular pyxis enclosed in the calyx; odor distinctive; taste bitter and acrid.

For further description see the U. S. P. X.

Assay—Proceed by Type Process B, taking 25 Gm. of Hyoscyamus, in fine powder, using ether-chloroform mixture for percolating the drug and chloroform for the final extraction of the alkaloids. Determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of Hyoscyamus.

This assay is explained on page 1498.

U. S. P. Preparations—Extractum Hyoscyami; Fluidextractum Hyoscyami; Tinctura Hyoscyami.

N. F. Preparation—Pilulæ Catharticæ Vegetabiles (from Extract).

Hyoscyamus contains *hyoscyamine*, $C_{17}H_{23}O_3N$, *hyoscine*, $C_{17}H_{21}ON_4$, *hyoscypicrin*, $C_{27}H_{52}O_{14}$, chlorophyll, mucilage, extractive, etc.

Uses—Hyoscyamus is narcotic, hypnotic, and slightly laxative. Dose, three grains (0.2 Gm.).

HYOSCYAMINÆ HYDROBROMIDUM. U. S. Hyoscyamine Hydrobromide

[Hyoscyamin. Hydrobr.—Hyoscyamine Bromide]

The hydrobromide [$C_{17}H_{23}O_3N.HBr = 370.21$] of hyoscyamine, an alkaloid obtained from hyoscyamus and other plants of the *Solanaceæ*.

Preparation—It is made by dissolving hyoscyamine in diluted hydrobromic acid, evaporating and crystallizing. This salt is somewhat more stable than the sulphate which was formerly official.

Hyoscyamine, the base melts at 108° C. and has an $[a]_D$ −22°, in 50 per cent alcohol. It is only sparingly soluble in ether and in cold water. The base is readily converted into atropine by any alkali.

Description and Physical Properties—White, odorless, deliquescent crystals.

Caution—Hyoscyamine Hydrobromide is extremely poisonous.

Hyoscyamine Hydrobromide is very soluble in water. One Gm. is soluble in 2.5 cc. of alcohol, 1.7 cc. of chloroform, and in 2260 cc. of ether, at 25° C.

Tests for Identity—It melts at about 152° C.

An aqueous solution of Hyoscyamine Hydrobromide is lævorotatory.

Add 5 drops of nitric acid to about 0.01 Gm. of the salt, and evaporate to dryness in a porcelain dish on a water bath: the residue becomes violet upon the addition of alcoholic potassium hydroxide T.S.

Gold chloride T.S. added to about 1 cc. of an aqueous solution of the salt (1 in 20) produces a precipitate which, when recrystallized from a small quantity of boiling distilled water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (*difference from atropine and scopolamine*).

Silver nitrate T.S. added to an aqueous solution of Hyoscyamine Hydrobromide produces a yellowish-white precipitate which is insoluble in nitric acid.

Shake 2 cc. of chloroform with 1 cc. of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine T.S. have been added: the chloroform acquires a brownish color.

Tests for Purity—An aqueous solution of Hyoscyamine Hydrobromide (1 in 20) is neutral to litmus paper.

The ash from 0.1 Gm. is negligible.

Platinic chloride T.S. does not form a precipitate in an aqueous solution of the salt (1 in 20) (*difference from most other alkaloids*).

Dissolve about 0.05 Gm. of the salt in 1 cc. of sulphuric acid: the solution is not darker than faint yellow (*readily carbonizable substances*).

Preserve in well-closed containers, protected from light.

Uses—Hyoscyamine Hydrobromide is used as a narcotic and sedative. The dose is one one-hundredth grain (0.0006 Gm.).

STRAMONIUM. U.S. Stramonium

[**Stramon.**—Jamestown Weed, Jimson Weed]

Stramonium consists of the dried leaves and flowering tops of *Datura Stramonium* Linné (Fam. *Solanaceæ*).

Stramonium yields not less than 0.25 per cent of the alkaloids of Stramonium, contains not more than 3 per cent of stems over 8 mm. in diameter, and yields not more than 4 per cent of acid-insoluble ash.

Description—More or less matted, wrinkled and crushed; leaves petiolate, ovate; apex acuminate, base unequal; margin sinuate, toothed or angled, the teeth few, acute and with rounded sinuses; the lamina usually shows small, circular perforations, surrounded by cork or sometimes filled with cork, surfaces usually sparsely hairy, the hairs mostly upon the veins; upper surface dark green, lower surface light green. Stems often flattened, longitudinally wrinkled, occasionally with one or more deep furrows: light greenish-brown to purplish-brown. Odor distinct, heavy and narcotic; taste unpleasant and nauseous.

For further description see the U. S. P. X.

Assay—Proceed by Type Process B, using 10 Gm. of Stramonium in fine powder, ether-chloroform mixture for percolating the drug, and chloroform as the immiscible solvent for extracting the alkaloids from the aqueous liquid. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of Stramonium.

This assay is explained on page 1499.

U. S. P. Preparations—Extractum Stramonii (Pilular and Powdered); Tinctura Stramonii.

N. F. Preparations—Fluidextractum Stramonii; Unguentum Stramonii.

Stramonium contains *hyoscyamine*, *hyoscine*, and *atropine*; the mixed alkaloids were formerly called *daturine*. The leaves contain albumin, mucilage, malic acid, and potassium nitrate. In the seeds, which are no longer official, there is found about 25 per cent of fixed oil, with resins, mucilage, etc.

History—*Stramonium* was probably known to the ancients as a poison. It certainly has been known and used in India for many centuries. Dioscorides confused it with henbane.

Uses—Stramonium is narcotic and poisonous. Dose, one to three grains (0.06 to 0.2 Gm.).

PILOCARPUS. (U. S. P. IX) Pilocarpus

[Jaborandi]

The dried leaflets of *Pilocarpus Jaborandi* Holmes, known in commerce as Pernambuco Jaborandi, or of *Pilocarpus microphyllus* Stapf, known in commerce as Maranham Jaborandi (Fam. *Rutaceæ*), without the presence or admixture of more than 5 per cent of the stalks bearing the leaflets and stems of the same plant, or other matter, and yielding not less than 0.6 per cent of the alkaloids of Pilocarpus.

Pilocarpus leaves were first employed medicinally about 1874. Since 1900 very little *Pilocarpus jaborandi* has been obtainable, most of the supply now coming from *Pilocarpus microphyllus*.

Description—*Pernambuco Jaborandi*—Leaflets when entire, oval oblong, or elliptical, from 4 to 10.5 cm. in length and from 2 to 4 cm. in breadth and with short, stout petiolules; summits more or less rounded or acute and emarginate; bases rounded or acute and mostly unequal; margins entire and narrowly revolute; very smooth, shiny, coriaceous and glandular-punctate; upper surfaces grayish to brownish-green, midribs mostly depressed, under surfaces yellowish- or greenish-brown and slightly pubescent on the prominent midvein.

Maranham Jaborandi—Leaflets rhomboidally oval to obovate or elliptical, from 1.5 to 5 cm. in length and from 1 to 3 cm. in breadth, the lateral ones nearly sessile, the terminal ones on margined petiolules, from 0.5 to 1.5 cm. in length; of a nearly uniform grayish or yellowish-green color, rather thin but otherwise resembling Pernambuco Jaborandi.

For a further description and assay, see the U. S. P. IX.

Pilocarpus contains *pilocarpine*, $C_{11}H_{16}O_2N_2$, and *isopilocarpine*. *Jaborane*, which was believed to be a definite principle, has been shown to be a mixture of other alkaloids. Several other unimportant alkaloids have been separated from various species of pilocarpus. It also contains a colorless, viscid oil. The leaves are coriaceous and difficult to powder.

Assay—Proceed by Type Process A, taking 15 Gm. of Pilocarpus in fine powder, using 150 cc. of chloroform as the solvent and decanting an aliquot portion of 100 cc. representing 10 Gm. of pilocarpus. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.0208 Gm. of the alkaloids of Pilocarpus.

Uses—It is used as a diaphoretic and sialogogue. Dose, thirty grains (2 Gm.).

PILOCARPINÆ HYDROCHLORIDUM. U.S. Pilocarpine Hydrochloride

[Pilocarpin. Hydrochl.—Pilocarpine Chloride]

The hydrochloride [$C_{11}H_{16}O_2N_2.HCl = 244.67$] of an alkaloid obtained from the dried leaflets of *Pilocarpus Jaborandi* Holmes, or of *Pilocarpus microphyllus* Stapf (Fam. *Rutaceæ*).

Preparation—The total alkaloids are extracted with alcohol containing a small amount of hydrochloric acid. The solvent is distilled off and the aqueous residue filtered, and the filtrate neutralized with ammonia. This is allowed to stand until the resins are all deposited. It is then filtered, and the filtrate evaporated to a small bulk. Ammonia is then added in excess and the free alkaloids removed with chloroform. This solvent is removed by distillation and the residue dissolved in a small quantity of water and nitric acid. The crystals which form are a mixture of pilocarpine and isopilocarpine nitrates and these are separated by recrystallization from alcohol. Other salts are derived from the purified nitrate.

Pilocarpine is in the form of a colorless, oily liquid which boils at 260° C. under 5 mm. It has an $[\alpha]_D$ of +100°. It is soluble in water, alcohol, or in chloroform but practically insoluble in ether.

Description and Physical Properties—Colorless, odorless, translucent crystals. It is hygroscopic.

One Gm. of Pilocarpine Hydrochloride is soluble in 0.3 cc. of water, 3 cc. of alcohol, and in 366 cc. of chloroform, at 25° C. One Gm. is soluble in 1.5 cc. of alcohol at 60° C. It is insoluble in ether.

Tests for Identity—When dried to constant weight at 100° C., Pilocarpine Hydrochloride melts between 195° and 198° C.

Its aqueous solution (1 in 20) is slightly acid to litmus paper.

Dissolve 0.01 to 0.02 Gm. of Pilocarpine Hydrochloride in 2 cc. of distilled water in a test tube, add 2 cc. of a faintly acid hydrogen dioxide T.S., and cover the mixture with about 1 cc. of benzene. Add 3 or 4 drops of a solution of potassium dichromate (1 in 300) and shake the mixture gently: the benzene layer acquires a violet color, while the aqueous layer remains yellow (*distinction from other alkaloids*). (If more than 0.02 Gm. of the salt is used, the benzene turns blue and the reaction is no longer characteristic.)

Silver nitrate T.S. produces in an aqueous solution of the salt, a white precipitate, insoluble in nitric acid.

Tests for Purity—The ash from 0.1 Gm. is negligible.

A solution of 0.1 Gm. of Pilocarpine Hydrochloride in 2 cc. of sulphuric acid is colorless or at most faintly yellow (*readily carbonizable substances*).

The addition of ammonia T.S. or of potassium dichromate T.S. to 10 cc. of an aqueous solution of the salt (1 in 100) produces no turbidity (*various foreign alkaloids*).

Preserve in well-closed containers, protected from light.

Uses—Pilocarpine Hydrochloride is a diaphoretic and sialogogue. Dose, by mouth, one-sixth of a grain (0.01 Gm.) but preferably given hypodermically in doses of one-twelfth grain (0.005 Gm.).

PILOCARPINÆ NITRAS. U.S. Pilocarpine Nitrate

[Pilocarpin. Nit.]

The nitrate [$C_{11}H_{16}O_2N_2.HNO_3$] of an alkaloid obtained from the dried leaflets of *Pilocarpus Jaborandi* Holmes, or of *Pilocarpus microphyllus* Stapf (Fam. *Rutaceæ*).

Preparation—See *Pilocarpinæ Hydrochloridum*, above.

Description and Physical Properties—Shining, colorless crystals. It is stable in the air.

One Gm. of Pilocarpine Nitrate is soluble in 4 cc. of water and in 75 cc. of alcohol, at 25° C. One Gm. is soluble in 21 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether.

Tests for Identity—Pilocarpine Nitrate melts between 170° and 173° C.

Its aqueous solution (1 in 20) is slightly acid to litmus paper.

Dissolve from 0.01 to 0.02 Gm. of Pilocarpine Nitrate in 2 cc. of distilled water in a test tube, add 2 cc. of a faintly acid hydrogen dioxide T.S., and cover the mixture with about 1 cc. of benzene. Add 3 or 4 drops of a solution of potassium dichromate (1 in 300) and shake the mixture gently: the benzene layer acquires a violet color, while the aqueous layer remains yellow (*distinction from other alkaloids*). (If more than 0.02 Gm. of the salt is used, the benzene turns blue and the reaction is no longer characteristic.)

Mix an aqueous solution of the salt with an equal volume of ferrous sulphate T.S., and superimpose the mixture upon 5 cc. of sulphuric acid, contained in a test tube: the line of contact becomes brown.

Tests for Purity—The ash from 0.1 Gm. is negligible.

A solution of 0.1 Gm. of Pilocarpine Nitrate in 2 cc. of sulphuric acid is colorless or at most only faintly yellow (*readily carbonizable substances*).

The addition of a few drops of silver nitrate T.S. to 5 cc. of an aqueous solution of the salt (1 in 50), acidulated with nitric acid, does not at once produce an opalescence (*chloride*).

The addition of ammonia T.S. or of potassium dichromate T.S. to 10 cc. of an aqueous solution of Pilocarpine Nitrate (1 in 100) produces no turbidity (*various foreign alkaloids*).

Preserve in well-closed containers, protected from light.

Uses—Pilocarpine Nitrate is used as a diaphoretic and sialogogue. The dose is the same as for the hydrochloride.

COLCHICI CORMUS. U. S. Colchicum Corm

[**Colch. Corm.**—COLCHICUM ROOT]

The dried corm of *Colchicum autumnale* Linné (Fam. *Liliaceæ*), yielding not less than 0.35 per cent of colchicine.

Description—Usually in reniform transverse slices or in ovate longitudinal slices from 2 to 5 mm. in thickness; flat surfaces whitish, slightly roughened, and of a crystalline appearance under a hand lens; epidermal surface light brown and finely wrinkled; fracture short and mealy; odor slight; taste bitter and acrid.

For further description see the U. S. P. X.

Powdered Colchicum Corm—Light brown or grayish-brown; starch grains numerous, single or 2- to 6-compound, the individual grains varying from spherical or ovoid to polygonal, from 0.003 to 0.030 mm. in diameter and marked with a triangular or star-shaped central cleft; tracheæ few and with spiral or scalariform thickenings; occasional fragments of epidermal cells with thin, reddish-brown walls.

Assay—Proceed as directed under *Colchici Semen.*

U. S. P. Preparation—Extractum Colchici Cormi.

N. F. Preparations—Fluidextractum Colchici Cormi; Tinctura Colchici Cormi Fortior.

Uses—For uses see Colchicum Seed.

COLCHICI SEMEN. U. S. Colchicum Seed

[**Colch. Sem.**—COLCHICI SEMEN P. I.]

Colchicum Seed is the dried ripe seed of *Colchicum autumnale* Linné (Fam. *Liliaceæ*).

Colchicum Seed yields not less than 0.45 per cent of colchicine.

Description—Ovoid or irregularly globular, minutely pointed at the hilum, and with a distinct beak or caruncle approximately opposite to the hilum; from 2 to 3 mm. in diameter and, when fresh, with a tendency to cohere in small clumps; externally dark brown, finely pitted; tough and of bony hardness; internally whitish or light brown; nearly inodorous; taste bitter and acrid.

For further description see the U. S. P. X.

Assay—Place 15 Gm. of Colchicum Seed, in fine powder, in a 500 cc. flask, and add 290 cc. of distilled water and 10 cc. of solution of lead subacetate. Weigh the flask and contents, and digest the mixture at from 60° to 70° C. for three hours with occasional agitation. Cool, add distilled water to restore the original weight, and filter off 200 cc. Add 2 Gm. of sodium phosphate to the clear filtrate, or sufficient to completely precipitate the lead, shake the mixture frequently during half an hour, and filter off 100 cc., representing 5 Gm. of Colchicum Seed. Shake out the alkaloid from the filtrate with chloroform until completely extracted, as shown by testing with iodine T.S., and evaporate the chloroform solution. Add about 1 cc. of alcohol, and again evaporate. Repeat this operation once more, and dry the residue to constant weight at 100° C. To this weighed residue contained in a flask add 5 cc. of tenth-normal sulphuric acid and 5 cc. of distilled water, adding a few drops of chloroform, and heat the mixture for ten minutes at 70° C. Filter the liquid through a pledget of purified cotton, wash the flask and cotton with distilled water, reject the filtrate and washings, and remove as much of the water from the cotton as possible. Dissolve any insoluble residue that may remain on the cotton by

washing it first with a little alcohol and then with ether; collect the alcohol-ether washings in the flask, evaporate, and dry the residue to constant weight at 100° C. Deduct this weight from the weight of residue previously obtained. The difference will be the weight of colchicine obtained from 5 Gm. of Colchicum Seed (Proximate Assays, page 1497).

U. S. P. Preparations—Fluidextractum Colchici Seminis; Tinctura Colchici Seminis.

The alkaloid *colchicine*, $C_{22}H_{25}O_6N$, is found in both the corm and seed of colchicum. It is the active principle. There has been extracted a second alkaloid *colchiceine*, $C_{21}H_{23}O_6N.\frac{1}{2}H_2O$, the actual presence of which is doubtful as colchicine can be readily converted into it by heating with dilute sulphuric acid. There are present in the corm, starch, fat, sugar, resin, etc. In the seed, a fixed oil is found in addition to the other principles. The toughness of the seeds is due to their composition and structure, being composed chiefly of horny albumin made up of cells having very thick walls and surrounded by a closely adherent testa. The seeds may be exhausted of their active principle by digesting them in hot alcohol without bruising or powdering them.

Uses—Colchicum is used in gout and rheumatism. Dose of the seeds, three grains (0.2 Gm.); of the corm, four grains (0.25 Gm.).

COLCHICINA. U. S. Colchicine

An alkaloid [$C_{22}H_{25}O_6N = 399.32$] obtained from the seed or corm of colchicum.

Preparation—Colchicine may be made by percolating colchicum with alcohol, evaporating the percolate, diluting with water, filtering, precipitating the coloring matter with lead subacetate, treating the liquid with sodium phosphate to remove lead compounds, and precipitating the colchicine with tannic acid; the tannate is then digested with lead oxide, dried, and the colchicine dissolved out with alcohol. Colchicine forms with chloroform an additive product. It is soluble in water, dilute alcohol, and in chloroform. When crystallized from ethyl acetate, it has a melting point of 155° to 157° C. and has an $[a]_D$ of −120°, in chloroform.

Description and Physical Properties—Pale yellow, amorphous scales, or powder, turning darker on exposure to light. It is odorless, or nearly so.

Caution—Colchicine is extremely poisonous.

One Gm. of Colchicine is soluble in 22 cc. of water, 220 cc. of ether, and in 100 cc. of benzene, at 25° C. It is freely soluble in alcohol and in chloroform, and is insoluble in petroleum benzin.

Tests for Identity—Colchicine melts between 142° and 146° C.

Its aqueous solution (1 in 30) is neutral to litmus paper, and is lævorotatory.

An aqueous solution of Colchicine (1 in 30) is yellow, its color becoming intensified by the addition of inorganic acids.

Mix about 0.001 Gm. of Colchicine with a few drops of sulphuric acid: a lemon-yellow color is produced, which, on the addition of a drop of nitric acid, changes to greenish-blue, rapidly becoming reddish and finally yellow, or almost colorless. On adding an excess of sodium hydroxide T.S., the color is changed to red.

Tests for Purity—The addition of 2 drops of ferric chloride T.S. to 5 cc. of an aqueous solution of Colchicine (1 in 100) produces no color (*colchiceine*), but on heating, a brownish-red color is developed, which changes to brownish-black. One drop of ferric chloride T.S. added to 1 cc. of an alcoholic solution of Colchicine (1 in 20) at once produces a garnet-red color.

The ash from 0.1 Gm. is negligible.

Heat the mixture of about 0.01 Gm. of Colchicine, 2 cc. of sodium hydroxide T.S., and one drop of aniline: no odor of phenylisocyanide is developed (*chloroform*).

Preserve in well-closed containers, protected from light.

History—This drug is referred to by Dioscorides who simply knew it as a poison. It was called *Hermodactylus* by several writers in the sixth and seventh centuries and was recommended at that time in the treatment of gout. It was the basis of a celebrated proprietary remedy in the latter part of the eighteenth century, which was put up in 2 drachm bottles (containing

two doses) which sold for the equivalent of $4.00 a bottle. The preparation was called Hasson's *Eau Medicinale*. Its composition was exposed shortly after the beginning of the nineteenth century.

Uses—Colchicine is used in the treatment of gout and rheumatism. Dose, one one-hundred-and-twentieth of a grain (0.0005 Gm.).

VERATRUM VIRIDE. U. S. Veratrum Viride

[Verat. Vir.—Green Hellebore, American Hellebore]

Veratrum Viride consists of the dried rhizome and roots of *Veratrum viride* Aiton (Fam. *Liliaceæ*).

Veratrum Viride contains not more than 5 per cent of its stems or other foreign organic matter, and yields not more than 4 per cent of acid-insoluble ash.

Description—Rhizome more or less conical, from 2 to 7 cm. in length, from 1.5 to 3 cm. in diameter, externally light to dark brown or brownish-black; frequently bearing at the summit numerous, thin, closely-arranged leaf bases, otherwise rough and wrinkled and somewhat annulate from scars of bud scales; inodorous; taste bitter and acrid. Roots numerous, nearly cylindrical, from 3 to 8 cm. in length and from 1 to 4 mm. in diameter, usually brittle, whitish and more or less starchy.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Veratri Viridis.

The U. S. P. formerly included under the name of Veratrum both *Veratrum album* and *Veratrum viride*, but, as the two drugs do not possess identical therapeutic value recent pharmacopœias have recognized only the latter.

Veratrum viride contains the alkaloids *jervine*, *pseudojervine*, *rubijervine*, and *cevadine*. The most active of these appears to be *cevadine*, which is very poisonous and sternutatory. It contains also a bitter glucoside, *veratramarin*, and *jervic acid*. It is claimed that *cevadine* is not present in *Veratrum album*, while the other constituents are present in both. Cevadine is also known as *crystallized veratrine* to distinguish it from the mixture of alkaloids known as *veratrine*.

Veratrum album contains *protoveratrine* which is similar to cevadine in its action, though even more toxic. There are also present resins, starch, coloring matter, etc.

Uses—It is a cardiac sedative, poisonous, with emetic and diaphoretic properties. Dose, one to two grains (0.06 to 0.125 Gm.).

VERATRINA. N. F. Veratrine

(U. S. P. IX)

[Veratrin.—Veratria]

A mixture of alkaloids obtained from the seed of *Asagræa officinalis* (Chamisso and Schlechtendal) Lindley (Fam. *Liliaceæ*). Preserve it in well-closed containers, protected from light.

Preparation—The seeds are exhausted with alcohol, and the alcohol recovered by distillation. The residuary liquid contains veratrine in its natural combination with veratric acid; this is diluted with water (which precipitates the resins) and filtered; potassium hydroxide or ammonia is added to the filtrate, when veratrine is precipitated. It is then redissolved, decolorized, and reprecipitated.

The official *Veratrine* consists of a mixture of *cevadine*, *cevadilline*, *sabadine*, *sabadinine* and *veratridine*. It is entirely different from *crystallized veratrine*, which is another name for pure *cevadine*.

Official Description—It is a white, or grayish-white, amorphous powder. It is slightly hygroscopic.

Odor, Taste, and Reaction—Odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane. *Great caution must be used in tasting it.* Its alcoholic solution is alkaline to moistened litmus paper.

Solubility—One Gm. of Veratrine dissolves in 1760 cc. of water, 2.8 cc. of alcohol, 0.7 cc. of chloroform, and in 4.2 cc. of ether at 25° C. (77° F.); also in 1345 cc. of water at 80° C. (176° F.); insoluble in petroleum benzin.

Tests for Identity—Triturate about 0.05 Gm. of Veratrine with 2 cc. of sulphuric acid in a glass mortar; the yellow or orange-red solution exhibits by reflected light a greenish fluorescence, which becomes more intense upon the addition of an equal volume of sulphuric acid. Upon standing, the solution gradually assumes a deep red color.

Sulphuric acid, when heated with Veratrine, gives a cherry-red color. Sulphuric acid added to a mixture of one part of Veratrine and six parts of sucrose produces a green color, which changes to blue, and finally the mixture becomes colorless.

No weighable ash remains on incinerating 0.1 Gm. of Veratrine.

Impurities and Test for Impurities—An alcoholic solution of Veratrine (1 in 20) remains clear after the addition of platinic chloride T.S. (*various foreign alkaloids*).

N. F. Preparations—Oleatum Veratrinæ; Unguentum Veratrinæ.

Uses—Veratrine is used externally in neuralgia, rheumatism, etc. It is sternutatory and very poisonous.

ACONITUM. U. S. Aconite

[**Aconit.**—Monkshood, Aconite Root, Aconiti tuber P. I.]

Aconite, in the form of the tincture, administered subcutaneously to guinea pigs, has a minimum lethal dose not exceeding 0.0004 cc. of tincture for each gram of body weight of guinea pig. Aconite contains not more than 5 per cent of its stems or 2 per cent of other foreign organic matter.

Description—More or less conical or fusiform, from 4 to 10 cm. in length, and from 1 to 3.5 cm. in diameter at the crown; externally dark brown or grayish-brown, smooth or longitudinally wrinkled, the upper end with a bud, or remains of bud-scales and a stem-scar, the other portions with numerous root-scars or short rootlets; fracture short, horny or somewhat mealy; internally whitish, light brown or dark brown; bark, 1 to 2 mm. in thickness, cambium zone usually 5- to 8-angled; odor very slight, taste sweetish, soon becoming acrid and developing a tingling sensation, followed by numbness. (*Taste cautiously.*)

Assay—The details of this assay will be found on page 1506 with explanations.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Aconiti.

N. F. Preparations—Linimentum Aconiti et Chloroformi (from Fluidextract); Fluidextractum Aconiti.

Aconite is found both on the European and American continents. It has been used medicinally since medieval times and is said to have been used as an arrow poison by the Chinese.

The drug contains aconitine, $C_{34}H_{47}O_{11}N$, as its principal alkaloid. Several others are present namely, *benzaconine*, (*benzolaconine*), *aconine*, and *methyl benzolaconine*. These are all decomposition products. The physiologic action of the other alkaloids is antagonistic to aconitine. Aconitine is readily decomposed into the other alkaloids which are inert or less active and for this reason the U. S. P. X has a biological standard for the drug and its preparations to indicate the minimum activity. *Aconitic acid*, $H_6C_6O_6$, is also present, together with resins, sugar, fat, coloring matter, etc. Aconitic acid may be produced by heating citric acid to 155° C. (311° F.). Alcohol is the best menstruum for preparations of aconite.

Uses—Aconite is a cardiac and nerve sedative, producing numbness and tingling when applied to the tongue or lips. It is very poisonous. Dose, one-half grain (0.03 Gm.).

ACONITINA. U. S. Aconitine

[**Aconitin.**]

An alkaloid [$C_{34}H_{47}O_{11}N$ = 645.55] obtained from aconite. Aconitine, administered subcutaneously to guinea pigs, has a minimum lethal dose of not less than 0.00,000,005,5 Gm. and not more than 0.00,000,006,5 Gm. for each gram of body weight of guinea pig.

Preparation—Aconitine may be made by acidifying an alcoholic tincture of aconite with tartaric acid to remove resin and fatty matter, precipitating the filtrate with sodium bicarbonate, dissolving the precipitate in ether, and crystallizing.

The base has an $[a]_D$ of $+14.6°$ in chloroform. Aconitine salts, when heated to 120° to 130° C., in aqueous solution under pressure, yield, first acetic acid and benzoylaconine and finally benzoic acid and aconine.

Description and Physical Properties—Colorless or white crystals. It is odorless and is stable in the air.

Caution—Aconitine is extremely poisonous.

Aconitine is very slightly soluble in water. One Gm. dissolves in 28 cc. of alcohol, in about 65 cc. of ether, and in 7 cc. of benzene, at 25° C. It is almost insoluble in petroleum benzin.

Tests for Identity—Aconitine melts at about 195° C. when heated rapidly.

Solutions of Aconitine in neutral solvents are slightly alkaline to litmus paper.

About 0.001 Gm. of Aconitine mixed with 2 or 3 drops of nitric or sulphuric acid on a white porcelain surface dissolves without coloration. Under the same conditions, 0.001 Gm. of Aconitine mixed with 2 drops of sulphuric acid containing 0.005 Gm. of ammonium vanadate in each cc. produces an orange color.

Dilute solutions of Aconitine salts yield precipitates with mercuric potassium iodide T.S., tannic acid T.S., and gold chloride T.S., but only concentrated solutions yield precipitates with platinic chloride T.S., mercuric chloride T.S., and trinitrophenol T.S.

Tests for Purity—The ash from 0.05 Gm. is negligible.

Evaporate to dryness on a water bath about 0.01 Gm. of Aconitine with 5 drops of fuming nitric acid, cool and treat the resulting yellow residue with alcoholic potassium hydroxide T.S.: no violet color develops (*pseudaconitine or atropine*).

Assay—The details of this assay will be found on page 1506 with explanations.

Preserve in well-closed containers, protected from light.

Uses—*Crystallized* aconitine is a *very powerful poison.* It is given in the dose of one four-hundredth of a grain (0.00015 Gm.). Amorphous or commercial aconitine is usually an impure product. It is a cardiac and nerve sedative.

HYDRASTIS, U. S. Hydrastis

[Golden Seal]

Hydrastis consists of the dried rhizome and roots of *Hydrastis canadensis* Linné (Fam. *Ranunculaceæ*).

Hydrastis yields not less than 2.5 per cent of the ether-soluble alkaloids of Hydrastis and contains not more than 2 per cent of its stems and leaves, or more than 2 per cent of other foreign organic matter, and yields not more than 3 per cent of acid-insoluble ash.

Description—Rhizome subcylindrical, flexuous, from 1 to 5 cm. in length and from 2 to 10 mm. in thickness; more or less annulate and wrinkled longitudinally; yellowish-brown to dark grayish-brown; marked by numerous stem scars or occasional stem- or leaf-bases and numerous roots, frequently broken, leaving circular yellowish scars or short protuberances; fracture short and waxy; internally deep yellow or greenish-yellow; odor distinctive; taste bitter.

Roots numerous, filiform, up to 35 cm. in length and 1 mm. in diameter; yellowish; brittle; curved, twisted and matted together or broken into pieces.

Assay—Proceed by Type Process A, taking 10 Gm. of Hydrastis, in fine powder, using 100 cc. of ether and decanting an aliquot portion of 50 cc., representing 5 Gm. of Hydrastis. Use ether for the final extraction, and determine the alkaloids gravimetrically.

This assay is explained on page 1498.

U. S. P. Preparation—Fluidextractum Hydrastis.

N. F. Preparations—Extractum Hydrastis; Mistura Rhei Alkalina (from Fluidextract); Tinctura Hydrastis.

Hydrastis contains *hydrastine*, $C_{21}H_{21}O_6N$, *berberine*, $C_{20}H_{17}O_4N$, and *canadine*, $C_{20}H_{21}O_4N$, sugar, starch, resin, coloring matter, etc. Hydrastis usually contains at least 1.5 per cent of hydrastine and 2.5 per cent of berberine. The ether-soluble alkaloids upon which the value of the drug is based are

hydrastine and canadine. The salts of hydrastine are white; those of berberine are bright yellow.

Uses—Hydrastis is used as an alterative and tonic, in doses of twenty to forty grains (1.3 to 2.6 Gm.).

HYDRASTINÆ HYDROCHLORIDUM. N. F. Hydrastine Hydrochloride

[**Hydrastin. Hydrochl.**—HYDRASTINE CHLORIDE]

The hydrochloride [$C_{21}H_{21}O_6N.HCl = 419.75$] of the alkaloid hydrastine.

Preparation—It may be made by adding hydrochloric acid carefully to hydrastine in aqueous mixture until a neutral solution results, then concentrating and crystallizing.

Official Description—It occurs as a white to creamy-white powder; hygroscopic.

Odor and Reaction—Odorless. An aqueous solution of the salt (1 in 20) is neutral or only slightly acid to litmus.

Solubility—Hydrastine Hydrochloride is very soluble in water and in alcohol; slightly soluble in chloroform; very slightly soluble in ether.

Tests for Identity—An aqueous solution of the salt yields with silver nitrate T.S. a white precipitate insoluble in nitric acid, but soluble in ammonia water. Sulphuric acid, when added to Hydrastine Hydrochloride, produces a yellow color which turns to purple on heating. Sulphuric acid containing 0.005 Gm. of molybdic acid in each cc. produces with hydrastine salts a green color, changing to olive-green, then to brown; nitric acid produces a reddish-yellow color; sulphuric acid containing 0.005 Gm. of selenous acid in each cc. gives a light green color changing to brown.

Tests for Purity—No weighable ash remains on incinerating 0.1 Gm. of Hydrastine Hydrochloride. A solution of about 0.1 Gm. of Hydrastine Hydrochloride in 10 cc. of diluted sulphuric acid shows no blue fluorescence (*hydrastine*) but on the gradual addition of potassium permanganate T.S., avoiding excess, a blue fluorescence develops.

An aqueous solution of Hydrastine Hydrochloride (1 in 20) is not reddened by chlorine water (*berberine*).

Preserve it in well-closed containers, protected from light.

N. F. Preparation—Liquor Hydrastinæ Compositus.

Uses—Same uses and dose as hydrastine.

LIQUOR HYDRASTINÆ COMPOSITUS. N. F. Compound Solution of Hydrastine

[**Liq. Hydrastin. Co.**—COLORLESS HYDRASTINE SOLUTION]

	Metric	Alternative
Hydrastine Hydrochloride	**3 Gm.**	22 gr.
Aluminum Chloride	**3 Gm.**	22 gr.
Calcium Chloride	**3 Gm.**	22 gr.
Magnesium Chloride	**3 Gm.**	22 gr.
Potassium Chloride	**1 Gm.**	7 gr.
Glycerin	**500 cc.**	8 fl. oz.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	16 fl. oz.

Dissolve the salts in 450 cc. [7 fl. 96 min.] of distilled water, add the glycerin, filter, and add sufficient distilled water to make the product measure 1000 cc. [16 fl. oz.].

Compound Solution of Hydrastine is a straw-colored liquid with a saline taste. It is acid to litmus paper.

Specific gravity: about 1.127 at 25° C.

Evaporate 10 cc. of the solution at a temperature not exceeding 100° C.: it leaves a thick, viscous residue not exceeding 5.714 Gm.

Incinerate the residue from 10 cc. of the solution: it leaves not more than 0.038 Gm. of ash.

A solution of sodium carbonate added to the Solution produces a white gelatinous precipitate.

Uses—It is used as an alterative, astringent, and antiseptic in a dose of one fluidrachm (4 cc.)

Average dose—1 fluidrachm (4 cc.).

GRANATUM. U. S. Pomegranate

[Granat.—Pomegranate Bark]

Pomegranate is the dried bark of the stem or root of *Punica Granatum* Linné (Fam. *Granaceæ*).

Pomegranate contains not more than 2 per cent of wood or other foreign organic matter.

Description—Stem bark in pieces from 2 to 8 cm. in length; bark from 0.5 to 3.5 mm. in thickness; outer surface yellowish to grayish-brown, with patches of grayish lichens, broadly elliptical lenticels and yellow-brown furrows or abraded patches of cork; longitudinally wrinkled; inner surface light yellow or yellowish-brown, finely striate; fracture short; phelloderm dark green; inner bark yellowish-green.

Root bark in transversely curved pieces; externally brownish-yellow with conchoidal depressions and dark brown irregular patches in the cork; internally dark yellow, the medullary rays extending nearly to the outer surface.

In either root or stem bark, odor slight, taste astringent, somewhat bitter and nauseous.

For further description see the U. S. P. X.

Preserve in tightly-closed containers.

U. S. P. Preparation—Fluidextractum Granati.

Pomegranate contains four alkaloids, *pelletierine*, $C_8H_{15}ON$, *isopelletierine*, *pseudopelletierine* and *methylisopelletierine*. The first named is sometimes called *punicine*; the mixed alkaloids are official in the form of pelletierine tannate; pseudopelletierine is solid and crystallizable; the others are liquid. The total alkaloidal content of the bark is about 2.5 per cent. Of this about 0.5 per cent is pelletierine which is said to be toxic to the tapeworm. It also contains punicotannic acid, $C_{20}H_{16}O_{13}$, sugar, mannite, pectin, gum, etc.

Uses—Pomegranate is anthelmintic, in doses of thirty grains (2 Gm.).

PELLETIERINÆ TANNAS. U. S. Pelletierine Tannate

[Pellet. Tann.]

A mixture in varying proportions of the tannates of four alkaloids (pelletierine, iso-pelletierine, methyl-iso-pelletierine, and pseudo-pelletierine), obtained from pomegranate.

Preparation—Pelletierine tannate may be made by precipitating a solution of a sulphate of the alkaloids from pomegranate bark with a solution of tannic acid containing ammonia, washing and drying the precipitate.

Description and Physical Properties—A light yellow, odorless, amorphous powder, having an astringent taste.

One Gm. of Pelletierine Tannate is soluble in about 250 cc. of water at 25° C.

It is soluble in alcohol, slightly soluble in ether, and insoluble in chloroform.

It is dissolved by warm dilute acids.

Test for Identity—Its saturated, aqueous solution is acid to litmus paper. A saturated aqueous solution of the salt is colored blue-black by ferric chloride T.S.

Tests for Purity—The ash from 0.2 Gm. is negligible.

Platinic chloride T.S. produces no precipitate in a cold solution of about 0.1 Gm. of Pelletierine Tannate in a mixture of 4 cc. of distilled water and 1 cc. of diluted hydrochloric acid (*many foreign alkaloids*).

Dissolve about 0.5 Gm. of Pelletierine Tannate, accurately weighed, in 5 cc. of sodium hydroxide T.S., and shake the solution with four successive portions of 10, 5, 5, and 5 cc. of chloroform. Acidulate the combined chloroform solutions with 0.1 cc. of hydrochloric acid, evaporate to apparent dryness on a water bath, dissolve the residue in 5 cc. of alcohol, again evaporate and dry for one hour at 60° C. The weight of the residue is not less than 20 per cent of the weight taken.

Stir about 0.001 Gm. of the residue obtained in the preceding test on a white, porcelain surface with 2 drops of sulphuric or nitric acid: no other than a light yellow or slightly brown color is produced.

Preserve in small, well-closed containers, protected from light.

Uses—Pelletierine tannate is used as a tænifuge. Dose, four grains (0.25 Gm.).

IPECACUANHA. U. S. Ipecac

[Ipecac.—Ipecachuanhæ Radix P. I.]

Ipecac consists of the dried rhizome and roots of *Cephaëlis Ipecacuanha* (Brotero) A. Richard, known in commerce as Rio or Brazilian Ipecac, or of *Cephaëlis acuminata* Karsten, known in commerce as Cartagena or Panama Ipecac (Fam. *Rubiaceæ*).

Ipecac yields not less than 1.75 per cent of the ether-soluble alkaloids of ipecac and contains not more than 5 per cent of its over-ground stems, or more than 2 per cent of other foreign organic matter.

Description—Roots in cylindrical pieces, mostly curved and sharply flexuous, occasionally branched, from 3 to 15 cm. in length, from 1 to 4 mm. in thickness, reddish-brown to dark brown, either smooth or closely annulated, with thickened, incomplete rings and usually exhibiting transverse fissures with vertical sides; bark of smooth root thin, approximately one-ninth of the diameter of the root, that of the annulated root approximately two-thirds of the entire diameter. Fracture of bark short, easily separable from the tough, fibrous wood; odor distinctive, the dust sternutatory; taste bitter, nauseous and acrid. Rhizomes cylindrical, attaining a length of 10 cm. and a thickness of 2 mm., finely longitudinally wrinkled, with a few elliptical scars and a distinct pith approximately one-sixth of the entire diameter.

For further description see the U. S. P. X.

Assay—Proceed by Type Process A, taking 10 Gm. of Ipecac, using 100 cc. of ether and decanting an aliquot portion of 50 cc., representing 5 Gm. of Ipecac. Use ether for the final extraction and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.024 Gm. of the ether-soluble alkaloids of Ipecac.

This assay is explained on page 1498.

U. S. P. Preparations—Fluidextractum Ipecacuanhæ; Pulvis Ipecacuanhæ et Opii; Syrupus Ipecacuanhæ (from Fluidextract).

N. F. Preparations—Mistura Rhei Composita (from Fluidextract): Pilulæ Laxativæ Compositæ; Syrupus Asari Compositus (from Fluidextract); Syrupus Ipecacuanhæ et Opii (from Tincture); Tinctura Ipecacuanhæ et Opii (from Fluidextract).

Ipecac contains *emetine* (*methyl-cephaëline*), $C_{15}H_{22}O_2N$, *cephaëline*, $C_{14}H_{19}O_2N$, *psychotrine*, *emetamine*, also *ipecacuanhic acid*, pectin, starch, resin, sugar, etc. All of the alkaloids are interrelated and may be synthesized from each other. Brazilian roots yield as much as 2.5 per cent of total alkaloids and Cartagena root 2.0 per cent. The apothegmatic matter, which is dissolved by hydroalcoholic liquids when percolating it, is slowly precipitated when added to water or syrup. It may be separated by allowing the aqueous liquid to stand until the separation is completed and then filtering.

History—The first mention of this Brazilian drug is by *Purchas*, a famous traveler, in 1625. Its first introduction into European medicine was in 1686 when Louis XIV purchased from a quack named *Helvetius* the secret of a nostrum used successfully in the treatment of diarrhea and dysentery, and ipecac was found to be the essential ingredient.

Uses—Ipecac is an emetic, in doses of fifteen grains (1 Gm.), and an expectorant, in doses of one grain (0.06 Gm.).

EMETINÆ HYDROCHLORIDUM. U. S. Emetine Hydrochloride

[Emet. Hydroch.]

The hydrochloride [$C_{30}H_{44}O_4N_2.2HCl = 569.46$] of an alkaloid obtained from ipecac or prepared synthetically. It contains variable amounts of water of crystallization. Pelletier and Magendie, the celebrated French scientists, discovered this alkaloid in 1817.

Preparation—The total alkaloids are prepared by extracting the roots with alcohol, evaporating the solution, and shaking out with ether to remove fat and resin. The purified aqueous solution is now made alkaline with ammonia and the alkaloids removed with ether. Cephaëline, which is a phenolic base

is removed with sodium hydroxide, leaving the emetine in the ethereal solution. The salt may be prepared by adding just sufficient diluted hydrochloric acid to emetine, concentrating the solution, and setting it aside to crystallize.

Description and Physical Properties—A white or very slightly yellowish, odorless, crystalline powder.

Emetine Hydrochloride is freely soluble in water and in alcohol.

Tests for Identity—An aqueous solution of the salt (1 in 100) yields precipitates with iodine T.S., with mercuric potassium iodide T.S., or with platinic chloride T.S.

Sulphuric acid, containing in each cc. about 0.005 Gm. of molybdic acid, when added to Emetine Hydrochloride produces a bright green color.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 2) a white precipitate insoluble in nitric acid.

Tests for Purity—The ash from 0.2 Gm. is negligible.

Emetine Hydrochloride dried to constant weight at 100° C. loses not more than 19 per cent (*water*).

A solution of 0.1 Gm. of Emetine Hydrochloride in 10 cc. of distilled water requires for neutralization not more than 0.5 cc. of fiftieth-normal sodium hydroxide, using 1 drop of methyl red T.S. as indicator.

One-tenth of 1 Gm. of the salt dissolves in 2 cc. of sulphuric acid without producing more than a faint yellow color (*readily carbonizable substances*).

Dissolve 0.2 Gm. of Emetine Hydrochloride in 10 cc. of water, add 5 cc. of sodium hydroxide T.S. and shake, successively, with 20 cc. of ether, and then with 10 cc. portions of ether, until the residue obtained by evaporating 2 cc. of the last ether extraction, when dissolved in 1 drop of diluted hydrochloric acid and 1 cc. of water, no longer yields a distinct turbidity with iodine T.S. Discard the ether solutions, acidulate the aqueous liquid with diluted sulphuric acid, add ammonia T.S. until alkaline, and shake with four successive 10 cc. portions of ether. Evaporate the combined ether solutions to dryness on a water bath, and dry the residue at 100° C. Its weight does not exceed 0.004 Gm. (*cephaëline*).

Preserve in dark amber-colored vials, protected from light.

Uses—It is used as a specific agent against the various forms of ameba that cause dysentery and pyorrhea alveolaris. It is usually administered hypodermically. Dose, one-third to one grain (0.02 to 0.06 Gm.).

Unofficial Ipecac Preparations

Emetine Bismuth Iodide, N. N. R.—Emetinæ Bismutho-Iodidum—*Emetine Bismuthous Iodide*—*Bismuth Emetine Iodide*—A complex iodide of emetine and bismuth containing from 17 to 23 per cent of anhydrous emetine and from 15 to 20 per cent of bismuth.

Emetine bismuth iodide is an odorless, orange-red powder having a slightly bitter taste.

It is but slightly soluble (with decomposition and liberation of emetine) in water, and dilute acids. It is decomposed by alkaline liquids and by strong acids.

Uses—Emetine bismuth iodide has the action of emetine; but when taken by the mouth, on account of its limited solubility, it is less likely to cause vomiting than the soluble salts of emetine administered by mouth.

It has been used with apparently good results in the treatment of chronic cases and carriers of amebic dysentery, even when the hypodermic administration of emetine had failed.

Dose—The commonly used dose has been 3 grains (0.2 Gm.) daily for four days, either in a single dose at the midday meal, or in divided doses. The drug should be given as dry powder, enclosed in capsules or cachets as desired, or in the form of pills or capsules which resist disintegration in the stomach.

Alcresta Ipecac—A form of ipecac alkaloids adsorbed with Lloyd's reagent, rendering the drug insoluble in the stomach but soluble in the intestinal secretions. It is especially useful in the treatment of endomebic dysentery. Dose, 1 to 3 tablets. Manufactured by Eli Lilly and Company.

COCAINA. U. S. Cocaine

[**Cocain.**]

An alkaloid [$C_{17}H_{21}O_4N = 303.26$] obtained from the leaves of *Erythroxylon Coca* Lamarck and other species of *Erythroxylon* (Fam. *Erythroxylaceæ*).

Preparation—It may be made by moistening ground coca leaves with solution of sodium hydroxide, percolating with petroleum benzin, shaking the liquid with diluted sulphuric acid, and adding to the separated acid solution an excess of sodium hydroxide. The precipitated cocaine is purified by recrystallization. Cocaine can be made synthetically by treating benzoylecgonine, obtained naturally or by synthesis from cinnamyl cocaine, with hydrochloric or sulphuric acids in the presence of methyl alcohol. The greater part of the alkaloid manufactured in Germany is prepared from cinnamyl cocaine which is obtained from Java coca leaves. The alkaloid has an $[a]_D$ of $-15.8°$.

Description and Physical Properties—Colorless crystals, or a white, crystalline powder. It is odorless, and is stable in the air.

One Gm. of Cocaine is soluble in about 600 cc. of water, 6.5 cc. of alcohol, 0.7 cc. of chloroform, 3.5 cc. of ether, 12 cc. of olive oil, and in 30 to 50 cc. of liquid petrolatum, at 25° C. One Gm. is soluble in 270 cc. of water at 80° C. It is very soluble in warm alcohol.

Tests for Identity—Cocaine melts between 96° and 98° C.

Its saturated aqueous solution is alkaline to litmus paper.

Its solution in diluted acids is lævorotatory.

Heat about 0.1 Gm. of powdered Cocaine with 1 cc. of sulphuric acid for five minutes at 100° C., then cautiously mix with 2 cc. of distilled water: the aromatic odor of methyl benzoate is noticeable and on cooling crystals of benzoic acid separate.

Tests for Purity—The ash from 0.5 Gm. is negligible.

Dissolve 0.1 Gm. of finely powdered Cocaine in 1 cc. of sulphuric acid: not more than a slightly yellow tint is produced (*readily carbonizable substances*).

Dissolve 0.3 Gm. of finely powdered Cocaine in 1 cc. of normal hydrochloric acid, gently warming, if necessary, to aid solution, and dilute with distilled water to 15 cc.: 5 cc. portions of this solution do not respond to the tests for *cinnamyl-cocaine* and for *isoatropyl-cocaine* under *Cocainæ Hydrochloridum*.

N. F. Preparation—Oleatum Cocainæ.

Uses—The alkaloid is required when a solution of cocaine in oil, liquid petrolatum, or fatty substances is prescribed, or in making a fatty ointment, otherwise cocaine hydrochloride is preferred. It is a cerebral stimulant and local anesthetic. Dose, one-fourth to one grain (0.015 to 0.06 Gm.). It can only be sold or dispensed under the rigid regulations of the Harrison Act (see Part VII).

COCAINÆ HYDROCHLORIDUM. U. S. Cocaine Hydrochloride

[**Cocain. Hydrochl.**—Cocaine Chloride, Cocainum Hydrochloricum P. I.]

The hydrochloride [$C_{17}H_{21}O_4N.HCl = 339.73$] of the alkaloid cocaine.

Preparation—It may be made by adding cocaine to an alcoholic solution of hydrochloric acid and crystallizing.

Description and Physical Properties—Colorless, transparent crystals, lustrous leaflets, or a white, crystalline powder. It is odorless and is stable in the air.

One Gm. of Cocaine Hydrochloride is soluble in 0.4 cc. of water, 3.2 cc. of alcohol, and in 12.5 cc. of chloroform, at 25° C. One Gm. is soluble in 2 cc. of alcohol at 60° C. It is soluble in glycerin and insoluble in ether.

Tests for Identity—Melting point not below 183° C.

Add five drops of a solution of chromium trioxide (1 in 20) to 5 cc. of a solution of Cocaine Hydrochloride (1 in 50): a yellow precipitate is produced which redissolves on shaking the mixture. On the addition of 1 cc. of hydrochloric acid, a permanent, orange-colored, crystalline precipitate is formed.

A solution of about 0.01 Gm. of Cocaine Hydrochloride in 1 cc. of distilled water yields on the addition of 2 cc. of tenth-normal potassium permanganate a violet, crystalline precipitate which appears brownish-violet when collected on a filter, and shows characteristic, crystalline aggregates under the low power of a microscope.

Heat about 0.1 Gm. of powdered Cocaine Hydrochloride with 1 cc. of sulphuric acid for five minutes then cautiously mix with 2 cc. of distilled water; the aromatic odor of methyl benzoate is noticeable and on cooling crystals of benzoic acid separate.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate insoluble in nitric acid.

Tests for Purity—The ash from 0.5 Gm. is negligible.

Dissolve 0.5 Gm. of Cocaine Hydrochloride in 1 cc. of sulphuric acid: not more than a slightly yellow tint is produced (*readily carbonizable substances*).

A solution of 0.5 Gm. of Cocaine Hydrochloride in 10 cc. of distilled water requires for neutralization not more than 0.5 cc. of fiftieth-normal sodium hydroxide, using one drop of methyl red T.S. as indicator.

Mix 5 cc. of an aqueous solution of the salt (1 in 50) with 0.3 cc. of normal sulphuric acid and 0.1 cc. of tenth-normal potassium permanganate: the violet color does not disappear entirely within a half hour (*cinnamyl-cocaine*).

Dilute 5 cc. of an aqueous solution of the salt (1 in 50) in a beaker with 80 cc. of distilled water, add 0.2 cc. of ammonia T.S., and stir the solution vigorously during five minutes, occasionally rubbing the sides of the beaker with a stirring rod; a crystalline precipitate of cocaine is formed and the supernatant liquid is clear (*isoatropyl-cocaine*). The presence of 0.5 per cent of isoatropyl-cocaine will prevent the formation of nearly all of the precipitate, and will cause the supernatant liquid to be milky.

Uses—Cocaine hydrochloride is used as a local anesthetic when applied to the mucous membrane or injected hypodermically; it is also a cerebral stimu-

lant. The dose is from one-fourth to one grain (0.015 to 0.06 Gm.). Because of the habit-forming character of this drug the sale of cocaine or cocaine hydrochloride is forbidden by the Harrison Act and most State laws, except upon physicians' prescriptions, and these must not be renewed, nor may they be filled for habitués. (For full details see Part VII.)

EUCAINÆ HYDROCHLORIDUM. U. S. Eucaine Hydrochloride

[**Eucain. Hydrochl.**—BETAEUCAINÆ HYDROCHLORIDUM U. S. P. IX]

Eucaine Hydrochloride, when dried to constant weight at 100° C., contains not less than 99 per cent of $C_5H_7N(CH_3)_3O(C_6H_5CO).HCl$ (283.72).

Preparation—Eucaine is a synthetic derivative of piperidine. It is prepared by treating diacetonamine with paraldehyde, reducing the product with metallic sodium to vinyl-di-acetone-alkamine and then treating this with benzoyl chloride to produce betaeucaine. This is afterwards neutralized with hydrochloric acid to produce the official salt. While this salt is similar to cocaine in its action as a local anesthetic, it is not related chemically and it is claimed that it is not habit-forming, and, according to a ruling, is not subject to the restrictions of the Harrison Act.

Description and Physical Properties—A white, odorless, crystalline powder. It is stable in the air.

One Gm. of Eucaine Hydrochloride is soluble in 30 cc. of water, 35 cc. of alcohol, and in 6 cc. of chloroform, at 25° C. It is more soluble in boiling water and in boiling alcohol.

Tests for Identity—Dissolve about 0.1 Gm. of the salt in 1 cc. of sulphuric acid. Keep the solution at 100° C. for five minutes, and then mix it cautiously with 2 cc. of water: the aromatic odor of methyl benzoate becomes noticeable and on cooling crystals of benzoic acid form.

Ten cc. portions of its saturated aqueous solution yield a white, curdy precipitate on the addition of mercuric chloride T.S., and a yellowish, curdy precipitate with a few drops of a mixture of equal volumes of potassium chromate T.S. and diluted sulphuric acid.

Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 100) a white precipitate which is insoluble in nitric acid.

Tests for Purity—An aqueous solution of Eucaine Hydrochloride (1 in 50) is neutral to litmus paper.

The ash from 0.5 Gm. is negligible.

A solution of 0.1 Gm. of Eucaine Hydrochloride in 1 cc. of sulphuric acid is colorless (*readily carbonizable substances*).

Triturate about 0.05 Gm. of the salt with about five times its weight of mild mercurous chloride and moisten the mixture with a few drops of water: no black color is produced (*difference from cocaine hydrochloride*).

No permanent precipitate is produced by the addition of 5 cc. of mercuric chloride T.S. to 5 cc. of an aqueous solution of the salt (1 in 100) (*cocaine and alphaeucaine*).

Assay—Dissolve about 0.5 Gm. of Eucaine Hydrochloride, previously dried to constant weight at 100° C. and accurately weighed, in 100 cc. of neutral alcohol. Titrate this alcoholic solution with tenth-normal sodium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of tenth-normal sodium hydroxide corresponds to 0.02837 Gm. of $C_5H_7N(CH_3)_3O(C_6H_5CO).HCl$.

This assay is explained on page 1453.

Uses—Eucaine Hydrochloride is a local anesthetic like cocaine, but weaker. It is used in ophthalmology in 2 to 3 per cent solutions; in 5 to 10 per cent solutions, for the nose and throat; in a 5 to 10 per cent ointment in the treatment of hemorrhoids. Other synthetic anesthetics, such as benzocaine, procaine, etc., will be found under benzoic acid derivatives, page 834.

CAFFEINA. U. S. Caffeine

[**Caff.**—THEINE]

Trimethyl-xanthine, a feebly basic substance [$C_8H_{10}O_2N_4+H_2O$ or $C_5H(CH_3)_3O_2N_4+H_2O=212.17$] obtained from the leaves of *Thea sinensis* Linné (Fam. *Ternstrœmiaceæ*), or from the seeds of *Coffea arabica* Linné (Fam. *Rubiaceæ*); also occurring in some other plants or prepared synthetically.

This alkaloid was discovered by Robiquet in coffee in 1821 while searching for quinine which he believed to be present. In 1827 Oudry found an alkaloid

in tea and called it *theine*. In 1838 Jobst and Mulder proved the identical character of the two principles.

Preparation—Caffeine occurs in the following per cent: in tea, 1 to 4.8; in kola nuts, 2.7 to 3.6; in coffee, 1 to 1.5; in maté, 1.25 to 2; in guarana, 3 to 5. Being a weak base, caffeine does not form stable salts and is often classed among the uric acid derivatives instead of the alkaloids. It is soluble in water in the presence of certain salts, as sodium salicylate or benzoate, and advantage is taken of this to form the several official compounds which follow.

Caffeine may be prepared from tea or coffee by precipitating a decoction with lead acetate, removing the excess of lead from the filtrate by hydrogen sulphide, adding ammonia water, evaporating, and recrystallizing. The source of the commercial supply is largely tea dust or sweepings. It may also be made synthetically by the further methylation of theobromine or theophylline, which are isomeric compounds chemically known as dimethylxanthine.

Description and Physical Properties—White, flexible, silky, glistening needles, usually matted together in fleecy masses. It is odorless, has a bitter taste, and is efflorescent in dry air.

One Gm. of Caffeine is soluble in 46 cc. of water, 66 cc. of alcohol, 50 cc. of acetone, 5.5 cc. of chloroform, 530 cc. of ether, and in 100 cc. of benzene, at 25° C. One Gm. is soluble in 5.5 cc. of water at 80° C., in 22 cc. of alcohol at 60° C., and in 22 cc. of boiling benzene.

Tests for Identity—Caffeine rendered anhydrous by drying at about 100° C. melts between 235° and 237° C.

A saturated aqueous solution of Caffeine is neutral to litmus paper.

Dissolve about 0.01 Gm. of Caffeine in 1 cc. of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate, and evaporate to dryness on a water bath. On inverting the dish over a vessel containing a few drops of ammonia T.S., the residue acquires a purple color which disappears upon the addition of solutions of fixed alkalies (*murexide reaction*)

A saturated aqueous solution of Caffeine yields with tannic acid T.S., a precipitate which is soluble in an excess of the reagent, but no precipitate is produced by tenth-normal iodine unless the solution is first acidulated with hydrochloric or sulphuric acid.

Tests for Purity—Caffeine loses not more than 9 per cent when dried to constant weight at 80° C.

Ash: not more than 0.05 per cent.

The solution of 0.5 Gm. of Caffeine in 5 cc. of sulphuric or nitric acid is colorless or only faintly yellow (*readily carbonizable substances*).

No precipitate is produced by mercuric potassium iodide T.S. in an aqueous solution of Caffeine (1 in 50) (*alkaloids*).

U. S. P. Preparations—Caffeina Citrata; Caffeinæ Sodio-Benzoas.

N. F. Preparations—Caffeinæ Sodio-Salicylas; Pulvis Acetanilidi Compositus; Sal Potassii Bromidi Effervescens Compositus.

Uses—Caffeine is a nerve stimulant. It is chiefly used in nervous headaches of a certain type. The dose is from one to three grains (0.06 to 0.2 Gm.).

CAFFEINA CITRATA. U.S. Citrated Caffeine

[Caff. Cit.]

Citrated Caffeine, when dried to constant weight at 80° C., contains not less than 48 per cent and not more than 52 per cent of anhydrous caffeine [$C_8H_{10}O_2N_4$ = 194.15].

The formula of the U. S. P. IX is as follows:

	Metric	Alternative
Caffeine	50 Gm.	1 oz. av.
Citric Acid	50 Gm.	1 oz. av.
Distilled Water, hot	100 cc.	2 fl. oz.

Dissolve the citric acid in the hot distilled water, add the caffeine, and evaporate the resulting solution to dryness on a water bath, constantly stirring toward the end of the operation. Reduce the product to a fine powder and transfer it to well-closed containers.

This is not a definite chemical salt, but a mixture of caffeine and citric acid. The common name *citrate of caffeine* is therefore improper.

Description and Physical Properties—A white, odorless powder, having a slightly bitter, acid taste.

One Gm. of Citrated Caffeine is soluble in about 4 cc. of warm water. On diluting the solution with an equal volume of water, a portion of the caffeine gradually separates, but redissolves on the further addition of water.

Tests for Identity—The residue obtained in the assay when recrystallized from hot water and dried to constant weight at 80° C. has the melting point given under *Caffeina*.

An aqueous solution of Citrated Caffeine (1 in 30) is acid to litmus paper.

Dissolve about 0.02 Gm. of Citrated Caffeine in 1 cc. of hydrochloric acid in a porcelain dish, add 0.1 Gm. of potassium chlorate, and evaporate to dryness on a water bath. On inverting the dish over a vessel, containing a few drops of ammonia T.S., the residue acquires a purple color, which disappears upon the addition of solutions of fixed alkalies (*murexide reaction*).

About 2 cc. of a filtered aqueous solution of Citrated Caffeine (1 in 10) mixed with 50 cc. of lime water remains clear in the cold but becomes turbid when heated to boiling. Add 1 cc. of mercuric sulphate T.S. to 5 cc. of an aqueous solution of Citrated Caffeine (1 in 100), heat the mixture to boiling, and add 1 cc. of potassium permanganate T.S.: a white precipitate is formed.

Tests for Purity—Dried to constant weight at 80° C., Citrated Caffeine loses not more than 5 per cent (*water*).

Ash: not more than 0.1 per cent.

Heat a mixture of 0.25 Gm. of Citrated Caffeine and 5 cc. of sulphuric acid in a porcelain dish on a water bath for fifteen minutes, protecting it from dust; it may become yellow but not brown or black (*tartrate*).

An aqueous solution of Citrated Caffeine meets the requirements of the test for *heavy metals*, page 1519.

The addition of a few drops of barium chloride T.S. to 10 cc. of an aqueous solution of Citrated Caffeine (1 in 100), previously treated with a few drops of hydrochloric acid, produces no turbidity (*sulphate*).

Assay for Caffeine—Dissolve about 0.5 Gm. of Citrated Caffeine, previously dried to constant weight at 80° C. and accurately weighed, in 10 cc. of hot distilled water, add 10 cc. of sodium hydroxide T.S., cool the solution, and shake it on a separator with three successive portions of 20 cc., 10 cc., and 5 cc., respectively, of chloroform, or more if necessary to complete the extraction. Evaporate the combined chloroform solutions on a water bath, dry the residue to constant weight at 80° C., and weigh.

Preserve in well-closed containers.

Uses—It is used as a cerebral stimulant in doses of three to eight grains (0.2 to 0.5 Gm.).

CAFFEINÆ SODIO-BENZOAS. U. S. Caffeine Sodio-Benzoate

[Caff. Sod. Benz.]

A mixture of caffeine and sodium benzoate, which contains, when dried to constant weight at 80° C., not less than 47 per cent and not more than 50 per cent of anhydrous caffeine [$C_8H_{10}O_2N_4 = 194.15$], and not less than 50 and not more than 53 per cent of sodium benzoate [$NaC_7H_5O_2 = 144.08$].

Preparation—It may be prepared by triturating together equal parts of caffeine and sodium benzoate, in a mortar, with enough alcohol to form a smooth paste, drying at a moderate heat, and powdering.

Description and Physical Properties—A white, odorless powder, having a slightly bitter taste.

One Gm. of Caffeine Sodio-Benzoate is soluble in 1.1 cc. of water, a portion of the caffeine usually separating on standing and in 30 cc. of alcohol, at 25° C. It is partly soluble in chloroform.

Tests for Identity—On heating, it is decomposed with the evolution of white vapors of caffeine, leaving a residue which effervesces with acids and colors a non-luminous flame intensely yellow.

Ferric chloride T.S. produces a salmon-colored precipitate, and diluted hydrochloric acid produces a white precipitate in an aqueous solution of Caffeine Sodio-Benzoate.

The residue obtained in the assay for caffeine when recrystallized from hot water, and dried to constant weight at 80° C., has the melting point of Caffeine, and responds to the other tests for identity under *Caffeina*.

Tests for Purity—Its aqueous solution (1 in 20) may be neutral, slightly acid, or slightly alkaline to litmus paper, but is not reddened by phenolphthalein T.S.

When dried to constant weight at 80° C., Caffeine Sodio-Benzoate loses not more than 5 per cent of its weight (*water*).

The solution of 0.1 Gm. of Caffeine Sodio-Benzoate in 2 cc. of sulphuric acid is colorless or only faintly yellow (*readily carbonizable substances*).

Dissolve about 2 Gm. of Caffeine Sodio-Benzoate in 40 cc. of distilled water in a separator, add 10 cc. of diluted sulphuric acid, extract the liberated benzoic acid with two successive 10 cc. portions of ether, and allow the ether solution to evaporate to dryness at room temperature: one-half Gm. of the benzoic acid so obtained complies with the test for *chlorinated compounds* under *Acidum Benzoicum*.

Its aqueous solution (1 in 50) acidulated with hydrochloric acid and filtered, meets the requirements of the test for *heavy metals*, page 1519.

Assay for Caffeine—Dissolve about 1 Gm. of Caffeine Sodio-Benzoate, previously dried to constant weight at 80° C. and accurately weighed, in 5 cc. of distilled water in a separator, add 5 cc. of sodium hydroxide T.S. and shake the mixture with four successive portions of 20 cc., 10 cc., 10 cc., and 5 cc., respectively, of chloroform. Pass the chloroform solutions through a filter which has been previously moistened with chloroform, and wash the stem of the funnel and filter with a few cc. of hot chloroform to remove any adhering caffeine. Evaporate the combined chloroform solutions on a water bath, and dry the residue, consisting of anhydrous caffeine, to constant weight at 80° C.

This assay is explained on page 1476.

Assay for Sodium Benzoate—To the aqueous liquid from which the caffeine has been removed in the above assay for caffeine, add 10 cc. of diluted sulphuric acid, and extract the liberated benzoic acid with four successive portions of 20 cc., 10 cc., 10 cc., and 5 cc., respectively, of chloroform. Pass the chloroform solutions through a filter which has been previously moistened with chloroform, and wash the stem of the funnel and the filter with a few cc. of hot chloroform. Evaporate the combined chloroform solutions to about 5 cc. at a temperature not exceeding 40° C., add 25 cc. of diluted alcohol previously neutralized with tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal barium hydroxide to the restoration of the pink color. Each cc. of tenth-normal barium hydroxide corresponds to 0.01441 Gm. of sodium benzoate ($NaC_7H_5O_2$).

This assay is explained on page 1456.

Uses—Its solubility renders it especially adaptable for the hypodermic injection of caffeine. It is a diuretic and cardiac stimulant. Dose, by the mouth, five grains (0.32 Gm.); hypodermically, three grains (0.2 Gm.).

CAFFEINÆ SODIO-SALICYLAS. N. F. Caffeine Sodio-Salicylate

[Caff. Sod.-Sal.]

	Metric	Alternative
Caffeine	**50 Gm.**	2 oz. av.
Sodium Salicylate	**50 Gm.**	2 oz. av.
Alcohol, a sufficient quantity,		
To make about	**100 Gm.**	4 oz. av.

Triturate the caffeine with the sodium salicylate and a sufficient quantity of alcohol to produce a smooth paste and dry this by exposure to air in a moderately warm place. Reduce the dry mass to powder and keep it in well-stoppered bottles.

Assay for Caffeine—Dissolve 1 Gm. of Caffeine Sodio-Salicylate, previously dried to constant weight at 80° C. and accurately weighed, in about 5 cc. of distilled water in a separator, add 5 cc. of sodium hydroxide T.S. and extract the caffeine with successive portions of chloroform until the chloroformic residue gives no test for alkaloid with iodine T.S. Evaporate the combined chloroform solutions to dryness on a water bath, moisten the residue with alcohol and again evaporate to dryness. Dry the residue to constant weight at 80° C. and weigh. The weight of anhydrous caffeine corresponds to not less than 46 per cent and not more than 50 per cent of the Caffeine Sodio-Salicylate taken.

This assay is explained on page 1476.

Uses—This compound has the same therapeutic activity as caffeine and has the advantage of being water soluble. The dose is three grains (0.2 Gm.).

Unofficial Preparation of Caffeine

Effervescent Citrated Caffeine, U. S. P. IX—It contains not less than 1.9 per cent of anhydrous caffeine.

Powder 195 Gm. [3 oz. av. 394 gr.] of citric acid and mix it intimately with 40 Gm. [350 gr.] of citrated caffeine and 300 Gm. [6 oz. av.] of tartaric acid, then thoroughly incorporate 570 Gm. [11 oz. av. 175 gr.] of sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. Manipulate the mixture carefully with a wooden spatula, and, when it has become moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. Immediately transfer the product to suitable containers and seal them tightly. Care must be used to prevent the preparation from coming in contact with air containing moisture.

Assay—Dissolve about 5 Gm. of Effervescent Citrated Caffeine, accurately weighed, in 10 cc. of hot distilled water. When effervescence has ceased, add an excess of sodium hydroxide T. S., cool the mixture and shake it in a separator with three successive portions of 20 cc., 10 cc., and 5 cc., respectively, of chloroform, or more if necessary to complete the extraction. Evaporate the combined chloroform solutions on a water bath and dry the residue to constant weight at 80° C. The weight of anhydrous caffeine, ($C_8H_{10}O_2N_4$) so obtained corresponds to not less than 1.9 per cent of the weight of Effervescent Citrated Caffeine taken. This residue, when recrystallized from hot water, responds to the tests for identity, and, when dried to constant weight at 80° C., has the melting point given under *Caffeina*.

Uses—This effervescent salt is used for preparing a pleasant stimulating draught by adding a teaspoonful (4 Gm.) to four fluidounces of water.

THEOPHYLLINA. U. S. Theophylline

[Theophyll.—Dimethylxanthine theocin]

An organic base, dimethylxanthine [$C_7H_8O_2N_4 + H_2O$ or $1:3\ C_5H_2(CH_3)_2.O_2N_4 + H_2O = 198.15$], isomeric with theobromine. It is found in small amounts in the leaves of *Thea sinensis* Linné (Fam. *Ternstræmiaceæ*) and is also prepared synthetically.

Preparation—This alkaloid is isomeric with theobromine and is found as a natural alkaloid in tea in small amounts, but it was made synthetically by a complicated process involving the methylation of uric acid and now more generally from carbamide or dimethyl carbamide. This is the first alkaloid to be made artificially on a commercial scale. It is similar in its chemical properties to caffeine and theobromine, and, with them, is often, classed with the derivatives of uric acid.

Description and Physical Properties—A white, crystalline, odorless powder having a bitter taste. It is stable in the air.

One Gm. of Theophylline is soluble in 120 cc. of water and in 80 cc. of alcohol, at 25° C. It is more readily soluble in hot water; sparingly soluble in ether. It is readily soluble in solutions of potassium hydroxide and in ammonia water.

Tests for Identity—Theophylline melts between 269° and 272° C.

To about 0.01 Gm. of Theophylline, contained in a porcelain dish, add 1 cc. of hydrochloric acid and 0.1 Gm. of potassium chlorate, and evaporate to dryness on a water bath: on inverting the dish over a vessel containing a few drops of ammonia T.S., the residue acquires a purple color which is destroyed by fixed alkalies.

An aqueous solution of Theophylline yields with tannic acid T.S. a precipitate which is soluble in an excesss of the reagent.

Tests for Purity—A saturated aqueous solution of Theophylline is neutral to litmus paper.

Theophylline loses not more than 9.5 per cent when dried to constant weight at 100° C. (*water*).

The ash from 0.1 Gm. is negligible.

Two-tenths Gm. of Theophylline dissolves in 5 cc. of sulphuric acid without producing more than a faint yellow color (*readily carbonizable substances*).

A clear solution is produced when 0.2 Gm. of Theophylline is dissolved in 5 cc. of potassium hydroxide T.S. or in 5 cc. of ammonia T.S. (*difference from caffeine, theobromine, or paraxanthine*).

Uses—It is used as a stimulating diuretic, similar to caffeine. Dose, four grains (0.25 Gm.).

THEOBROMINÆ SODIO-SALICYLAS. U. S. Theobromine Sodio-Salicylate

[Theobrom. Sodio-Sal.]

A mixture of sodium theobromine [$C_7H_7O_2N_4Na = 202.12$] and sodium salicylate [$NaC_7H_5O_3$] in approximately molecular proportions. It yields, when dried to constant weight at 110° C., not less than 46.5 per cent of theobromine [$C_7H_8O_2N_4 = 180.13$] and not less than 35 per cent of salicylic acid [$HC_7H_5O_3 = 138.08$].

Preparation—*Theobromine*, which is obtained from the seed of *Theobroma Cacao*, is said to be absent in the unfermented seeds, but is developed in the curing process, through the splitting up of a glucoside. It is also present in kola nuts and tea. It may be prepared by boiling the powdered beans with water, filtering, precipitating the tannins and coloring matter with lead acetate, removing the lead with sulphuric acid, filtering, concentrating, adding magnesia, evaporating to dryness, extracting the residue with alcohol, and purifying the product by recrystallization. Theobromine has been also synthesized from methylcarbamide. Theobromine is a uric acid derivative and is often so classed instead of under alkaloids.

The official salt, commonly known as *diuretin*, is made by preparing an alcoholic solution of sodium hydroxide, adding an amount equal to 20 parts of the hydroxide to 100 parts of water and 90 parts of theobromine, and warming the mixture until solution results. This is then added to 80 parts of sodium

salicylate in 75 parts of water and the solution quickly evaporated to dryness and powdered.

Description and Physical Properties—A white, odorless powder, having a sweetish, saline and somewhat alkaline taste. It gradually absorbs carbon dioxide from the air with the liberation of theobromine, becoming incompletely soluble in water. It also frequently develops a characteristic odor.

One Gm. of Theobromine Sodio-Salicylate is soluble in 1 cc. of water at 25° C. It is slightly soluble in alcohol.

Tests for Identity and Purity—(See U. S. P. X.).

Assay for Theobromine—(See U. S. P. X.). This assay is explained on page 1477.

Assay for Salicylic Acid—(See U S. P. X.). This assay is explained on page 1456.

Preserve in well-closed containers.

Uses—It is used as a diuretic in cardiac dropsy and chronic Bright's disease. The dose is fifteen grains (1 Gm.).

Unofficial Theobromine and Theobromine Compounds

Theobromine—Theobromina, N. N. R.—3.7-Dimethyl-Xanthine—$C_5H_2(CH_3)_2.O_2N_4$. A base occurring in *Theobroma cacao;* also made synthetically.

Colorless, rhombic needles or a white crystalline powder, odorless, bitter, and permanent in the air. Theobromine is slightly soluble in water, alcohol, ethyl acetate and chloroform, and insoluble in petroleum ether. It is soluble in aqueous solutions of the alkalis.

Uses—The uses of theobromine are similar to those of caffeine, but its action is said to be relatively greater on the heart and muscles and also as a diuretic. It does not act so powerfully on the central nervous system.

It is used as a diuretic. The great obstacle to its use has been its insolubility and the consequent uncertainty of the degree of its absorption. It is liable to produce gastric disturbances.

Dose—From 5 to 8 grains (0.35 to 0.5 Gm.).

Theobromine Sodium Acetate—Theobrominæ Sodio-Acetas, N. N. R.—A hydrated double salt of theobromine-sodium and sodium acetate, containing not less than 63 per cent of theobromine, corresponding to about 80 per cent of the anhydrous double salt—$NaC_7H_7O_2N_4+NaC_2H_3O_2$.

A white, finely crystalline powder, odorless and bitter. It is soluble in cold water; slightly soluble in cold alcohol; more so in hot alcohol. Its aqueous solutions are strongly alkaline toward phenolphthalein and litmus. It is quite hygroscopic, and in aqueous solution when exposed to air it gradually splits up into its components through absorption of carbon dioxide and becomes incompletely soluble.

Uses—Theobromine sodium acetate acts like theobromine, over which it has the advantages of greater solubility and of being well tolerated by the stomach. While inferior in diuretic power to theophylline (page 1154), it is said to have greater power in sustaining the diuresis produced.

Dose—From 8 to 15 grains (0.5 to 1 Gm.), preferably in wafers or capsules. If in solution, this should be freshly prepared (with peppermint water), without sugar or mucilage.

Agurin—A brand of the theobromine sodium acetate, distributed by the Winthrop Chemical Company.

Theobromine and Sodium Acetate is also manufactured by the Powers-Weightman-Rosengarten Company, and Hoffman-LaRoche Chemical Works.

Theocalcin N. N. R.—A double salt or mixture of calcium theobromine $([C_7H_7O_2N_4]_2Ca)$ and calcium salicylate $([C_7H_5O_3]_2Ca)$. It contains not less than 44 per cent of theobromine.

A white, amorphous powder having a saline taste. It is partly soluble in water.

Uses—Theocalcin acts like theobromine. It is claimed to be less likely to produce gastric irritation than the official theobromine sodio-salicylate.

Dose—Average dose, from 7 to 15 grains (0.5 to 1 Gm.), three times a day.

Manufactured by E. Bilhuber, Incorporated.

Unofficial Theophyllin Compounds

Theophyllin Sodio-Acetate—Theophyllinæ Sodio-Acetas, N. N. R.—$NaC_7H_7O_2N_4+NaC_2H_3O_2+H_2O$.—A double salt of sodium acetate and 1.3-dimethylxanthine-sodium (theophyllinsodium).

A white crystalline powder, containing about 60 per cent of anhydrous theophyllin. It dissolves in about 20 parts of water at 25° C., but is insoluble in alcohol or ether.

Dose—From 3 to 5 grains (0.2 to 0.35 Gm.), best given after meals.

Theocin Sodium Acetate—A brand of theophyllin sodio-acetate, distributed by the Winthrop Chemical Company.

LOBELIA. U. S. Lobelia

[**Lobel.**—INDIAN TOBACCO]

Lobelia consists of the dried leaves and tops of *Lobelia inflata* Linné (Fam. *Lobeliaceæ*).

Lobelia contains not more than 10 per cent of stems or more than 2 per cent of other foreign organic matter, and yields not more than 5 per cent of acid-insoluble ash.

Description—Leaves alternate, sessile or narrowing into a short petiole, usually more or less broken; when entire, blades ovate or oblong, from 2 to 9 cm. in length, obtusely toothed or irregularly serrate-denticulate, each tooth with a yellow-brown, gland-like apex; pale green and with

scattered bristly hairs; stem cylindrical, coarsely and irregularly furrowed, yellowish-green, occasionally purplish and with numerous spreading hairs; flowers pale blue, in a long, loose raceme with short pedicels, calyx tubes ovoid, with 2 subulate teeth, corollas tubular, from 3 to 4 mm. in length, 5-parted, the upper 2-lobed portion cleft nearly to the base; stamens with anthers united above into a curved tube enclosing the bifid stigma; capsule ovoid or ellipsoidal, from 5 to 8 mm. in length, light brown, wholly inferior and enclosing numerous brownish, oblong and coarsely reticulate seeds; odor slight and irritating; taste strongly acrid.

For further description see the U. S. P. X.

U. S. P. Preparation—Tinctura Lobeliæ.

Lobelia contains *lobeline*, $C_{23}H_{29}O_2N_2$, *lobelic acid*, *lobelacrin*, *inflatin*, and *lobelianin*, a volatile oil, wax, resin, gum, etc. Lobeline at one time was believed to be a liquid alkaloid but recent work has demonstrated its crystalline form. It melts at 130° C. and has an $[a]_D$ of -42.8, in alcohol. Lobeline is a violent emetic.

Uses—Lobelia is used as an expectorant in 2 grain (0.125 Gm.) doses or as an emetic in 40 grain (2.6 Gm.) doses.

Average dose—1½ grains (0.1 Gm.).

BAPTISIA. N. F. Baptisia

[**Baptis.**—Wild Indigo]

Baptisia is the dried root of *Baptisia tinctoria* (Linné) R. Brown (Fam. *Leguminosæ*). Baptisia contains not more than 10 per cent of its stem bases, over-ground parts, or more than 2 per cent of other foreign organic matter.

It contains *cytisine* or *baptitoxine*, which is found in several other plants, also several other glucosides: *baptisin*, *baptigenin*, *pseudobaptisin*, and *baptin*, also resin. Cytisine melts at 153° C. and has an $[a]_D$ of -119 in water at 17° C. It is soluble in water, alcohol, or in chloroform, and insoluble in ether.

Description—Fleshy, from 0.5 to 4 cm. in thickness, usually cut into elongated cylindrical pieces; the crown from 5 to 8 cm. in thickness, more or less warty and marked by stem scars; outer surface dark brown; usually longitudinally wrinkled, the thicker pieces covered with a soft and friable corky layer bearing few branching rootlets; fracture tough, the fractured surface whitish; bark-section radially striate, wood-section inconspicuously radiate, porous. Nearly odorless; the bark bitter and acrid, the wood nearly tasteless.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Baptisiæ.

Uses—It is a cathartic and hepatic stimulant, also employed as a nerve stimulant and antipyretic. It is also used in pharmacy to produce a yellow color in such preparations as the antiseptic solutions. Dose, fifteen grains (1 Gm.).

BERBERIS. N. F. Berberis

[**Berber.**—Oregon Grape Root]

Berberis consists of the dried rhizome and roots of species of the section *Mahonia* (Nuttall) De Candolle of the genus *Berberis* Linné (Fam. *Berberidaceæ*).

Berberis contains not more than 5 per cent of the overground parts of the plant or other foreign organic matter. Reject pieces of the rhizome or root over 45 mm. in diameter or with the bark removed.

Berberis contains a yellow alkaloid, *berberine*, $C_{20}H_{17}O_4N$, and *oxyacanthine* (*berbine* or *vinetine*), $C_{18}H_{19}O_3N$, and *berbamine*, $C_{18}H_{19}O_3N$.

Description—Cylindrical more or less knotty, strongly branched, usually cut into pieces of varying length and up to 45 mm. in diameter; usually splitting somewhat on drying; externally light yellowish-brown, longitudinally wrinkled and short, scaly; fracture hard and tough; bark 1 mm. in thickness, easily separable into layers; wood yellow, the color more pronounced upon wetting, distinctly radiate, and showing rings of growth; pith of rhizome small, sometimes excentral. Odor slight; taste distinctive, very bitter; on chewing it tinges the saliva yellow.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Berberidis.

Uses—It is used as a tonic, hepatic stimulant, antiperiodic, and febrifuge. Dose, thirty grains (2 Gm.).

CACTUS GRANDIFLORUS. N. F. Cactus Grandiflorus

[Cact. Grand.—Night Blooming Cereus]

Cactus Grandiflorus is the fresh succulent stem of the wild growing *Selenicereus grandiflorus* (Linné) Britton et Rose (Fam. *Cactaceæ*).

As found in commerce, Cactus Grandiflorus is usually preserved in alcohol and the amount of alcohol present should be stated on the label.

Its constituents have not been well studied; it contains a small amount of alkaloid, glucosidal bodies, acid, fat, etc. The preserved fresh stems only are recognized by the N. F., never the dried plant.

Description—In pieces of varying length, from 1.5 to 4 cm. in diameter, and from five- to nine-angled. The angles at intervals of about 2 cm. with tufts of from nine to twelve acicular spines about 5 mm. in length together with about the same number of bristles about 1 cm. in length; at irregular intervals branched roots are sometimes present; a strong, herby odor; taste acidulous and mucilaginous.

For further description see the N. F. V.

N. F. Preparation—Tinctura Cacti Grandiflori.

Uses—It is employed as a substitute for digitalis in cardiac weakness. The dose of the tincture is fifteen minims (1 cc.).

COCCULUS. N. F. Cocculus

[Fish Berry, Indian Berry]

Cocculus is the dried ripe fruit of *Anamirta Cocculus* (Linné) Wight et Arnott (Fam. *Menispermaceæ*).

Cocculus contains not more than 2 per cent of foreign organic matter.

It contains the alkaloids *menispermine*, $C_{18}H_{24}O_2N_2$, and *paramenispermine*, and *hydropicrotoxic acid*, also *picrotoxin*, the poisonous principle.

Description—Reniform, 8 to 13.5 mm. in length and 7 to 11 mm. in breadth and 7 to 10 mm. in thickness, blackish-brown or reddish-brown, wrinkled; hilum and micropyle close together, separated by a shallow sinus and connected by an obscure ridge running around the convex side; distinct circular stalk-scar. Pericarp tough, about 1 mm. thick, outer layer brownish, inner layer light yellow, enclosing a single seed. Seed whitish-yellow, urn-shaped, its longitudinal and transverse sections crescent-shaped. Taste slightly bitter; the seed intensely bitter.

For further description see the N. F. V.

N. F. Preparation—Tinctura Cocculi.

Uses—The tincture is used externally as a parasiticide.

COFFEA TOSTA. N. F. Coffee

[Coff. Tost.—Roasted Coffee]

Coffee is the dried ripe seed of *Coffea arabica* Linné or *Coffea liberica* Bulliard (Fam. *Rubiaceæ*), deprived of most of the seed coat and roasted until a dark brown color and a characteristic aroma are developed.

Coffee yields not less than 1 per cent of caffeine, not less than 3 per cent and not more than 5 per cent of total ash and not less than 10 per cent of fat.

Its chief constituent is *caffeine*, although it contains tannic acid and *caffeic* and *quinic acids*.

Description—Oval, of variable size, having one side strongly convex, the other flat with a longitudinal groove, and showing traces of the papery seed coat in the cleft. It has a characteristic aroma and a pleasantly bitter taste.

For further description see N. F. V.

Assay—Place 6 Gm. of Coffee, in fine powder, in a suitable flask or bottle, add 120 cc. of chloroform and shake. Allow to stand five minutes, then add 6 cc. of ammonia water and shake the mixture continuously during one hour, or intermittently (see Proximate Assays, Type Process A, page 1494), during two hours. Allow the mixture to stand overnight, again shake intermittently during one-half hour, then allow the drug to settle. Decant, or filter off through a pledget of purified cotton, 100 cc. of the chloroformic liquid, representing 5 Gm. of Coffee, and evaporate it to dryness. Treat the residue with 10 cc. of weak (about 1 per cent) sulphuric acid with the aid of a gentle heat, allow to cool, filter through a small filter into a separator, and wash the dish and filter with successive small portions of distilled water until no test for alkaloid is obtained by acidulating a few drops of the filtrate strongly with sulphuric acid and adding iodine T.S. Now add ammonia water until the liquid is distinctly alkaline to litmus, and completely extract the caffeine with successive portions of chloroform, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions, and dry the residue at 80° C. to constant weight. The weight is the amount of caffeine from 5 Gm. of Coffee.

This assay is explained on page 1500.

N. F. Preparation—Fluidextractum Coffeæ.

Uses—It is chiefly used for its flavor and stimulating effects.

CONIUM. N. F. Conium

[Poison Hemlock]

Conium consists of the dried full grown, but unripe fruit of *Conium maculatum* Linné (Fam. *Umbelliferæ*).

Conium contains not more than 2 per cent of foreign fruits, seeds, or other foreign organic matter and yields not less than 0.5 per cent of coniine. After being kept for more than two years, it is unfit for use. Conium should be carefully dried and preserved.

Description—Broadly ovoid, greenish-gray, the two mericarps often separated, each about 3 mm. in length and about 1.5 mm. in diameter, ovoid, somewhat curved, the inner flattened side marked by a deep longitudinal groove, the outer, convex side with five, pale yellow, somewhat crenate ribs, the intervening surfaces wrinkled, pericarp without oil tubes. Odor slight, but when triturated with a solution of potassium hydroxide, strong, disagreeable, and mouse-like; taste characteristic, disagreeable, afterwards somewhat acrid.

For further test see the N. F. V.

Assay—Place 15 Gm. of Conium, in a moderately fine powder, in a 250 cc. flask or bottle, add 150 cc. of purified petroleum benzin, allow to stand five minutes, then add 15 cc. of solution of sodium hydroxide U. S. P., stopper securely and shake the flask vigorously at intervals during two hours. Allow it to stand overnight and again agitate vigorously at intervals during one hour. Allow the mixture to settle, decant 100 cc. of the clear fluid (representing 10 Gm. of Conium) and extract the alkaloids from this by shaking out this with successive portions of weak hydrochloric acid, until a few drops of the acid washings give no test for alkaloid with iodine T.S. Evaporate the combined acid washings on a water bath to a volume of about 10 cc., cool, and transfer to a separator and render it alkaline by the cautious addition of sodium carbonate. Extract the alkaline liquid with successive small portions of purified petroleum benzin, until it gives no test for alkaloid with iodine T.S., and to the combined benzin washings add 10 cc. of tenth-normal sulphuric acid. Stir thoroughly during two minutes, to bring the acid in contact with the benzin solution, then evaporate the benzin layer in a current of warm air. Titrate the acid solution, using cochineal T.S. or methyl red T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.0126 Gm. of coniine.

This assay is explained on page 1500.

N. F. Preparation—Extractum Conii.

Conium contains *coniine*, $C_8H_{17}N$, *conhydrine* or *oxyconiine*, $C_8H_{17}ON$, and *pseudoconhydrine*, *ethyl-piperidine*, and *methylconiine*, $C_8H_{16}CH_3N$; also a little volatile oil and fixed oil. Coniine is a liquid volatile alkaloid, and contains no oxygen. It was the first alkaloid to be made by synthesis. Its odor resembles that of the urine of mice. It is soluble in water, alcohol, and ether.

Uses—Conium is used as a narcotic and sedative. Dose, three grains (0.2 Gm.).

COPTIS. N. F. Coptis

[Goldthread]

Coptis is the dried plant of *Coptis trifolia* (Linné) Salisbury (Fam. *Ranunculaceæ*).

Coptis contains not more than 3 per cent of foreign organic matter.

It contains the yellow alkaloid *berberine* and a white alkaloid called *coptine*.

Description—In loose, matted masses consisting of long, much-branched rhizomes and small roots, together with the leaves. Rhizomes orange or golden-yellow; leaves evergreen, long and slenderly petioled, trifoliate, the segments broadly obovate-cuneate, crenately lobed and toothed with sharp-pointed teeth, prominently veined, smooth, coriaceous, dark green and shining but often drying to a dull brownish hue; flowers, if present, small, solitary, terminating slender scapes; sepals five to seven, oblong, obtuse, deciduous; petals five to six, pale yellow, small club-shaped stamens numerous. Odor faint; taste purely bitter without astringency.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Coptis.

Uses—It is used as a tonic and in mouth-washes for canker-sores and as a gargle for sore throat. Dose, thirty grains (2 Gm.).

CORYDALIS. N. F. Corydalis

[Corydal.—Turkey Corn, Squirrel Corn]

Corydalis consists of the dried tubers of *Dicentra canadensis* (Goldie) Walp or *Dicentra Cucullaria* (Linné) Bernh (Fam. *Fumariaceæ*).

Corydalis contains not more than 3 per cent of foreign organic matter. It contains *corydaline*, $C_{22}H_{27}O_4N$, *fumaric acid*, bitter extractive, and acid resin.

Description—The tubers are spheroidal and frequently vertically depressed, the flattened surface more or less concave, up to 15 mm. in diameter; usually single, rarely two or more in a cluster; externally, minutely pitted or nearly smooth; grayish-brown, grayish-black, or amber-colored and more or less translucent; one of the flattened surfaces with a triangular scar from detached roots, the other usually with remains of the slender rhizome; fracture hard and horny, exhibiting a yellowish, waxy interior, or somewhat tough and granular, exhibiting a yellowish-white interior.

The grains of the granulate bulb of *Bicuculla Cucullaria* are ovoid or triangular-ovoid and up to 12 mm. in length; the larger grains distinctly concave on one surface, with a scar at the apex from the detached petiole, and usually attached to the short root-stock in clusters of three; the smaller grains usually separated from the root-stock, with an acute apex and a scar at the base; externally, yellowish- or grayish-brown, usually translucent; fracture hard and horny, exhibiting a grayish, waxy interior, or granular and tough, exhibiting a whitish interior. Nearly odorless; taste slightly bitter.

For further description see the N. F. V.

N. F. Preparations—Elixir Corydalis Compositum (from Fluidextract); Fluidextractum Corydalis; Fluidextractum Stillingiæ Compositum.

Uses—It is used as a tonic and antisyphilitic. Dose, ten grains (0.6 Gm.).

DELPHINIUM. N.F. Larkspur Seed

[**Delphin.**]

Larkspur seed is the dried ripe seed of *Delphinium Ajacis* Linné (Fam. *Ranunculaceæ*).

Larkspur seed contains not more than 2 per cent of foreign seeds or other foreign organic matter.

Delphinium Ajacis contains *ajacine*, $C_{15}H_{21}O_4N.H_2O$, and *ajaconine*, $C_{17}H_{29}O_2N$. *Delphinium Consolida* contains three unnamed alkaloids.

Description—Irregularly tetrahedral, or somewhat triangulate, acute at one end, obtuse or rounded at the other, about 2 mm. in length and equally broad or slightly narrower; surface black or blackish-brown, occasionally grayish with from 8 to 12 rows of centrifugally elongated epidermal cells transversely encircling the seed and forming wavy continuous vertical walls or ruffles occasionally intersecting and with narrow channels between; seed coat crustaceous; endosperm whitish, flashy and oily; embryo small, in flashy endosperm. Odor very faint; taste bitter, afterward biting and acrid.

For further description see the N. F. V.

N. F. Preparation—Tinctura Delphinii.

Uses—It is used almost entirely for the destruction of lice and the itch-mite. It may be employed as an ointment or as a lotion (see page 299), or in the form of the official tincture (see page 388).

DULCAMARA. N.F. Bittersweet

[**Dulcam.**]

Dulcamara is the dried stem of *Solanum Dulcamara* Linné (Fam. *Solanaceæ*).

Dulcamara contains not more than 2 per cent of foreign organic matter. It contains the alkaloids *solanine*, *solanidine*, and *solaneine*.

Description—In short sections about 5 mm. or less in thickness, cylindraceous, outline of transverse section somewhat angular, longitudinally striate, more or less warty, usually hollow in the center; bark thin, externally pale greenish, or light greenish-brown, glabrous, marked with alternate leaf scars, internally green, the greenish or yellowish wood occurring in one or two concentric rings. Odor slight; taste bitter, afterwards sweet.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Dulcamaræ.

Uses—It is used as a diuretic and sedative. Dose, one drachm (4 Gm.).

GELSEMIUM. N.F. Gelsemium

[**Gelsem.**—Yellow Jasmine Root, Yellow Jessamine]

Gelsemium consists of the dried rhizome and roots of *Gelsemium sempervirens* (Linné) Persoon (Fam. *Loganiaceæ*).

Gelsemium contains not more than 2 per cent of foreign organic matter.

Description—Rhizome cylindrical, usually in pieces from 3 to 20 cm. in length and from 3 to 30 mm. in diameter; externally light yellowish-brown, longitudinally wrinkled with purplish-brown longitudinal lines and transverse fissures; the upper surface with a few stem scars, the

under and side portions with numerous roots and root scars; fracture tough, splintery; internally light brown or pale yellow, bark thin, wood distinctly radiate, excentral, pith disintegrated; roots light brown; fracture one-half transverse, the other oblique or splintery. Odor slight, taste bitter.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Gelsemii; Elixir Sodii Salicylatis Compositum (from Fluidextract); Tinctura Gelsemii.

Gelsemium contains *gelsemine*, $C_{20}H_{22}O_2N_4$, a crystallizable alkaloid melting at 178° C. It has an $[\alpha]_D$ of +15.9. It also contains two amorphous alkaloids one of which is probably *gelseminine*. The activity of the drug seems to be due primarily to the amorphous alkaloids. It also contains volatile oil, starch, resin, fat, coloring matter, etc.

Uses—It is used as an antispasmodic and sedative. Dose, one and one-half grains (0.1 Gm.).

GUARANA. N. F. Guarana

(U. S. P. IX)

Guarana is a dried paste consisting chiefly of the crushed seed of *Paullinia Cupana* Kunth (Fam. *Sapindaceæ*).

Guarana yields not less than 4 per cent of caffeine.

Description—Usually in cylindrical sticks, about 3 to 5 cm. in diameter, externally dark reddish-brown; hard and heavy; fracture uneven, often fissured in the center; internally pale reddish-brown, showing more or less coarse fragments of seed and occasionally their blackish-brown integuments. Odor slight; taste slightly astringent and bitter.

For further description see the N. F. V.

Assay—Place 6 Gm. of Guarana, in fine powder, in a suitable flask or bottle, add 120 cc. of chloroform and shake. Allow to stand five minutes, then add 6 cc. of ammonia water and shake the mixture continuously during one hour, or intermittently (see Proximate Assays, Type Process A, page 1494) during two hours. Allow the mixture to stand overnight, again shake intermittently during one-half hour, then allow the drug to settle. Decant, or filter off through a pledget of purified cotton, 100 cc. of the chloroformic liquid, representing 5 Gm. of Guarana, and evaporate it to dryness. Treat the residue with 10 cc. of weak (about 1 per cent) sulphuric acid with the aid of a gentle heat, allow to cool, filter through a small filter into a separator, and wash the dish and filter with successive small portions of distilled water until no test for alkaloid is obtained by acidulating a few drops of the filtrate strongly with sulphuric acid and adding iodine T.S. Now add ammonia water until the liquid is distinctly alkaline to litmus, and completely extract the caffeine with successive portions of chloroform, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions, and dry the residue at 80° C. to constant weight. The weight is the amount of caffeine from 5 Gm. of Guarana.

This assay is explained on page 1501.

N. F. Preparations—Fluidextractum Guaranæ; Elixir Guaranæ (from Fluidextract).

Guarana contains *caffeine*, $C_8H_{10}N_4O_2$, to the extent of from 3 to 5 per cent and about 25 per cent of tannin, with resin, mucilage, starch, volatile oil, saponin, etc.

Uses—It is used as a nerve stimulant, in doses of thirty to sixty grains (2 to 4 Gm.). It is effective only in comparatively large doses.

IGNATIA. N. F. Ignatia

[Ignat.—Saint Ignatius Bean, Ignatia Amara]

Ignatia is the dried ripe seed of *Strychnos Ignatii* Bergius (Fam. *Loganiaceæ*).

Ignatia contains not less than 2 per cent of the alkaloids of Ignatia and not more than 1 per cent of foreign organic matter. Its constituents are similar to those from nux vomica, although the alkaloids are usually present in smaller amounts.

Description—Heavy, hard, angularly ovate with obtuse angles, from 20 to 30 mm. in length, and about 15 mm. in breadth and thickness; externally grayish or reddish-black, nearly smooth with few or no hairs; fracture granular and translucent in small fragments; a small, irregular cavity in the center. Nearly inodorous and intensely bitter.

For further description see the N. F. V.

Assay—Place 10 Gm. of Ignatia, in fine powder, in a 250 cc. bottle, add 100 cc. of ether-chloroform mixture, and proceed by Type Process A (page 1494). Decant 50 cc. of the ethereal solution to complete the assay, using chloroform as the immiscible solvent in shaking out the alkaline liquid, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.0364 Gm. of the alkaloids of Ignatia.

This assay is explained on page 1501.

N. F. Preparations—Extractum Ignatiæ; Tinctura Ignatiæ.

Uses—Similar to nux vomica. Dose, one grain (0.06 Gm.).

KOLA. N. F. Kola

[Kol.—Cola]

Kola is the dried cotyledon of *Cola nitada* (Ventenat) Schott and Endlicher, or of other species of *Cola* (Fam. *Sterculiaceæ*).

Kola yields not less than 1 per cent of caffeine and contains not more than 1 per cent of foreign organic matter. The chief constituent is *caffeine*, with small amounts of *theobromine*. It also contains *kolatin*, *kolanin*, tannic acid, fat, volatile oil, etc.

Description—Irregularly plano-convex, broadly oval, or approaching circular in outline, from 2.5 to 5 cm. in length, or triquetrous; heavy, hard, and tough; brown, with the outer surfaces slightly wrinkled, the inner surfaces lighter and smoother; edges slightly incurved and sharp. Odorless; taste slightly astringent.

For further description see the N. F. V.

Assay—Place 6 Gm. of Kola, in fine powder, in a suitable flask or bottle, add 120 cc. of chloroform and shake. Allow to stand five minutes, then add 6 cc. of ammonia water and shake the mixture continuously during one hour, or intermittently (see Proximate Assays, Type Process A, page 1494) during two hours. Allow the mixture to stand overnight, again shake intermittently during one-half hour, then allow the drug to settle. Decant, or filter off through a pledget of purified cotton 100 cc. of the chloroformic liquid, representing 5 Gm. of Kola and evaporate it to dryness. Treat the residue with 10 cc. of weak (about 1 per cent) sulphuric acid with the aid of a gentle heat, allow to cool, filter through a small filter into a separator, and wash the dish and filter with successive small portions of distilled water until no test for alkaloid is obtained by acidulating a few drops of the filtrate with sulphuric acid and adding iodine T.S. Now add ammonia water until the liquid is distinctly alkaline to litmus and completely extract the caffeine with successive portions of chloroform, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions, and dry the residue at 80° C. to constant weight. The weight is the amount of caffeine from 5 Gm. of Kola.

This assay is explained on page 1501.

N. F. Preparation—Fluidextractum Kolæ.

Uses—It is employed for the same purposes as caffeine. It is also used in cardiac weakness and tropical diarrhea. Dose, one drachm (4 Gm.).

MANACA. N. F. Manaca

[Manac.—Vegetable Mercury]

Manaca is the dried root of *Brunfelsia Hopeana* Bentham (*Franciscea uniflora* Pohl) (Fam. *Solanaceæ*).

The alkaloid *manacine* is claimed to be present and also a fluorescent compound said to be identical with gelsemic acid. It also contains fat, resin, and starch. Manacine is amorphous, slightly bitter and feebly basic and is soluble in water and alcohol. Some investigators doubt the presence of an alkaloid.

Description and Physical Properties—Nearly cylindrical or more or less tortuous, of variable length and up to about 3 cm. in diameter; externally dark brown, wrinkled and with scaly yellowish cork patches, the latter being easily removed from the thin cortex which adheres closely to the wood; inner surface bark thin, wood light yellowish, hard and finely radiate; fracture short and very tough; taste bitter; odor slight.

For further description see the N. F. V.

N. F. Preparations—Elixir Manacæ Compositum; Fluidextractum Manacæ.

Uses—It is employed in the treatment of muscular rheumatism in doses of fifteen grains (1 Gm.).

PAREIRA. N. F. Pareira

[Pareir.—Pareira Brava]

Pareira is the dried root of *Chondodendron tomentosum* Ruiz et Pavon (Fam. *Menispermaceæ*).

Pareira contains not more than 5 per cent of its stems or more than 2 per cent of other foreign organic matter. This root contains an alkaloid usually called *Pelosine*, $C_{18}H_{21}O_3N$; it also contains starch, gum, tannin, and *phlobaphene*. Pelosine has been proved to be identical with *buxine* and *bebeerine*, alkaloids obtained from *Buxus sempervirens* and *Nectandra Rodiæi*. The root is said to contain five alkaloids.

Description—Nearly cylindrical, more or less tortuous, of variable length and from 1 to 6 cm. in diameter; externally brownish-black or blackish-brown with transverse ridges on knot-like projections, occasionally fissured and longitudinally wrinkled or even furrowed; hard, heavy, and tough; when freshly cut having a waxy luster; the transverse surfaces exhibiting several suc-

cessive excentric and distinctly radiate concentric zones of projecting, secondary fibrovascular bundles each from 2 to 4 mm. in width, and separated by distinct concentric zones of parenchyma and stone cells, the zones radially marked by prominent medullary rays. Stems deeply furrowed, grayish in color, usually covered with foliaceous patches of lichens bearing their blackish apothecia; internally grayish-yellow, with a prominent development of wood with a tendency to separate fibrovascular bundles and without a waxy luster. Odor slight; taste very bitter.

N. F. Preparation—Fluidextractum Pareiræ.

Uses—Pareira is used as a tonic, diuretic, and aperient. The dose is thirty grains (2 Gm.).

PASSIFLORA. N. F. Passion Flower

[**Passiflor.**—PASSION VINE]

Passion Flower is the dried flowering and fruiting top of *Passiflora incarnata* Linné (Fam. *Passifloraceæ*).

Passion Flower contains not more than 5 per cent of stems over 8 mm. in diameter or other foreign matter. An alkaloid has been reported, but the constituents have not been carefully studied.

Description—Stems glabrous or slightly pubescent above, striate, from 6 to 8 mm. in diameter, of variable length, woody, hollow, the cavity about one-half the diameter; bark very thin, greenish or purplish; wood very porous and bordered on the inner side by a thin layer of pith; fracture of the wood uneven, of the stem smooth, or the bark coarsely fibrous. Leaves more or less broken, either thick, glabrous or often pubescent, when entire nearly orbicular in outline, base cordate, deeply three- to five-lobed, lobes ovate, acute, finely serrate, petioles from 1 to 5 cm. in length, with two glands near the summit. Tendrils numerous and closely coiled. Flowers solitary, axillary, peduncles as long as the petioles, usually three-bracted, calyx cup-shaped, four to five lobes; lobes linear, imbricated, cuspidate, corona of the fresh flowers purplish; petals four to five, yellow; ovary oblong, stalked; stamens monadelphous in a tube about the stalk of the ovary, separated above, anthers narrow, versatile. Fruit from 4 to 5 cm. in length, an ovoid many-seeded berry; externally green or yellow, shriveled and wrinkled; seeds flat, ovate, yellowish to brown, arilled. Taste and odor slight.

For further description see the N. F. V.

Test for Identity and Purity—Passion flowers yield not more than 12 per cent of ash.

N. F. Preparation—Tinctura Passifloræ.

Uses—It has been used as an application in hemorrhoids, erysipelas, and burns; also internally in neuralgia. It is not often used today. Dose, three grains (0.2 Gm.).

SANGUINARIA. N. F. Sanguinaria

(U. S. P. IX)

[**Sanguin.**—BLOOD ROOT]

Sanguinaria consists of the dried rhizome and roots of *Sanguinaria canadensis* Linné (Fam. *Papaveraceæ*).

Sanguinaria contains not more than 2 per cent of foreign organic matter.

Sanguinaria contains *sanguinarine*, $C_{20}H_{15}O_4N+H_2O$, a colorless alkaloid, which yields bright red salts. Sanguinarine has a melting point of 212° C. and is soluble in the various organic solvents to which it imparts a fluorescence. Other alkaloids are present as *chelerythrine*, *fumarine*, and *homochelidonine*. It also contains malic and citric acids, starch, resins, coloring matter, etc. The liquid preparations invariably deposit a reddish precipitate upon the sides of the bottle. Some of the alkaloids are similar in their action to the less important opium alkaloids.

Description—Of horizontal growth, occasionally branching, more or less cylindrical, somewhat flattened, from 2 to 7 cm. in length, and from 5 to 15 mm. in diameter; externally dark brown, slightly annulate, with a few stem scars on the upper surface and numerous root scars or more or less broken filiform roots and root scars on the lower surface; fracture short, most of the rhizome showing a reddish-brown internal color, somewhat waxy, and with numerous, small, circular, yellowish fibrovascular bundles within about 1 mm. of the epidermis, pith very large. Odor slight; taste persistently acrid and bitter.

For further description see the N. F. V.

N. F. Preparations—Fluidextractum Sanguinariæ; Syrupus Pini Albæ Compositus, Syrupus Pini Albæ Compositus cum Morphina; Tinctura Sanguinariæ.

Uses—It is alterative, sternutatory, stimulant, and emetic. The dose is two to ten grains (0.125 to 0.6 Gm.).

SCOPARIUS. N. F. Scoparius

[**Scopar.**—BROOM TOPS]

Scoparius consists of the dried tops of *Cytisus scoparius* (Linné) Link (Fam. *Leguminosæ*).

Scoparius contains not more than 5 per cent of stems over 3 mm. in diameter and not more than 2 per cent of other foreign organic matter. Scoparius contains *sparteine*

(*lupinidine*), a colorless liquid alkaloid, having the composition $C_{15}H_{26}N_2$. The sulphate of this alkaloid was formerly official (see page 1167). It also contains *sarothaminine* and *Genisteine* as well as the glucoside *scoparin*, $C_{21}H_{22}O_{10}$, which probably represents the diuretic and purgativ action of the drug. (See Sparteine Sulphate, page 1167.)

Description—Stems thin, flexible, with branched twigs, from 1 to 3 mm. in thickness, five-angled; externally dark green, nearly glabrous, with numerous reddish-brown cork patches; internally yellowish, fracture short-fibrous, that of thicker pieces tough and splintery, upper leaves sessile, with often only one obovate leaflet. Odor slight, on bruising more distinct and peculiar; taste disagreeable, bitter.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Scoparii.

Uses—The dose of scoparius in dropsical complaints is fifteen to thirty grains (1 to 2 Gm.).

SOLANUM. N. F. Solanum

[**Solan.**—Horse-nettle Berries]

Solanum is the air-dried ripe fruit of *Solanum carolinense* Linné (Fam. *Solanaceæ*).

Solanum contains not more than 5 per cent of immature fruit and not more than 2 per cent of foreign organic matter. It contains two alkaloids, *solanine* and *solanidine*, also fat, resin, and volatile oil.

Description—Globose, slightly depressed, somewhat shriveled and wrinkled in drying, from 0.8 to 2 cm. in diameter, orange-yellow, glabrous, fleshy, two-celled, many seeded, calyx and pedicel usually persistent; calyx stellate pubescent, deeply five-lobed, the lobes ovate or ovate-lanceolate, acuminate and enclosing half or more of the berry; seeds orbicular, flat, yellow, smooth, shining. Odor pepper-like; taste bitter and acrid.

For further description see the N. F. V.

N. F. Preparation—Fluidextractum Solani.

Uses—It has been employed in epilepsy. Its use is similar to that of dulcamara. Dose, one drachm (4 Gm.).

TONGA. N. F. Tonga

Tonga is a mixture of equal parts of the bark of *Premna arborea* (Forster filius) Farwell (Fam. *Verbenaceæ*) and of the root of *Epipremnum pinnatum* (Linné) Engler (Fam. *Aracæ*).

Tonga contains not more than 5 per cent of foreign organic matter.

Descriptions and Tests—(See the N. F. V.)

The presence of *tongine* and a volatile oil have been reported.

Preparations—Elixir Tongæ et Salicylatum, Fluidextractum Tongæ.

Uses—It has been used as a remedy for neuralgia, but it is of doubtful value. *Dose*, 30 grains (2 Gm.).

Unofficial Drugs Containing Alkaloids

Akazga (Boundou, Quai, Ikaga, Icaya)
An ordeal poison, used in a district on the west coast of Africa. The alcoholic extract acts similarly to nux vomica

Alstonia Constricta
Australian Fever Bark
The bark of *A. constricta*, found in Australia. It contains *alstonine*, $C_{21}H_{20}O_4N_2.3\frac{1}{2}H_2O$, which is very bitter also *porphyrine* and *porphyrosine*

Aspidosperma
Quebracho (U. S. P. IX)
The dried bark of *Aspidosperma Quebracho blanco* Schlechtendal (Fam. *Apocynaceæ*), without the presence or admixture of more than 2 per cent of wood or other foreign organic matter. It contains the alkaloids *aspidospermine*, $C_{22}H_{30}O_2N_2$, *aspidospermatine*, $C_{22}H_{28}O_2N_2$, *aspidosamine*, *quebrachine*, *hydroquebrachine*, and *quebrachamine*. Quebrachine is identical with yohimbine. The commercial *aspidospermine* is usually a mixture of the above alkaloids. In addition it contains two sugars, *quebrachit* and *inosit*, and tannin. In irregular chips or in longitudinal pieces attaining a length of 14 cm. and a thickness of 35 mm.; outer corky layer from 3 to 25 mm. in thickness, brownish-gray or reddish-brown and deeply furrowed, frequently somewhat reticulate with longitudinal and shallow transverse fissures, the crevices being occasionally lined with the mycelia of a grayish mold; outer surface of bark, from which the cork has been separated, light brown or reddish-brown and usually more or less roughened; inner surface occasionally with adhering wood, otherwise light yellowish-brown to light reddish-brown, longitudinally finely striate and finely porous; fracture short-fibrous with projecting bast fibers. Nearly inodorous; taste bitter and slightly aromatic.
Uses—A respiratory sedative, used in dyspnœa (loss of voice), and in asthmatic conditions. It is also used in South America as a substitute for cinchona in the treatment of malarial fevers. Dose, thirty to sixty grains (2 to 4 Gm.). The sulphates of aspidospermine and quebrachine are used hypodermically and by the mouth in doses of one to two grains (0.065 to 0.13 Gm.)

Chelidonium
Celandine
The entire plant *Chelidonium majus* Linné (Fam. *Papaveraceæ*). It contains *chelerythrine*, *chelidonine*, *chelidoxanthin*, and *chelidonic acid*. Used as a diuretic in doses of forty grains (2.6 Gm.)

Coca
Erythroxylon
The dried leaves of *Erythroxylon Coca* Lamarck (Fam. *Erythroxylaceæ*), known commercially as Huanuco Coca, or of *E. Truxillense* Rusby, known commercially as Truxillo Coca. Yielding not less than 0.5 per cent of the ether-soluble alkaloid when assayed as directed in the U. S. P. VIII. It contains *cocaine*, $C_{17}H_{21}O_4N$, and *hygrine* and *coca-tannic acid*. It is used as a nerve stimulant in thirty- to sixty-grain doses (2 to 4 Gm.). As its preparations rapidly deteriorate, the drug and its preparations were all deleted.

Unofficial Drugs Containing Alkaloids—*Continued*

Colchici Flores
Colchicum Flowers
The flowers of *Colchicum autumnale*, found in Europe. They contain a large percentage of *colchicine*

Coptis Teeta
East Indian Goldthread
The rhizome of *C. Teeta*, found in the East Indies. It contains a very large percentage of *berberine*

Curare
Wourari
An extract made by South American Indians from plants belonging to the genus *Strychnos*. It contains an extremely poisonous alkaloid, named *curarine*

Cytisus Laburnum
Laburnum
Poisonous, narcotic. It contains *cytisine* ($C_{20}H_{27}ON_3$) and *laburnine*

Dita
Dita Bark
From the bark of *Alstonia scholaris*, found in the Philippine Islands. It contains ⅓ per cent of a bitter alkaloid, *ditamine*, and 2 per cent. of *ditain*, an uncrystallizable bitter substance

Duboisia
Duboisia
The leaves of *D. myoporoides*, found in Australia. It contains a very poisonous alkaloid, *duboisine*, which is colored reddish-brown by sulphuric acid

Ephedra Vulgaris
A cardiac stimulant and local mydriatic. It contains the alkaloid *ephedrine*

Erythrophlœum
Sassy Bark
The bark of *E. guineense*, found in Africa. It contains the colorless alkaloid *erythrophleine*. Emetic, narcotic, and astringent. Dose of the extract, two-tenths to three-tenths grain (0.015 to 0.02 Gm.)

Eschscholtzia Californica
Chamisso
Soporific and analgesic. It contains a glucoside, and an alkaloid, said to be *morphine*. The extract has been given in doses commencing with twelve and three-tenths grains (0.8 Gm.), increasing to one hundred and eighty-five grains (12 Gm.), a day

Glaucium
Horn Poppy
The plant of *G. luteum*. It contains the alkaloids *sanguinarine*, *glaucine*, and *glaucopicrine*

Gloriosa Superba
An acrid, narcotic poison. It contains two resins and a very poisonous bitter principle, *superbine*

Isopyrum Thalictroides
It contains two alkaloids, *isopyrine* and *pseudo-isopyrine*

Mandragora Officinalis
Mandrake
Anesthetic. It contains an alkaloid, *mandragorine*, and another alkaloid, both of which possess mydriatic properties

Menispermum
Yellow Parilla
Canadian Moonseed
The rhizome and roots of *Menispermum canadense* Linné (Fam. *Menispermaceæ*). It contains *menispine*, *berberine*, resin, etc. It is alterative and tonic Dose, twenty to forty grains (1.3 to 2.6 Gm.)

Muawin Bark
An ordeal poison. It contains an alkaloid, *muawinine*

Papaveris Fructus (N. F. IV)
Poppy Capsules
The dried, fully grown, unripe fruit of *Papaver somniferum* Linné (Fam. *Papaveraceæ*) from which the seeds have been separated. It contains a small amount (about 0.2 per cent) of *morphine;* also minute amounts of *narcotine*, *narceine*, *papaverine*, *rhœadine*, *codeine* and *meconic acid*.
Globular or ovoid, usually from 3 to 3.5 cm. in diameter, more or less sunken or depressed on the sides, contracted at the base into a sort of neck immediately above a tumid ring at the point of attachment with the stalk; crowned at the summit with the seven- to fifteen-rayed stigma disk; outer wall of pericarp smooth, hard, grayish-yellow to brownish-yellow, often marked with black spots; interior surface rugose, finely striated transversely, and bearing thin, brittle, membranaceous placentæ which extend from the sutures toward the center, and bear on their faces and edges numerous minute, conspicuously reticulated, reniform white seeds. Odorless; taste slightly bitter. Syrup of papaverus is made from the capsules (see page 284)
A narcotic similar to opium. Dose, fifteen grains (1 Gm.)

Papaya
Papaw
The leaves of the *Papaw* tree contain *carpaine*, a cardiac depressant

Peganum Harmala
The seed contains about 4 per cent of alkaloid, two-thirds of which is *harmaline*. It is a convulsant poison, has been used as a diaphoretic, an emmenagogue and an anthelmintic

Sophora Speciosa
The poisonous seeds of this tree contain a volatile liquid alkaloid, *sophorine*

Sabadilla Semen
Sabadilla Seed
The seeds of *Veratrum Sabadilla*. These seeds are the commercial source of *Veratrine*. Commercial *veratrine* is a mixture of alkaloids, made up of *cevadine*, *cevadilline*, *veratridine*, *sabadine* and *sabadinine*

Scopola
Scopola
This rhizome when assayed properly yields not less than 0.5 per cent of mydriatic alkaloids. Contains *scopolamine*, *hyoscyamine* and *atropine*. Used as a narcotic and mydriatic. Dose, three-fourth grain (0.045 Gm.)

Spigelia (U. S. P. IX)
Pink Root
The dried rhizome and roots of *Spigelia marilandica* Linné (Fam. *Loganiaceæ*), without the presence or admixture of more than 10 per cent of stems or other foreign matter. Rhizome horizontal or slightly oblique, more or less flexuous, somewhat branched, from 1.5 to 5 cm. in length and from 2 to 5 mm. in diameter; externally dark brown, slightly annulate, with scars of bud scales, the upper surface knotty, from approximate stem-bases, bearing cup-shaped scars; from the lower and lateral portions arise numerous long, rather coarse, sparingly branched, brittle roots; fracture short, internally differentiated into three nearly equal zones of pith, wood and bark. Few if any of the roots exhibit thin, terminal portions with the bark stripped from the slender strands of wood. Stems usually attached to the upper portion of the rhizome, nearly cylindrical, attaining a length of 6 cm. and a diameter of 3 mm., light grayish-brown to purplish-brown, nodes annulate, marked by opposite leaf scars. Odor slightly aromatic; taste bitter, pungent. Spigelia contains a bitter principle, a liquid alkaloid named by Dudley *spigeline*, resin and a trace of volatile oil, with tannin and wax. Alcohol and water extract its virtues. It is used as an anthelmintic. Dose, one drachm (4 Gm.)

Stramonii Semen
Stramonium Seed
The seed of *Datura Stramonium* Linné (Fam. *Solanaceæ*). Similar to the leaves in action and constituents (see page 1138). It contains in addition about 25 per cent of fixed oil

Unofficial Drugs Containing Alkaloids—*Continued*

Staphisagria (U. S. P. IX) Stavesacre — The ripe seeds of *Delphinium Staphisagria* Linné (Fam. *Ranunculaceæ*), without the presence or admixture of more than 2 per cent of foreign vegetable matter. Irregularly triangular, flattened, or somewhat tetrahedral, one side being convex, from 4 to 7 mm. in length and from 3 to 6 mm. in breadth; externally dark brown, becoming lighter with age, and coarsely reticulate; easily cut, showing a somewhat light brown, oily endosperm, enclosing a small embryo at the pointed end. Odor slight, disagreeable; taste intensely bitter and acrid

Staphisagria contains three alkaloids, *delphinine*, $C_{31}H_{49}O_7N$, *delphisine*, and *delphinoidine*. *Staphisagrine*, *staphisagroine*, and *calcitrapine* are also present with fixed oil, protein compounds, mucilage, etc. The alkaloids are soluble in chloroform, fixed oils, alcohol, and ether, and an oleoresin made with petroleum benzin is an active preparation

Uses—It is used principally externally for killing body vermin, and is very poisonous resembling aconite in action. Dose, one grain (0.065 Gm.)

Tabacum Tobacco — The commercial dried leaves of *Nicotiana Tabacum* Linné (Fam. *Solanaceæ*). It contains *nicotine*, a liquid alkaloid, very acrid and poisonous. Tobacco is sedative and emetic in doses of one to five grains (0.065 to 0.32 Gm.)

Veratrum Nigrum Black Hellebore — This drug grown in Central Europe is used as a substitute for veratrum album. It contains *jervine*

Yohimba Bark — The bark of the species *Tabeimontana* containing *yohimbine*. Yohimbine is used as an aphrodisiac

Xanthorrhiza Yellow Root — Tonic. Dose, forty grains (2.6 Gm.). It contains *berberine*

Unofficial Alkaloids and their Salts, with Allied Products

Alstonine, $C_{21}H_{20}O_4N_2.3\frac{1}{2}H_2O$ — From the bark of *Alstonia constricta*. A brownish-yellow, amorphous powder, readily soluble in alcohol

Anagyrine, $C_{14}H_{18}O_2N_2$ — A yellowish, amorphous, hygroscopic, poisonous alkaloid, from *Anagyris fœtida*. Soluble in water, alcohol, and ether

Analgen (Orthoethyoxyana-monobenzoylamidochino-line), $C_{18}H_{16}O_2N_2$ — Antipyretic and antirheumatic. Dose, eight to fifteen grains (0.5 to 1 Gm.), repeated, if necessary, to seventy-five grains (4.86 Gm.) a day

Antispasmin (Narcein Sodium-Sodium Salicylate) $C_{23}H_{26}O_8N.Na+3C_6H_4(OH)COONa$ — Hypnotic and analgesic. Dose, one-half to one grain (0.03 to 0.06 Gm.)

Arecoline Hydrobromide, $C_8H_{13}O_2N.HBr$ — A liquid alkaloid obtained from *areca* (*betel*) nuts

Aspidospermine, $C_{22}H_{30}O_2N_2$ — From the bark of *Aspidosperma Quebracho*. It is a weak base, forming amorphous salts. The hydrochloride is given in doses of one-thirtieth to one-twentieth of a grain (0.002 to 0.003 Gm.)

Bebeerine, $C_{18}H_{21}O_3N$ — From the bark of *Nectandra Rodiæi*. A pale yellow, amorphous powder, of a resinous aspect, inodorous, very bitter, very slightly soluble in water; inflammable and of an alkaline reaction. *Bebeerine sulphate* is given in doses of two to five grains (0.125 to 0.3 Gm.)

Benzoyl Ecgonine, $C_{16}(H).H_{18}O_4N$, or $C_9H_{14}(C_7H_5O)O_3N$ — Cardiac stimulant. Prepared by heating cocaine in aqueous solution to decomposition

Benzoyl Tropeine, $C_{15}H_{19}O_2N+2H_2O$ — Local anesthetic

Berberine, $C_{20}H_{17}O_4N$ — From the bark of the root of *Berberis vulgaris* and others. It occurs in minute yellow crystals, has a bitter taste, is soluble in 100 parts of cold water, and insoluble in ether. Its medicinal action is similar to that of quinine. Dose, one to eight grains (0.065 to 0.5 Gm.)

Betaine Trimethyl-glycoll — An alkaloid found in the juice of the sugar beet

Blennostasine — Supposed to be a derivative of a cinchona alkaloid. Used in hay fever, influenza, and colds, in doses of fifteen to sixty grains (1 to 4 Gm.)

Boldine — From the leaves of *Peumus Boldus*. It imparts to water a bitter taste, is soluble in alcohol, ether, chloroform, etc., and is colored red by nitric and sulphuric acids. The yield of alkaloid is about $\frac{1}{2}$ per cent.

Buxine — From the bark of *Buxus sempervirens*. It is identical with the bebeerine of nectandra bark

Chelerythrine — From *Chelidonium majus*. This alkaloid is identical with *sanguinarine*. It is an acrid poison

Chinoidine (Quinoidine) — A mixture of alkaloids, mostly amorphous, obtained as a by-product in the manufacture of the crystallizable alkaloids from cinchona. Dose, five to thirty grains (0.32 to 2 Gm.)

Chinol, Quinoline monohypochlorite, $C_9H_6N.Cl.O$ — Antipyretic and analgesic. Dose, three to five grains (0.2 to 0.32 Gm.)

Chinoline (Quinoline, Leucoline), C_9H_7N — An artificial alkaloid. A colorless, oily liquid. Sp. gr. 1.081 at 10° C. (50° F.). Antipyretic and antiseptic

Chlorogenine — Identical with *alstonine* (see above)

Cicutine — From *Cicuta virosa*. A volatile alkaloid. An acrid narcotic and poison.

Cinchonidinæ Salicylas, Cinchonidine Salicylate, $C_{19}H_{22}ON_2C_7H_6O_3$ — Antirheumatic. Dose, fifteen to twenty grains (1 to 1.3 Gm.) a day

Cinchonine, $C_{19}H_{22}ON_2$ — An alkaloid obtained from the bark of various species of Cinchona. Insoluble in water. Used in making elixirs, etc., as it is soluble in alcohol

Conhydrine, $C_8H_{17}ON$ — From *Conium maculatum*. It occurs in pearly, iridescent plates, which are easily fusible; odor similar to that of coniine

Coniine, $C_8H_{17}N$ — From *Conium maculatum*. A volatile alkaloid, inflammable, strong alkaline reaction, strong odor, soluble in water, alcohol, ether, chloroform, etc. Used as an antispasmodic. Dose, one-fourth of a grain (0.015 Gm.). *Coniine hydrobromide* is given in doses of one-sixteenth of a grain (0.004 Gm.)

Unofficial Alkaloids and their Salts, with Allied Products—*Continued*

Cornutine Citrate	An alkaloid from ergot, the activity of which is probably due to ergotoxin
Corydaline, $C_{22}H_{27}O_4N$	From the tubers of *Dicentra canadensis*. A white, amorphous powder; its solution has a very bitter taste; it is a tertiary base
Curarine, $C_{18}H_{35}N$?	From *curare*. It occurs in colorless prisms having a very bitter taste. It is colored red by nitric acid
Cytisine, $C_{11}H_{14}ON_2$	From *Cytisus Laburnum*. It occurs in white crystals, is inodorous, and has a bitter, somewhat caustic taste, and an alkaline reaction. Soluble in water and alcohol. It is colored orange-yellow by nitric acid
Daturine	See page 1138. Dose, one sixty-fourth of a grain (0.001Gm.)
Delphinine, $C_{22}H_{35}O_6N$	From the seed of *Delphinium Staphisagria*. It occurs in flat prisms; taste bitter, followed by persistent tingling. Nearly insoluble in water
Diacetylmorphine (U. S. P. IX) Heroine	An alkaloid [$C_{21}H_{23}O_5N$ or $C_{17}H_{17}(O.C_2H_3O)_2ON$] prepared from morphine by acetylization. When alkaloidal morphine is heated with acetylchloride, the synthetic alkaloid, diacetylmorphine is produced. A white, crystalline powder. Without odor. Its saturated alcoholic solution is alkaline to moistened litmus paper. One Gm. of Diacetylmorphine dissolves in about 1700 cc. of water, 31 cc. of alcohol, 1.4 cc. of chloroform, and in 100 cc. of ether at 25° C. Uses—This alkaloid, usually known as *heroin* or *heroine*, was formerly much used as a sedative in cough mixtures and to relieve moderate pain, but a Federal law was passed in 1925 prohibiting its importation and the importation of opium for its manufacture because of its dangerous habit-forming character. Codeine is largely used in its place. The dose was one-twentieth grain (0.003 Gm.)
Diacetylmorphine Hydrochloride Heroine Hydrochloride	The hydrochloride [$C_{21}H_{23}O_5N.HCl+H_2O$ or $C_{17}H_{17}(O.C_2H_3O)_2ON.HCl+H_2O$] of the alkaloid diacetylmorphine. A white, crystalline powder, without odor. One Gm. of Diacetylmorphine Hydrochloride dissolves in 2 cc. of water at 25° C.; soluble in alcohol; insoluble in chloroform or ether at 25° C. Used the same as for diacetylmorphine
Duboisine	From several species of *Duboisia*. It crystallizes in fine, colorless needles. Used as a substitute for atropine. Dose, one sixty-fourth of a grain (0.001 Gm.)
Ergotoxine, $C_{35}H_{41}O_6N_5$	An active alkaloid obtained from ergot
Erythrophleine Hydrochloride	Obtained from *Erythrophlæum guineense* (Sassy bark). Used in place of cocaine. Dose, one-eighth of a grain (0.008 Gm.)
Ethyl-oxy-Caffeine	Called also Ethoxycaffeine. Given in migraine, in doses of six to eight grains (0.38 to 0.5 Gm.)
Geissospermine, $C_{19}H_{24}O_2N_2.H_2O$	From *Geissospermum læve*. It occurs in small white prisms, nearly insoluble in ether and water, and readily soluble in alcohol and dilute acids
Gelsemine, $C_{24}H_{28}O_4N_2$	From *Gelsemium sempervirens*. It occurs in an amorphous, white powder, of a very bitter taste and an alkaline reaction, slightly soluble in cold water. It is colored red, changing to purple when heated with sulphuric acid. *Gelsemine hydrochloride* has been given in doses of one-sixteenth of a grain (0.004 Gm.)
Glaucine	From *Glauceum luteum*. A white, crystalline powder
Glaucopicrine	From *Glauceum luteum*. A white, crystalline powder
Guaranine	From *Paullinia sorbilis*. Identical with caffeine
Hydrastine, $C_{21}H_{21}O_6N$ (U. S. P. IX)	From hydrastis or prepared synthetically. It is made by adding hydrochloric or sulphuric acid to an alcoholic tincture of hydrastis; the berberine is deposited as a crystalline precipitate, ammonia is added to the filtered mother liquor, and the precipitated hydrastine is purified by recrystallization. In white to creamy white, glistening prisms or as a white, microcrystalline powder; permanent in the air. Almost insoluble in water; 1 Gm. is soluble in 170 cc. of alcohol, 1.4 cc. of chloroform, and in 175 cc. of ether at 25° C. also in 22 cc. of alcohol at 60° C. It melts at about 131° C. (For tests of identity and uses see *Hydrastinæ Hydrochloridum*, page 1145)
Hydrastinine Hydrochloride, $C_{11}H_{11}O_2N.HCl$ (U. S. P. IX)	The hydrochloride of an alkaloid obtained by the oxidation of hydrastine. Made by acting on colorless hydrastine with oxidizing agents. It can also be prepared from narcotine and from berberine. Light yellowish needles, or a yellowish-white, crystalline powder. Without odor. One Gm. of Hydrastinine Hydrochloride dissolves in 195 cc. of chloroform, and in 1820 cc. of ether at 25° C.; very soluble in water and alcohol. It melts at about 210° C. with partial decomposition. In an aqueous solution of the salt (1 in 20), potassium dichromate T.S. produces a precipitate which redissolves if gently heated, but on cooling the solution it separates again in glistening needles. No weighable ash remains on incinerating 0.1 Gm. of Hydrastinine Hydrochloride. In an aqueous solution of the salt (1 in 20), bromine T.S. produces a yellow precipitate, which is completely soluble in ammonia water, producing an almost colorless solution (*hydrastine*). Add slowly 4 or 5 drops of a solution of sodium hydroxide (1 in 7) to a solution of 0.2 Gm. of the salt in 3 cc. of distilled water; each drop causes a milky turbidity, which disappears again on shaking. From this solution, after standing for some time, pure white hydrastinine separates, and the supernatant fluid is almost colorless. Add a few drops of ammonia water to 1 cc. of an aqueous solution of Hydrastinine Hydrochloride (1 in 20): no turbidity is produced (*foreign alkaloids*) Hydrastinine hydrochloride is an oxytocic, in doses of one-half to one grain (0.032 to 0.065 Gm.)
Hygrine	From the leaves of *Erythroxylon Coca*. A volatile alkaloid, of a pale yellow color and a burning taste
Hyoscine	Obtained from *Hyoscyamus niger* in the process for obtaining hyoscyamine, and also by boiling hyoscyamine with baryta water, when decomposition takes place, forming hyoscine and hyoscinic acid. Dose, one sixty-fourth of a grain (0.001 Gm.)
Jervine, $C_{26}H_{37}O_3N.2H_2O$	From *Veratrum album*. It occurs, when pure, as a white powder, tasteless, insoluble in water and ether, but soluble in alcohol and chloroform

Unofficial Alkaloids and their Salts, with Allied Products—*Continued*

Kairine, $C_{10}H_{13}ON.HCl.H_2O$	The hydrochloride of an artificial alkaloid prepared from chinoline. It occurs in commerce as a grayish or yellowish, crystalline powder, having a slight phenol-like odor, and a saline, bitter, somewhat aromatic taste, soluble in boiling water. Dose, fifteen grains (1 Gm.)
Kairoline, Tetrahydromethylquinoline or Tetrahydroethylquinoline	Antipyretic. The sulphates are the commercial salts
Laurotetanine	An alkaloid found in a number of plants belonging to the Laurinæ. A powerful poison, acting like strychnine
Lobeline	From *Lobelia inflata*. It is a volatile, yellow, somewhat aromatic liquid, having an acrid taste. Soluble in alcohol, ether, and fixed oils
Lupinine, $C_{10}H_{19}ON$	From different species of *Lupinus*. It occurs in colorless, rhombic prisms having a fruity odor and a very bitter taste
Lupuline	From *Humulus Lupulus*. A liquid alkaloid which has a strong coniine-like odor and an alkaline taste
Menispermine, $C_{18}H_{24}O_2N_2$	From *Cocculus Indicus*
Muscarine, $C_5H_{15}O_3N$	From *Amanita muscaria*. A colorless, crystalline powder, deliquescent, sparingly soluble in chloroform, and insoluble in ether
Nicotine, $C_{10}H_{14}N_2$	From *Nicotiana Tabacum*. A poisonous, oily liquid. It has an unpleasant tobacco-like odor, a burning taste, and a strongly alkaline reaction
Oxyacanthine, $C_{19}H_{21}O_3N$	From *Berberis vulgaris*. It is white, turning yellow on exposure to sunlight, having a bitter taste and an alkaline reaction. Soluble in 30 parts of boiling alcohol and in 1 part of cold alcohol, insoluble in water. Sulphuric acid colors it brown-red, turning to bright red on being heated
Parthenine	From *Parthenium Hysterophorus*. Used in doses of seven to ten grains (0.4 to 0.65 Gm.) in neuralgia
Pelosine	From *Chondodendron tomentosum*. It is amorphous, insoluble in water, slightly soluble in ether
Piperine, $C_{17}H_{19}O_3N$	A crystalline alkaloid occurring in black and white pepper
Piturine, C_6H_8N	From the leaves of *Duboisia Hopwoodii*. A colorless liquid, of a nicotine odor and an acrid taste; on exposure to light it turns yellow and brown; freely soluble in water, alcohol, etc.
Quebrachine, $C_{21}H_{26}O_3N_2$	From the bark of *Aspidosperma Quebracho*. It yields crystallizable salts, and is colored yellow by sunlight
Quinidine Sulphate, $(C_{20}H_{24}O_2N_2)_2.H_2SO_4+2H_2O$	Obtained from the mother liquors after the crystallization of the quinine
Sanguinarine, $C_{20}H_{15}O_4N+H_2O$	From *Sanguinaria canadensis*. It occurs in white crystals, having a bitter, acrid taste; soluble in ether and alcohol
Solanine	From *Dulcamara* and other plants. Dose, one grain (0.06 Gm.)
Sophorine	From the seeds of *Sophora speciosa*. A poisonous alkaloid
Sparteine Sulphate, $C_{15}H_{26}N_2.H_2SO_4.5H_2O$ (U. S. P. IX)	The sulphate of sparteine, a liquid alkaloid obtained from *Cytisus Scoparius* (Linné), Link (Fam. *Leguminosæ*). The salts of sparteine are mostly crystallizable, although the alkaloid itself is liquid. Sparteine is identical with *lupinidine* obtained from *yellow lupin seeds*. In colorless, rhombohedral crystals, or as a crystalline powder. It is hygroscopic, odorless and having a slightly saline and somewhat bitter taste. One Gm. of Sparteine Sulphate dissolves in 1.1 cc. of water and in 3 cc. of alcohol at 25° C.; insoluble in chloroform or ether. Uses—Sparteine sulphate is a cardiac stimulant and narcotic. Dose, one-sixth of a grain (0.01 Gm.)
Staphisagrine, $C_{22}H_{33}O_5N$	From *Delphinium Staphisagria*. It is amorphous, very soluble in ether and in 200 parts of water
Thalline, Tetrahydroparaquinanisol, $C_9H_6H_4N(OCH)_3$	A hemostatic. The sulphate and tartrate are powerful antipyretics. Dose, from four to eight grains (0.25 to 0.5 Gm.)
Theine	See *Caffeine* (page 1150)
Theobromine, $C_7H_8O_2N_4$	From *Theobroma Cacao*. It occurs in minute, colorless or white, bitter crystals, sparingly soluble in water, alcohol, and ether
Tropacocaine Hydrochloride, $C_{15}H_{19}O_2N.HCl$	An alkaloid from coca said to possess greater anesthetic activity than cocaine
Veratroidine, $C_{51}H_{78}O_{16}N_2$	From *Veratrum viride*. It is a white powder, of a bitter taste, soluble in alcohol, ether, chloroform, etc. It is colored yellow by sulphuric acid
Yohimbine, $C_{22}H_{28}O_3N_2.H_2O$	The hydrochloride is used medicinally as an aphrodisiac. The alkaloid is obtained from *yohimboa bark* (*Corynanthe Yohimbi*)

CHAPTER LXXIV

VITAMINS

For centuries a disease called *beri-beri* was prevalent in oriental countries, technically it was known as *polyneuritis*. It was commonest among the poorer classes, particularly those who lived upon rice and fish, and was commonly believed to be due to some toxic substance present in the food, although no evidence of this fact had ever been presented. In 1897 a Dutch scientist named Eijkman produced experimentally a disease resembling beri-beri in pigeons which had been fed on polished rice. Nutrition experts and food chemists had up to recent years classified food values upon the four great nutritional elements: *fats*, *carbohydrates*, *proteins*, and *mineral salts*. Calorific values, the fuel needs of the human engine, had been calculated with great exactness, and the body needs in this respect had been very thoroughly studied and established. In 1912, Casmir Funk, a Polish physiologist and chemist, did some experimental work in New York along the line of Eijkman's observations, and made the discovery that pigeons in which experimental polyneuritis had been produced and in which the disease had been allowed to progress until the birds were in a moribund condition, could be revived and restored to normal health by the administration of minute amounts of the pericarp of the rice grain, the material that had been removed in polishing the rice. He named the unknown and unidentified principle a *vitamin*, because he believed it to belong to the *amino* group of organic compounds and because it was of *vital* necessity to life.

McCollum, at present of Johns Hopkins University, who at that time was an instructor in the University of Wisconsin, made nutrition studies his hobby and, building upon the foundations laid by Eijkman, Funk, and certain Japanese investigators, has since become one of the foremost authorities upon this important subject. The single vitamin of rice pericarp of Funk has been augmented since 1912 by the discovery of a number of others which have still retained the generic name, and which are distinguished by the letters of the alphabet in regular order. At the present time at least seven vitamins are recognized, known as *Vitamins* A, B, C, D, and E respectively, and vitamins X and P, which have so recently been announced that little is known regarding them.

Vitamin A, usually called *Fat Soluble A*, on account of its principal origin, is especially abundant in cod liver oil, butter, egg yolk, and glandular tissues of fowls and food animals. It has been found in but few vegetable fats, but abounds in the green leaves of food plants, as spinach and lettuce, and in the forms of certain cereal grains. Vitamin A protects the individual against a disease of the eyes called *xerophthalmia*, and benefits the organism in other ways.

The vitamin which Funk had discovered was found to exist plentifully in the husks of many cereals, and also in cow's milk. This was called *Vitamin B* or *Water Soluble B*. A third vitamin was later discovered by the Norwegian scientists, Holst and Frolich, particularly in fresh vegetables and fruits. This is called *Vitamin C* or *Water Soluble C* and has antiscorbutic properties in particular.

Cabbage, tomatoes, and orange juice are particularly rich in Vitamin C. A fourth vitamin, called *Vitamin D*, was discovered later, which stimulates

the growth of yeast and probably other microörganisms and which possesses antirachitic properties; and the latest addition called *Vitamin E*, which has been found in wheat and other cereal grains, is essential to the reproduction of the individual and hence has been called the *fertility* vitamin.

Vitamins are called "food accessory" or "growth promoting" substances or "unidentifiable dietary factors". There are no chemical tests for their detection nor have they been extracted and isolated in a state of purity.

Their presence is determined by feeding experiments upon fowls and animals, particularly upon white rats. These experiments must be carefully controlled and must cover a sufficiently long period of time to warrant the establishment of conclusions regarding the presence or absence of these mysterious factors. For fuller information upon the subject see cod liver oil, page 1187, also McCollum's "Newer Knowledge of Nutrition" and the "Vitamine Manual" by Eddy.

Nostrums purporting to contain vitamins in concentrated form are usually misleading in their claims. Any individual who eats normally a variety of foods, especially an abundance of dairy products and fresh vegetables and fruits, is in no danger of vitamin starvation.

The most recent work in the chemistry of the vitamins indicates that the water-soluble vitamins are amino compounds, while the fat soluble vitamins have a composition resembling cholesterol.

The most noteworthy discovery in connection with the studies upon vitamins is that certain of them appear to be capable of development by exposure of food products to the action of ultra violet light. Thus cottonseed oil, which ordinarily is devoid of vitamins, has been given certain qualities by exposure to such rays, as are comparable to the effect of certain natural vitamin containing foods. This has also been done with cholesterol.

CHAPTER LXXV

PRODUCTS FROM ANIMAL SUBSTANCES

The animal products of pharmaceutical interest are not numerous, but some of them are very important.

Protein substances, or, as formerly called, *proteids*, are any one of a group of complex substances forming the essential constituents of living cells and from which all animal and vegetable tissues are built up. They are combinations of amino acids or their derivatives and all contain carbon, hydrogen, oxygen, and nitrogen. Sulphur also occurs in most of the groups, and phosphorus and iron in a few. They are mostly colloidal, are insoluble in ether and alcohol, are coagulated by heat, and may be decomposed by mineral acids, caustic alkalies, proteolytic enzymes and putrefying bacteria, the ultimate products being amino acids. The amino acids are as follows: *glycine*, *alanine*, *serine*, *cysteine*, *cystine*, *phenylalanine*, *tyrosine*, *histidine*, *tryptophane*, *valine*, *leucine*, *isoleucine*, *aspartic acid*, *glutamic acid*, *ornithine*, and *lysine*.

Simple proteins, or those yielding only amino acids on hydrolysis, are represented by *albumins*, *globulins*, *glutelins*, *albuminoids*, *histons*, and *protamins*. *Conjugated proteins*, those combining some other molecule, but not as a salt, are represented by *nucleo-proteins*, *glycoproteins*, *phosphoproteins*, *nucleo-albumins*, *hemoglobins*, *lecithoproteins*.

Derived proteins, resulting from hydrolytic change, are represented by *proteins*, *metaproteins*, *proteoses*, *peptones*, *and peptids*.

The term *protide* has recently been adopted by international agreement to distinguish such nitrogenous substances as yield one or more amino acids by hydrolysis. The term is practically synonymous with protein.

Ptomaines or cadaveric alkaloids are produced when animal substances are subjected to putrefaction or fermentative processes. Many of them are intensely poisonous. They have an alkaline reaction, forming salts like the alkaloids, and may be volatile or fixed, fluid or solid, crystalline or amorphous. Some ptomaines are tasteless and odorless, others have an intensely bitter taste and an aromatic odor. The alkaloids from animal excretions have been given the name of *leucomaines*; nitrogenous poisonous substances derived from animal tissues which are not alkaloids are termed *toxalbumins*.

Modern researches in physiological chemistry, especially the glandular secretions, have revealed the fact that an important part is played by these secretions, many of which contain definite active principles such as suprarenalin and thyroxin. These principles are produced in specialized cell structures (glands) and conveyed by the blood to other parts of the body where their effects are produced. The term *hormone* has been loosely applied to all such substances, and the term *organotherapy* is used to indicate the branch of therapeutics in which these animal glands, their extracts, or their active principles are employed. The term *endocrins* is also applied to the glands.

Serums and vaccines have become important agents in the modern treatment of disease, and these will be discussed in the Chapter on Biological Products.

The animal products of interest in pharmacy are grouped according to the *class* to which they belong, as follows: 1. Mammalia. 2. Pisces. 3. Aves. 4. Insecta. 5. Reptilia. 6. Annelida. There are no official products from the third, fifth, or sixth classes.

Official Products Derived from the Class Mammalia

ADEPS. U.S. Lard

The standards and tests will be found under *Fats*, page 1040.

ADEPS BENZOINATUS. U.S. Benzoinated Lard

The standards and tests will be found under *Fats*, page 1041.

ADEPS LANÆ. U.S. Wool Fat

The standards and tests will be found under *Fats*, page 1042.

ADEPS LANÆ HYDROSUS. U.S. Hydrous Wool Fat

The standards and tests will be found under *Fats*, page 1043.

SEVUM PRÆPARATUM. U.S. Prepared Suet

The standards and tests will be found under *Fats*, page 1043.

SEVUM BENZOINATUM. N.F. Benzoinated Suet

The standards and tests will be found under *Fats*, page 1044.

GELATINUM. U.S. Gelatin

[Gelat.]

A product obtained from animal tissues, such as skin, ligaments, and bones.

Preparation—Bones, cartilaginous material, such an tendons, and hide contain substances called *collagens* which are capable of undergoing hydrolysis when boiled with water. The collagens yield in this manner the adhesive principle *glutin*, which predominates in glue, and the gelatinizing principle *chondrin*, which predominates in gelatin. Glue and gelatin therefore are closely related products, the latter being made from sound selected stock.

Bone gelatin, which is the finest variety for edible use and pharmaceutical purposes, is made from clean bones which are first treated with hydrochloric acid to remove calcium phosphate, the residue used in gelatin manufacture being known as *ossein*. The ossein is boiled with water, the solution clarified by filtration, decolorized with bone black if necessary, and evaporated to a degree of concentration, which, upon cooling, produces a stiff jelly. This is cut into slabs and dried upon aluminum wire netting under sanitary conditions, in a current of warm, dry, clean air. The sheets are marketed in convenient sizes or the material may be cut, granulated or powdered by mechanical means. Low grade gelatin is sometimes prepared by the use of bleaching agents such as sulphur dioxide, and such material sometimes contains injurious amounts of metallic impurities such as copper, lead, zinc, and arsenic, which are excluded by the official text. For capsule making only, a special form of gelatin is permitted in which the bright sparkling appearance and freedom from decomposition is produced by the use of a limited amount of sulphur dioxide.

Description and Physical Properties—In sheets, flakes, shreds, or as a coarse or fine powder. It is colorless or yellowish, and has a very slight, characteristic odor and taste. When dry, it is stable in the air, but when moist or in solution, it decomposes.

Gelatin is insoluble in cold water, but swells and softens when immersed in it, gradually absorbing from 5 to 10 times its own weight of water. It is soluble in hot water, acetic acid, and in a hot mixture of glycerin and water. It is insoluble in alcohol, chloroform, ether, benzene, carbon disulphide, and in fixed or volatile oils.

Tests for Identity—An aqueous solution of Gelatin (1 in 100) yields no precipitate with copper sulphate T.S. or mercuric chloride T.S., but is precipitated by solutions of chromium trioxide or trinitrophenol T.S. Even a very dilute solution of Gelatin (1 in 5000) is at once rendered turbid by the addition of tannic acid T.S.

Tests for Purity—A hot solution of Gelatin in distilled water (1 in 40) is free from a putrid odor, and is not more than slightly acid to litmus paper. In a layer 2 cm. in thickness the solution is only slightly opalescent and on cooling to 6° C., and standing for several hours, it forms a firm, transparent or translucent jelly.

Incinerate 0.5 Gm. of Gelatin: it yields not more than 2 per cent of ash. Dissolve this ash with the aid of heat in a slight excess of hydrochloric acid and a few drops of nitric acid: the resulting solution diluted with distilled water to 25 cc. meets the requirements of the test for *heavy metals*, page 1519.

Heat 1.5 Gm. of Gelatin with 30 cc. of hydrochloric acid (1 in 4) in a 150 cc. Erlenmeyer flask on a water bath, and, when the Gelatin has dissolved, add 3 cc. of bromine T.S., and heat on a water bath, for 30 minutes, shaking the flask occasionally. Then add 0.5 Gm. of potassium iodide and follow it with 0.5 cc. of 25 per cent solution of stannous chloride. Heat the solution for five minutes on a water bath, cool and subject it to the test for *arsenic*, page 1512. The stain, if any, is not greater than that produced in a test made with the same quantities of the reagents and 2 cc. of the standard arsenic test solution.

Dissolve 20 Gm. of Gelatin in 150 cc. of hot distilled water in a flask having a round bottom and a long neck, add 5 cc. of phosphoric acid and 1 Gm. of sodium bicarbonate, and at once connect the flask with a condenser. Distil 50 cc., receiving the distillate under the surface of 50 cc. of tenth-normal iodine. Acidulate the distillate with a few drops of hydrochloric acid, add 2 cc. of barium chloride T.S., and heat on a water bath until the liquid is nearly colorless. The precipitate of barium sulphate, if any, when filtered, washed and ignited, weighs not more than 0.003 Gm., corresponding to not more than 0.004 per cent of sulphur dioxide, correction being made for any sulphate which may be present in 50 cc. of the tenth-normal iodine.

NOTE—Gelatin to be used for capsules for medicines may contain not more than 0.15 per cent of sulphur dioxide.

U. S. P. Preparation—Gelatinum Glycerinatum.

Uses—Gelatin is largely used in pharmacy to coat pills and form capsules, and as a vehicle for suppositories.

PEPSINUM. U. S. Pepsin

[Pepsin.]

Pepsin is a substance containing a proteolytic enzyme obtained from the glandular layer of the fresh stomach of the hog, *Sus scrofa* var. *domesticus* Gray (Fam. *Suidæ*).

Pepsin digests not less than 3000 times its own weight of freshly coagulated and disintegrated egg albumen. Pepsin of a higher digestive power may be brought to this standard by admixture with pepsin of a lower digestive strength or with lactose.

Preparation—Pepsin is made from hogs' stomachs which are macerated in water acidulated with hydrochloric acid, for several days, with frequent stirring. The strained liquid, if not clear, is clarified by allowing it to stand for twenty-four hours, and decanting. Sodium chloride, or other suitable precipitating medium is then dissolved in the solution to cause the precipitation of the pepsin, which comes to the surface. After several hours the floating pepsin is skimmed from the surface and purified by solution and reprecipitation. *Purified pepsin*, or *scale pepsin*, is made by concentrating an acidulated solution of pepsin in a vacuum apparatus and spreading the thick solution on glass plates to form scales, as is done with the scale salts of iron. It is in the form of yellowish scales. It is sometimes prepared in thicker scales which are broken up to form *granular pepsin*. When in these forms, pepsin is very soluble, and analysis has shown the presence of as much as ten per cent of free hydrochloric acid. One of the best forms of commercial pepsin is the "*spongy*" variety said to be produced by drying the pepsin solution in vacuum driers which causes the pepsin to puff and assume a spongy form.

An insoluble pepsin freed from acid is also largely used for dispensing in powders and capsules, as it is not hygroscopic, and can be dispensed without becoming moist. This form is said to consist of the dried and pulverized stomach tissue containing the unremoved pepsin.

Description and Physical Properties—Lustrous, white or pale yellow, transparent or translucent scales, granules or spongy masses, or a fine, white or cream-colored, amorphous powder free from any offensive odor, and having a slightly acid or saline taste. It is not more than slightly hygroscopic.

Pepsin is freely soluble in water, the solution being more or less opalescent. It is nearly insoluble in alcohol, chloroform, and ether.

Dry Pepsin is not injured by heating to 100° C. The activity of Pepsin in solution is destroyed by alkalies or by temperatures exceeding 70° C.

Tests for Identity—An aqueous solution of Pepsin (1 in 50) is acid to litmus paper.

An aqueous solution of Pepsin yields precipitates with solutions of tannic or gallic acid and with solutions of the salts of many heavy metals.

On heating a saturated solution of Pepsin in acidulated water to 100° C., it becomes milky or yields a light, flocculent precipitate and loses all proteolytic power.

Assay—Mix 25 cc. of normal hydrochloric acid with 275 cc. of distilled water. Dissolve 0.1 Gm. of Pepsin in 150 cc. of this acid. Select a hen's egg, which is not less than five and not more than twelve days old and has been kept in a cool place, and immerse it in boiling water during fifteen minutes. As soon as the egg has sufficiently cooled to handle, remove the shell and pellicle and all of the yolk and at once rub the albumen through a clean, dry, hair or brass, No. 40 sieve, reject the first portion that passes through the sieve, and place 10 Gm. of the succeeding portion in a wide-mouthed bottle of 100 cc. capacity. Immediately add 20 cc. of the acid, and stir the mixture with a rubber-tipped glass rod so as to separate thoroughly the particles of albumen from each other. Rinse the rod with 15 cc. more of the acid and, after warming the mixture to 52° C., add exactly 5 cc. more of the acidulated solution of Pepsin. At once cork the bottle securely, invert it three times, and place it in a bath that has been previously regulated to maintain a temperature of 52° C. Keep the bottle at this temperature for two and one-half hours, agitating the contents every ten minutes by inverting it once. Then remove it from the bath, pour the contents into a conical measure having a diameter not exceeding 1 cm. at the bottom, and transfer the undigested egg albumen, which adheres to the sides of the bottle, to the measure with the aid of small portions (about 15 cc. at a time) of distilled water, until the total amount used measures 50 cc. Stir the mixture well and allow it to stand for half an hour. The deposit of undissolved albumen does not measure more than 1 cc.

The relative proteolytic power of pepsin, stronger or weaker than that just described, may be determined by ascertaining through repeated trials the quantity of the Pepsin solution made as directed in the assay, required to digest, under the prescribed conditions, 10 Gm. of boiled and disintegrated egg albumen. Divide 15,000 by this quantity expressed in cc. to ascertain how many parts of egg albumen one part of Pepsin will digest.

Preserve in well-closed containers.

N. F. Preparations—Elixir Cinchonæ Alkaloidorum, Ferri et Pepsini; Elixir Pepsini (from Glycerite); Elixir Pepsini, Bismuthi et Strychninæ; Elixir Pepsini et Bismuthi; Elixir Pepsini et Ferri; Elixir Pepsini et Rennini Compositum; Glyceritum Pepsini; Liquor Ferri Peptonati; Liquor Ferri Peptonati et Mangani; Liquor Pepsini (from Glycerite); Liquor Pepsini Antisepticus; Liquor Pepsini Aromaticus; Pepsinum Saccharatum; Succus Citri et Pepsini (from Glycerite); Vinum Pepsini (from Glycerite).

Uses—Pepsin is used to aid the digestion of food and is given in dyspepsia in doses of three to thirty grains (0.2 to 2 Gm.). Pepsin is only active when in an acid medium of the hydrogen ion concentration corresponding to about 0.2 per cent of free hydrochloric acid. More than 18 per cent of alcohol in pepsin solutions and much agitation cause rapid deterioration. Pepsin is destroyed in the presence of alkalies and also by metallic salts, such as those of copper, lead, silver, mercury, bismuth, etc.

PEPSINUM SACCHARATUM. N.F. Saccharated Pepsin

[Pepsin. Sacchar.]

	Metric	Alternative
Pepsin	**10 Gm.**	175 gr.
Lactose, recently dried and in very fine powder	**90 Gm.**	3 oz. av. 262 gr.
To make	**100 Gm.**	4 oz. av.

Triturate the pepsin with the lactose to a uniform, fine powder. Keep the product in well-stoppered bottles. The dose is fifteen grains (1 Gm.) representing about 1½ grains of pepsin.

LIQUOR PEPSINI. N. F. Solution of Pepsin

[Liq. Pepsin.]

	Metric	Alternative
Glycerite of Pepsin (see note below)	**50 cc.**	1 fl. oz. 288 min.
Diluted Hydrochloric Acid	5 cc.	77 min.
Glycerin	**315 cc.**	10 fl. oz. 38 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix them by very gentle agitation.

NOTE—Pepsin solutions are reduced in proteolytic activity by agitation and storage, particularly when at or above normal room temperature. To insure the dispensing of this solution at standard strength, it is strongly recommended that an excess of pepsin, above that directed in the formula, of 25 per cent to 50 per cent be used in preparing this Solution to allow for such loss of activity, and that it be stored in a cool place.

Solution of Pepsin is a transparent, yellowish liquid, with a characteristic odor, an acid, saline, characteristic taste, and an acid reaction.

One cc. of this Solution will digest 10 Gm. of egg albumin, carrying out the test according to the details of the U. S. P. X assay under *Pepsinum*, page 1173.

The dose is two fluidrachms (8 cc.), representing about one-half grain of pepsin.

LIQUOR PEPSINI ANTISEPTICUS. N. F. Antiseptic Solution of Pepsin

[Liq. Pepsin. Antisept.]

	Metric	Alternative
Pepsin (see note below)	**50.0 Gm.**	1 oz. av. 293 gr.
Diluted Hydrochloric Acid	**5.0 cc.**	77 min.
Glycerin	**50.0 cc.**	1 fl. oz. 288 min.
Alcohol	**10.0 cc.**	154 min.
Menthol	**0.5 Gm.**	7 gr.
Eucalyptol	**0.5 cc.**	8 min.
Methyl Salicylate	**0.5 cc.**	8 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix the diluted hydrochloric acid with 800 cc. [25 fl. oz. 288 min.] of cold distilled water and dissolve the pepsin in this liquid by gentle stirring; then add the glycerin. Dissolve the menthol, eucalyptol, and methyl salicylate in the alcohol, add to the first solution, then add sufficient distilled water to make the product measure 1000 cc. [2 pints]. Set aside for twenty-four hours, and filter.

NOTE—Pepsin solutions are reduced in proteolytic activity by agitation and storage, particularly at or above normal room temperature. To insure the dispensing of this Solution at standard strength, it is strongly recommended that the quantity of pepsin in the formula be increased to 65 Gm. or 75 Gm. to allow for such loss in activity, and that the Solution be stored in a cool place.

Antiseptic Solution of Pepsin is a transparent, brownish-yellow liquid having an aromatic, eucalyptus-like odor, and an acid, pleasant, aromatic taste, and an acid reaction.

One-tenth cc. of this Solution will digest 10 Gm. of egg albumen, carrying out the test according to details of the U. S. P. X assay under *Pepsinum*, page 1173.

Approximate alcohol content, by volume, 0.9 per cent.

Uses—This solution is used as a dressing for old wounds causing the digestion of extraneous tissue and promoting healing. It is not used internally.

LIQUOR PEPSINI AROMATICUS. N. F. Aromatic Solution of Pepsin

[Liq. Pepsin. Arom.]

	Metric	Alternative
Pepsin (see note below)	**17.50 Gm.**	255 gr.
Diluted Hydrochloric Acid	**5.00 cc.**	77 min.
Glycerin	**250.00 cc.**	8 fl. oz.
Alcohol	**35.00 cc.**	1 fl. oz. 58 min.
Oil of Cinnamon	**0.25 cc.**	4 min.
Oil of Pimenta	**0.25 cc.**	4 min.
Oil of Clove	**0.50 cc.**	8 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Mix the diluted hydrochloric acid with 700 cc. [22 fl. oz. 192 min.] of cold distilled water and dissolve the pepsin in this liquid by gentle stirring; then add the glycerin. Dissolve the oils in the alcohol and add to the aqueous solution, then add sufficient distilled water to make the product measure 1000 cc. [2 pints] and mix thoroughly by gentle agitation. Set the mixture aside for twenty-four hours, then filter.

NOTE—Pepsin solutions are reduced in proteolytic activity by agitation and storage, particularly at or above normal room temperature. To insure the dispensing of this Solution at standard strength it is strongly recommended that the quantity of pepsin directed in the formula be increased to 25 Gm. to allow for such loss in activity, and that the solution be stored in a cool place.

Aromatic Solution of Pepsin is a pale yellow, transparent liquid, with a pleasant, aromatic, cinnamon-like odor, a strong, sweet, aromatic taste and an acid reaction.

One-fourth cc. of the Solution digests 10 Gm. of egg albumen, carrying out the test according to the details of the U. S. P. X assay under *Pepsinum*.

Approximate alcohol content, by volume, 3 per cent.

Uses—It is used as a digestant; the dose is two fluidrachms (8 cc.), representing about two grains of pepsin.

PANCREATINUM. U.S. Pancreatin

[Pancreat.]

Pancreatin is a substance containing enzymes, principally amylopsin, trypsin, and steapsin, obtained from the fresh pancreas of the hog, *Sus scrofa* var. *domesticus* Gray (Fam. *Suidæ*) or of the ox, *Bos taurus* Linné (Fam. *Bovidæ*).

It converts not less than 25 times its weight of starch into soluble carbohydrates and not less than 25 times its weight of casein into proteoses. Pancreatin of a higher digestive power may be brought to this standard by admixture with lactose.

Preparation—Pancreatin is made by cutting the fresh pancreas into small pieces, kneading thoroughly with water, straining the liquid, and then filtering; an equal volume of alcohol is added to the filtrate and the precipitate is dried and powdered. The constituent *amylopsin* converts starch into maltose and forms small amounts of dextrose. Slight acidity checks this reaction and destroys the enzyme. *Trypsin* acts upon proteins and nucleoproteins, changing them into peptones and polypeptids. An excess of mineral acid soon decomposes it, although it keeps fairly well in 25 to 50 per cent alcohol and best in 50 per cent glycerin. Both ferments are most active at 40° C. in a slightly alkaline medium.

Description and Physical Properties—A cream colored, amorphous powder, having a faint, characteristic, but not offensive odor.

Pancreatin is slowly and incompletely soluble in water; insoluble in alcohol.

Pancreatin changes proteins into proteoses and derived substances, and converts starch into dextrins and sugars. Its greatest activities are in neutral or faintly alkaline media; more than traces of mineral acids or large amounts of alkali hydroxides render it inert. An excess of alkali carbonates also inhibits its action.

Tests for Purity—Introduce 2 Gm. of Pancreatin into a flask of about 50 cc. capacity, add 20 cc. of ether, stopper, and set it aside for several hours, mixing by rotating at frequent intervals. Decant the supernatant ether by means of a guiding rod into a plain filter of about 7 cm. diameter, previously moistened with ether, and collect the filtrate in a tared beaker. To the residue remaining in the flask, add a further portion of 10 cc. of ether, proceeding as directed before, then a third portion of 10 cc. of ether, and transfer the ether and the remainder of the pancreatin to the filter. Allow to drain, evaporate the ether spontaneously, and dry the beaker and residue to constant weight at 100° C.: the residue weighs not more than 0.06 Gm. (*fat*).

Assay for Starch Digestive Power—Shake 10 Gm. or more of powdered potato starch with about 10 times its weight of cold distilled water, and, after draining the mixture on a filter, wash it with the same quantity of distilled water. Place the washed starch at once in an air bath, and maintain a temperature of about 50° C. until the starch is sensibly dry. Reduce it to a fine powder, and place it in a well-stoppered bottle. Determine the percentage of water remaining in the starch by drying about 0.5 Gm. of it in an air bath, gradually raising the temperature to 120° C. and maintaining it at that temperature for four hours. Of the washed and partially dried starch, mix a quantity equivalent to 7.5 Gm. of dry starch in a 400 cc. beaker with 10 cc. of cold distilled water, add 190 cc. of boiling distilled water, and boil the mixture gently with constant stirring for five minutes or until a translucent, uniform paste is obtained. Replace the water lost by evaporation, and cool the paste to 40° C. in a water bath previously adjusted to this temperature and add a

solution of 0.3 Gm. of Pancreatin in 10 cc. of distilled water, just previously made at 40° C. Mix well, and maintain the same temperature for exactly five minutes, when a thin, nearly clear liquid is produced. At once add 0.1 cc. of this liquid to a previously made mixture of 0.2 cc. of tenth-normal iodine and 60 cc. of distilled water. No blue, red or violet color is produced.

Assay for Casein Digestive Power—Place 0.1 Gm. of finely powdered casein in a 50 cc. volumetric flask, add 30 cc. of distilled water, and shake well to bring the casein into suspension. Add exactly 1 cc. of tenth-normal sodium hydroxide, and heat the mixture at 40° C. until the casein is completely dissolved which should not require more than thirty minutes. Cool, add sufficient distilled water to make 50 cc., and mix well. Dissolve 0.1 Gm. of Pancreatin in 500 cc. of distilled water. Mix 1 cc. of glacial acetic acid with 9 cc. of distilled water and 10 cc. of alcohol. Place 5 cc. of the casein solution in a test tube, add to it 2 cc. of the well-shaken Pancreatin solution and 3 cc. of distilled water, and mix by gentle agitation. Immediately immerse the test tube in a water bath at 40° C., and keep it at this temperature for one hour. Then remove from the bath, and add 3 drops of the acetic acid mixture. No precipitate is produced.

Preserve in well-closed containers.

N. F. Preparations—Liquor Pancreatini; Pulvis Pancreatini Compositus.

Uses—Pancreatin is used to aid digestion. Pepsin and pancreatin are not active in the same media. What is suitable for one will destroy the other, hence, it is illogical to give them in the same combination, as was done in the older compound digestive elixirs, which, however, are still in demand as physicians insist upon prescribing them however illogical their constitution. It should not be given in combination with acids; weak alkalies assist its action. The dose is from five to ten grains (0.3 to 0.6 Gm.).

LIQUOR PANCREATINI. N. F. Solution of Pancreatin

[**Liq. Pancreat.**—Liquor Pancreaticus, Pancreatic Solution]

	Metric	Alternative
Pancreatin	**17.5 Gm.**	255 gr.
Sodium Bicarbonate	**50.0 Gm.**	1 oz. av. 293 gr.
Glycerin	**250.0 cc.**	8 fl. oz.
Compound Spirit of Cardamom	**3.5 cc.**	54 min.
Alcohol	**65.0 cc.**	2 fl. oz. 38 min.
Magnesium Carbonate	**8.0 Gm.**	117 gr.
Sodium Chloride	**5.0 Gm.**	73 gr.
Chloroform	**2.0 cc.**	31 min.
Distilled Water, a sufficient quantity,		
To make	**1000 cc.**	2 pints

Triturate the pancreatin, sodium chloride, and the sodium bicarbonate gradually with 625 cc. [20 fl. oz.] of distilled water; add the alcohol, compound spirit of cardamom and magnesium carbonate; mix them thoroughly by shaking, and pour the mixture upon a wetted filter, returning the first portions of the filtrate until it passes through clear. Wash the filter with sufficient distilled water to obtain 748 cc. [23 fl. oz. 449 min.] of filtrate. To this add the chloroform and glycerin and mix.

Solution of Pancreatin is a pale yellow, transparent liquid, with an aromatic odor, and a saline, sweet, aromatic taste and an alkaline reaction.

Assay—Add 5 cc. of Solution of Pancreatin to 25 cc. of tepid, distilled water, contained in a flask, then add 100 cc. of cow's milk which has previously been heated to 40° C. Keep the temperature at 40° C. for 30 minutes. At the end of this time the milk is so completely peptonized that on diluting 3 cc. with 9 cc. of distilled water, then mixing with 3 cc. of acetic acid, no coagulation occurs.

Dose—1 fluidrachm (4 cc.).

PULVIS PANCREATINI COMPOSITUS. N. F. Compound Pancreatin Powder

The formula for this powder, frequently called *Peptonizing Powder*, and used in the preparation of a predigested milk, will be found on page 483.

Unofficial Digestive Enzymes

The following is an abstract of a discussion on enzymes and their action, taken from the 1925 N. N. R. with permission:

In medicine, enzymes or digestive ferments are used internally for the purpose of supplementing or replacing deficient or about normal alimentary secretions; outside of the body for the digestion of food prior to its administration and locally for the softening of dead tissues or the solution of false membranes.

Most digestive enzyme preparations used in medicine are obtained from the digestive glands.

The *peptic enzymes* digest proteins and curdle milk under appropriate conditions. They are used frequently to coagulate milk in the preparations of junket, whey, etc. They are also used to favor the digestion of proteins in the stomach. For this purpose they act efficiently only in the presence of hydrochloric or other suitable acids.

The *tryptic enzymes* are commonly prepared from pancreatic tissue. Dried pancreas and pancreatic extracts are generally supposed to contain all the enzymes characteristic of the gland. They are extremely uncertain in their activity, however. The starch-digesting action (amylopsin or diastase content) is generally the most satisfactory, although it varies greatly. The protein digestion (trypsin content) is so slight, with many samples, as to be practically negligible and the fat-digesting lipase or steapsin, because of its instability, is practically absent from all. Most pancreatic preparations are very unstable, even when undiluted; and after dilution, they often deteriorate within a day. The so-called isolated ferments are more or less purified extracts.

Trypsin acts in a slightly alkaline medium on proteins converting them into peptones and polypeptids, and carries the cleavage to the point where these are split down into the amino acids. It acts best at a temperature of about 40° C. and in a feebly alkaline medium not exceeding a strength of 1 per cent of sodium bicarbonate. Under ordinary conditions trypsin is largely destroyed in the stomach and there is very little reason to expect any action from it in the intestines when it is given by the mouth.

Trypsin has been applied locally for the solution of diphtheric and other false membranes.

In aqueous solution, the enzyme is uncertain in action and aqueous solutions for assay or for any application of the enzymes are to be prepared only at the moment required. It should not be kept for any length of time in any solution of an alkaline or acid reaction or it will become inactive. It is readily soluble in alcohol of from 25 to 50 per cent strength, and in such menstruum is relatively stable. It is most stable in 50 per cent glycerin solution.

Trypsin in any menstruum in which this enzyme is stable, exerts (in vitro) a destructive influence on other enzymes, whether those normally associated with trypsin—amylopsin, for instance—or placed in contact with it in solution, as, for instance, pepsin.

Determination of Tryptic Value by the Fuld-Gross method, which is more definite than the U. S. P. assay and is easily carried out:

It depends on the digestion of a sodium caseinate solution to the point at which it no longer gives a precipitate with dilute acetic acid. A casein solution of 0.2 per cent strength is prepared by dissolving 100 mgm. of pure casein in 2 cc. of twentieth-normal sodium hydroxide, by aid of very gentle heat and diluting to 50 cc. A dilute acid is prepared with 50 cc. of alcohol, 45 cc. of water and 5 cc. of glacial acetic acid.

The trypsin solution is made by dissolving in the proportion of 20 mgm. to 50 cc. of water.

Six portions of the casein solution of 5 cc. each containing 10 mgm. of casein, are measured out, and diminishing portions of the trypsin solution are transferred to test tubes, but always made up to 5 cc. For the milligram of casein, the weights of trypsin may be taken as follows: 2 mgm., 1.3 mgm., 0.8 mgm., 0.5 mgm., 0.3 mgm., and 0.1 mgm. The series of test tubes containing casein and trypsin, so charged, are incubated one hour at 40° C. and then withdrawn from the bath. To each tube, 3 drops of the dilute acetic acid is added. If full digestion has taken place, the acid fails to produce a precipitate. The last tube in which no precipitate is formed gives an approximate measure of the digesting power of the enzyme preparation, which may be sufficient.

A closer result may be obtained by making up a new series of enzyme solutions of just one-tenth the strength of the last. These are to be incubated with the casein solution in the same way, the final test being made as before.

When tested in this manner, 1 part of trypsin should digest at least 75 parts of casein.

As originally suggested, this Fuld-Gross test employed a much weaker casein solution; but there is a distinct advantage in using as much casein as here recommended, and any enzyme of reasonable strength should react with this weight of casein. The weak casein solutions are useful in testing very weak tryptic solutions, in scientific investigations mainly.

Amylopsin, the starch-digesting enzyme of the pancreas, converts starch into maltose and forms a small amount of dextrose. It acts best at a temperature of about 40° C. and in a slightly alkaline medium. It is very sensitive to free acids. Even slight degrees of acidity check the action and destroy the ferment. Enzymes comparable to amylopsin (amylases) are obtained from the salivary glands and from certain molds.

Amylopsin and other amylases are rarely used for the digestion of starch in the preparation of food, because malt diastase is preferable. It is not likely to be of service to secure the digestion of starch in the intestine because it is likely to be destroyed in the stomach.

Determination of Amylolytic Value—(For diastases, malt and pancreas preparations.) The A.M.A. Council on Pharmacy and Chemistry does not endorse the methods which are based on the time of change from blue to red given by iodine, or the time of disappearance of all color, but instead it has adopted as the standard the amount of starch that can be converted to colorless end-point in ten minutes, by a given weight of the product working according to the details described in the *J. A. M. A.* 51: 140 [July 11] 1908, and *Jour. Chem. Soc.* 30: 798, 1908.

Succus Citri et Pepsinum, N. F. IV—*Lime Juice and Pepsin*—Add 400 cc. of glycerite of pepsin to 600 cc. of lime juice and filter the mixture. This preparation should not be dispensed unless it has been recently prepared.

Uses—It is a pleasantly flavored digestant; dose, two fluidrachms (8 cc.).

Elixir of Enzymes, N. N. R.—A solution containing pepsin and rennet in a menstruum containing 15 per cent of alcohol.

Elixirs of enzymes is a light yellow, palatable, liquid preparation. One part digests about 70 parts of coagulated egg albumen in two and one-half hours. Eight cc. (2 fluidrachms) coagulates 500 cc. (1 pint) of milk in a few minutes.

Uses—This elixir is claimed to be useful as an aid to digestion and as a vehicle for various drugs. Dose, from one to two fluidrachms (4 to 8 cc.) with meals; for children in proportion.

Manufactured by Armour and Company.

Enzymol, N. N. R.—An extract prepared from the fresh animal stomach, said to contain the activated gastric enzyme in association with the soluble constituents with which the pro-enzyme is naturally associated. It is free from alcohol, contains a trace of thymol, and has an acidity due to combined hydrochloric acid equivalent to 0.26 to 0.3 per cent of actual hydrochloric acid. It is adjusted to a definite proteolytic power by the U. S. P. assay method for pepsin, and contains 25 per cent of glycerin by weight.

Enzymol is a light straw-colored fluid.

Uses—Enzymol is said to be useful as an application to old sores, ulcers and slow-healing wounds. It is said to correct offensive odors, to exert a solvent action on pus and sloughing and necrotic tissue, and to impart a healing stimulus. It is said to have been effective in cases which have long remained unhealed and have resisted treatment. Dose: It is made ready for use by the addition of from one-half to one or two volumes of water; for the solution of necrotic and carious bone, and in some large abscess cavities, it is advised

that the preparation be diluted with two volumes of 0.2 per cent solution of hydrochloric acid. A small vial, containing diluted hydrochloric acid and a pipette, for measuring, accompany the package of enzymol.

Manufactured by Fairchild Bros. and Foster.

Essence of Pepsin-Fairchild, N. N. R.—An aromatized, faintly acid liquid obtained by direct extractions from the pig stomach glands, and from the lining membrane of the calf stomach, and containing the entire soluble constituents of the fresh stomach glands—the proteolytic and milk-curdling enzymes, coagulable nucleoproteids, organic and inorganic extractives—and 18.5 per cent alcohol.

Uses—Essence of pepsin-Fairchild is claimed by the manufacturers to be of value in disorders of stomach digestion, as a vehicle for the administration of drugs, and in the preparation of whey and other milk food for the infant and invalid. Dose, one fluidrachm (4 cc.) or more.

Manufactured by Fairchild Bros. and Foster.

Gastron, N. N. R.—A solution of the gastric tissue juice obtained by direct extraction from the mucosa of the fresh stomach of the pig and containing the activated principles of the gastric cells, the enzymes and the associated organic and inorganic constituents in an acid, aromatized menstruum containing 25 per cent glycerin by weight. It has an acidity corresponding approximately to 0.25 per cent absolute hydrochloric acid, and 1 cc. dissolves 200 Gm. coagulated egg albumen under standard conditions.

Gastron is a viscid, slightly opaque, straw-colored fluid. Heat and strong alcohol cause coagulation of gastron.

Uses—Gastron is claimed to exhibit the characteristic enzyme properties of gastric secretion. It is designed to present in stable form a complete gastric gland extract for use in disorders of gastric functions Dose, from one to two fluidrachms (4 to 8 cc.) diluted with a little cold water or with acidulated water. It may be administered before, in divided doses during, or after meals.

Manufactured by Fairchild Bros. and Foster.

Trypsin, N. N. R.—The proteolytic enzyme of the pancreas, separated to a considerable extent from the other constituents of the gland.

Uses—See discussion of tryptic enzymes in preceding general article, Digestive Enzymes.

Trypsin-Armour—It is stated that Trypsin-Armour is standardized so that 1 part digests at least 100 parts of casein according to the Fuld-Gross method. Trypsin-Armour is prepared from the fresh pancreas of hogs with the view of retaining the proteolytic ferment in an especially active condition. It has been activated by enterokinase.

It is a light yellow powder, possessing a faint odor, and a meat-like taste. It is not completely soluble in water at once, but dissolves almost entirely in time. Dose: Trypsin-Armour is applied locally by means of a brush or as a spray. About 6 grains (0.4 Gm.) is mixed with 2 grains (0.125 Gm.) sodium bicarbonate and triturated in a mortar while 1 or 2 drachms of distilled water is added. The mixture is then warmed to from 38° to 40.6° C. and applied immediately. The application may be repeated several times an hour if necessary, a fresh solution being made before each application. The internal dose is two grains (0.125 Gm.), or more, three times daily. It should not be used for hypodermic injection.

Manufactured by Armour and Company.

Trypsin-Fairchild—When tested by the Fuld-Gross method it is said that trypsin-Fairchild converts 200 times its weight of casein to the standard end-point. Trypsin-Fairchild, is a fine dry powder, in which form the enzyme is permanent when protected from moisture. It is slowly but not completely soluble in water.

Trypsin-Fairchild has from four to five times the strength of pancreatin-U. S. P. The tryptic power of Fairchild's trypsin by the method proposed by Sir William Roberts is 10,000 units. Dose: Trypsin-Fairchild may be given in doses of 1 grain (equal to from 4 to 5 grains pancreatin-U. S. P.) and upward, best in a capsule with some diluent as milk sugar, and if indicated, with sodium bicarbonate. It is locally applied in solution or after trituration of the trypsin with some appropriate diffusible powder.

Manufactured by Fairchild Bros. and Foster.

Diazyme Essence, N. N. R.—A liquid said to contain the amylolytic enzyme of the pancreas, devoid of trypsin and lipase in a menstruum containing 18.5 per cent of alcohol by volume.

Diazyme essence is an amber fluid of aromatic taste and odor and slightly acid reaction.

One cubic centimeter will convert 125 Gm. of pure starch mucilage, containing 5 Gm. of dry starch, the mixture being kept at 40° C., so that the solution will cease to give a color reaction with iodine at the end of ten minutes.

Uses—Diazyme is capable of digesting starch and is claimed to be useful in compensating deficient salivary and pancreatic action in the digestion of starch. Dose, from one to two fluidrachms (4 to 8 cc.).

Manufactured by Fairchild Bros. and Foster.

Diazyme Glycerole, N. N. R.—A liquid said to contain the amylolytic enzyme of the pancreas, devoid of trypsin and lipase, in a menstruum containing about 60 per cent of glycerin by volume.

Diazyme glycerole is a dense, amber fluid, of agreeable taste and odor, and of slightly acid reaction.

At 40° C., 1 cc. will convert 125 Gm. of pure starch mucilage containing 5 Gm. of dry starch, so that the solution will cease to give a color reaction with iodine in ten minutes.

Uses and Dose—The same as those of diazyme essence.

Manufactured by Fairchild Bros. and Foster.

Holadin, N. N. R.—*Extractum Pancreaticum Integrum*—An extract of the entire pancreas containing all the constituents of the gland and exhibiting great potency in respect to the several known enzymes trypsin, amylopsin, lipase and the milk-curdling ferment.

Holadin is a grayish-white powder, slightly aromatized, somewhat hygroscopic, freely but not wholly soluble in water.

Uses—Holadin has power to digest starch and protein and to split fats. It is claimed to be useful in various diseases in which digestion of food is imperfect. Dose, from three to nine grains (0.2 to 0.6 Gm.), three hours after meals and at bedtime.

Manufactured by Fairchild Bros. and Foster.

Panase, N. N. R.—A combination of the digestive enzymes of the pancreas derived from the pancreatic gland of the pig.

Panase is a light, yellowish-white powder having a slight odor and somewhat mucilaginous taste. It is not entirely soluble in water or glycerin, owing to the small amount of protein present. Filtration of its solution, however, does not impair its digestive activity.

Uses—Panase is intended to be used in cases in which it is believed that the enzymes of the pancreas are deficient or in which it is desired to hasten the digestion of starch. Dose, two grains (0.13 Gm.) or more.

It is incompatible with strong alcohol, acids, alkalies and other substances which destroy the activity of enzymes.

Manufactured by Frederick Stearns and Company.

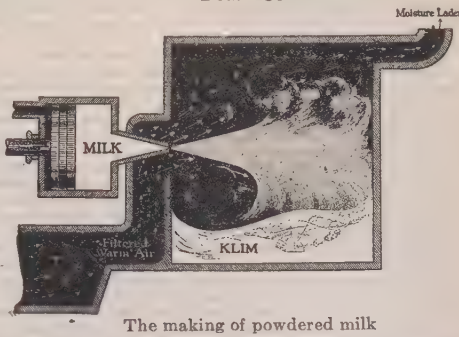
LAC VACCINUM. N. F. Cow's Milk

The fresh unpasteurized milk of the domestic cow, *Bos taurus* Linné (Fam. *Bovidæ*), without modification, and complying with the legal standards of the State or community in which it is sold.

N. F. Preparation—Lac Fermentatum.

Uses—Milk is recognized by the N. F. solely for the preparation of fermented milk (see page 1182). Milk is marketed and sold in most states under rigid regulations concerning the health of the cows, the transportation conditions for the milk, and the amounts of fat and total solids. The minimum butter fat content of milk as regulated by law in most communities is 3.25 per cent, and the minimum content of total solids is 11.50 per cent. Preservatives and coloring matters are prohibited in milk by all food laws. It is also largely sold in cans as *condensed milk*, a product obtained by evaporating whole milk or partially skimmed milk in vacuum and preserving it with cane sugar, and also as *evaporated milk*, obtained by evaporating whole milk without adding sugar and preserving it by sterilization. Another commercial form is known as *desiccated milk* or *milk powder*. In preparing powdered milk the original milk is put into a cylinder and forced out through tiny orifices by great pressure, so that it comes out in the form of a cloud or mist, just exactly as from a huge atomizer. This milk spray enters a chamber or room through which are blowing strong currents of filtered warm air. The milk mist is whirled about the chamber just as the wind blows clouds of snow or fog.

FIG. 439



The making of powdered milk

This warm air immediately absorbs the moisture in the milk and the solid portion falls like snow in drifts of powdered milk. This moisture-laden air passes out through muslin screens which prevent any of the powdered milk from escaping. Fig. 439 illustrates the process. One of the extensively used powdered milks is sold under the trade name "Klim". It is largely used by bakers and confectioners and in the manufacture of ice cream, and is an excellent emulsifying agent for cod liver oil.

Unofficial Lactic Acid-Producing Organisms and Preparations

The following abstract, taken from the 1925 N. N. R., is a valuable review of the therapeutics and of the products developed about the use of lactic acid-producing organisms:

Milk soured by acid-producing organisms more or less common to ordinary commercial milk, or by certain types or species intentionally added with or without the association of alcohol-producing yeast (*kefir, kumyss*), has been used as a food for centuries. This practice is due to the fact that the products are palatable to many, or to the belief among the laity, as well as physicians, that they are beneficial in the correction of certain disorders of the gastro-intestinal tract. The theories of Metchnikoff gave a great stimulus to the employment of fermented milks. His theories of "intestinal putrefaction" were in part that the products of putrefaction, occurring chiefly in the large intestine, were absorbed and that their action on the walls of the blood vessels produced arteriosclerosis and premature senility. He also advanced the theory that the growth of proteolytic bacteria which elaborated these poisons could be modified or prevented by the implantation in the intestine of lactic acid-producing bacteria such as *Bacillus bulgaricus*.

During recent years, reports have been published which indicate that the growth in the intestinal canal of the normally present *Bacillus acidophilus* may be increased so as to make it the predominating organism, by the administration of lactose (sugar of milk), by milk, inoculated and fermented with *Bacillus acidophilus*, or by the administration of viable cultures of *Bacillus acidophilus* in conjunction with lactose. Because of these reports, *Bacillus acidophilus* products have come into use in this country. While no one subscribes seriously today to the original theories of Metchnikoff, there are many who believe that the regulation of types of bacteria and of bacterial activities in the intestine is of much importance. Since *Bacillus acidophilus* and its very close neighbor, *Bacillus bifidus* are common and, as a rule, the predominating types in the intestines of breast-fed infants and furthermore, since extensive experiments have been made which show these organisms to be of a strictly non-putrefactive and apparently harmless nature, many give added weight to the claims made for their therapeutic value.

There is evidence that the administration of sour milk is at times beneficial, particularly in pediatrics, in which field fermented milks have found a wide application. Sour milk and sour milk products are used in vomiting, and in acute diarrhea as well as in chronic disturbances of the gastro-intestinal tract. It is not known at present why sour milks are of value, but a wide clinical observation gives a basis for the opinion that, for certain types of gastric and intestinal disturbances, fermented milk accomplishes more than sweet milk with a similar fat, sugar and protein content. No one, of course, will deny the great value of milk, whether sweet or soured by the so-called "lactic acid-producing bacteria", as a growth-promoting and energy yielding food.

Recent observations seem to indicate that *Bacillus bulgaricus* cannot be implanted or made to proliferate in the intestine even when administered in large numbers. Much doubt is cast, therefore, on any alleged physiologic action of this organism in the intestine. For this reason, and because *Bacillus acidophilus*,

according to reports, can be successfully implanted, the preference is now given by many to lactic acid bacillus cultures prepared with *Bacillus acidophilus*.

There is little, if indeed any, satisfactory proof that liquid cultures or aqueous suspensions of lactic acid-producing organisms are of real value as local applications of mucous membranes or in arresting putrefaction or suppuration in wounds, abscesses and sinuses. In such conditions, their use appears to be still in the experimental stage.

Sour milk has generally been administered in the form of buttermilk (artificially or naturally soured with *Streptococcus lacticus* predominating) or milk soured with lactic acid-producing organisms such as *Streptococcus lacticus* or *Bacillus bulgaricus* or fermented milks (kefir, kumyss).

To these may now be added the so-called *Bacillus acidophilus* milk which is prepared by the inoculation of milk which has been previously sterilized or heated for about an hour, at or near boiling temperature, with a pure starter made by inoculating pressure-sterilized milk with viable *B. acidophilus* and incubating at from 35° to 37° C. for from twenty to twenty-four hours. On the completion of proper ripening, which should take place within from twenty to twenty-four hours at from 35° to 37° C., a product is obtained which is slightly sour to the taste and has a characteristic odor not very unlike ordinary pure buttermilk. There is a slight separation of whey, but, on thoroughly mixing, the product has a uniform creamy consistency. *Bacillus acidophilus* milk is produced in various laboratories and dairies, though in many instances with partial success only. It may be made from fresh skim milk, whole milk, or from skim milk to which varying amounts of cream have been added. In all milk culture work, mass inoculation with the use of a sterile pipette is necessary. The preparation of uniform, pure Bacillus acidophilus milk requires adequate facilities, the aid of a trained technician, and close adherence to instructions.

Bacillus acidophilus and *Bacillus bulgaricus* belong to a group of bacteria, the lactobacillus group, which has not until recently received much scientific attention, but which is widely distributed in nature. Both are long and fairly slender bacilli, which at times have a tendency to filament formation. They are preferably micro-aerophilic, but grow well under ordinary aerobic conditions. They are gram-positive, though in old cultures individual rods or filaments may at times fail to retain the stain. In spite of claims to the contrary branching may be observed only occasionally, the branched forms resembling more or less another organism of this group, *Bacillus bifidus*, which quite commonly reveals branching.

Both organisms require carbohydrates for their successful cultivation. Glucose, galactose and lactose broth are fairly suitable, but much less favorable than milk or milk whey. Milk is a particularly good medium for the preservation of viability. For isolation purposes and for colony study, whey-agar and galactose or lactose-agar may be used to advantage.

Bacillus acidophilus and *Bacillus bulgaricus* have very many points in common. They differ, however, in the following respects: 1. *B. acidophilus* is relatively slow in acid production in milk, the amount of acid produced during twenty-four hours' incubation, rarely exceeding 1 per cent, whereas milk cultures of *B. bulgaricus* may attain an acidity of 3 per cent in the same period of time. 2. Except in the case of so-called border strains, *B. acidophilus* attacks maltose with acid production, while *B. bulgaricus* is unable to do so. 3. *B. acidophilus* is of intestinal origin, and, therefore, can adapt itself to intestinal conditions. Whereas *B. bulgaricus* is an ordinary saprophyte and is unable to develop or even to maintain itself in the digestive tract.

The group of lactobacilli is probably one large group which consists of many varieties in the same way as the *B. coli* and the streptococcus groups. Certain members of the lactobacillus group (acidophilus and bifidus types) are found in the feces of man and animals. Others (bulgaricus type) are very common in cow barns and in dairies, and in various dairy products. The well-known *Bacillus bulgaricus* is the predominating organism in the oriental sour milk products and it is to this type of the lactobacillus group that these products in a large measure owe their characteristic properties. All cultures of *B. acidophilus* and *B. bulgaricus* deteriorate with age, and, therefore, should be used soon after they are prepared. While viability appears to be preserved best in milk cultures, even these should have a brief expiration limit, and should be kept at relatively low temperature. Experience has shown that *B. bulgaricus* and *B. acidophilus* are short-lived in so-called tablets and powders. Bacteriologic examination of such powders and tablets and of various broth cultures, has often shown them to contain, at the most, but few living aciduric organisms. All lactic-acid ferment preparations should be kept at or near ice-chest temperature and marked with an expiration date.

Bacillus Acidophilus Milk-Lederle, N. N. R.—Whole milk cultured with *Bacillus acidophilus*. It contains not less than fifty million of viable organisms (*B. acidophilus*) per cubic centimeter.

Whole milk is sterilized at 100° C. for 2 hours, cooled at 37° C. and inoculated with a twenty-four hour culture of *B. acidophilus*. After inoculation, the milk is kept at 37° C. for from 20 to 24 hours, until an acidity is reached so that 10 cc. will require for neutralization 11 cc. of tenth-normal sodium hydroxide using phenolphthalein T.S. as indicator. The product is then cooled to 5° C., agitated until homogeneous and transferred to 200 cc. bottles, which are closed with seals. The strain of *B. acidophilus* used is one isolated by Rettger. To insure its adaptability to intestinal implantation, the bacillus is freshly isolated from intestinal contents as frequently as is necessary.

Uses—During recent years reports have been published which indicate that the growth in the intestinal canal of the normally present *Bacillus acidophilus* may be increased so as to make it the predominating organism by the administration of milk inoculated with *B. acidophilus* by the administration of viable cultures of the *Bacillus acidophilus* in conjunction with lactose, or by the administration of lactose alone. The therapeutic value of the administration of cultures of *B. acidophilus* is still in the experimental stage. Dose, for adults, 1000 cc. of bacillus acidophilus milk-Lederle per day increased or decreased to meet requirements. When employed in infant feeding, it may be diluted with boiled water. It must be kept in a cool place and should be used prior to the date stamped on the package.

Manufactured by Lederle Antitoxin Laboratories.

Bacillus Bulgaricus-Squibb, N. N. R.—A pure culture of *Bacillus bulgaricus*, marketed in twelve tubes each containing 12 cc. The culture is grown on whey.

Uses—See preceding general article. Dose, the contents of from one to three tubes daily, one-half hour after meals or before retiring. These tubes should be kept in a cold place and are not guaranteed beyond the date stamped on the package.

Manufactured by E. R. Squibb and Sons.

B. B. Culture, N. N. R.—A pure culture of *Bacillus bulgaricus*, marketed in bottles, containing about 90 cc. (3 fluidounces).

Uses—B. B. culture is adapted both for internal and external use. Dose, from one to two fluidrachms (4 to 8 cc.) three times a day in sweetened water before meals. For babies of any age, 1 teaspoonful every three hours. The date of issue and of expiration is stated on each bottle.

Manufactured by the B. B. Culture Laboratory, Inc.

Bulgara Tablets-H. W. & D, N. N. R.—Tablets containing a practically pure culture of *Bacillus bulgaricus*.

Bulgara tablets consist of the slowly dried cultures mixed with milk sugar and starch, each tablet weighing 5 grains (0.3 gm.) and containing a sufficient number of viable organisms to effect the souring of a pint of sterile milk in less than twenty hours.

Uses—See preceding general article. Dose, one or two tablets before or after meals. The diet should contain a sufficiency of sugar.

Bulgara tablets are marketed in tubes, each containing fifty tablets, with an expiration date stamped on the label.

Manufactured by Hynson, Westcott and Dunning.

Bulgarian Bacillus Liquid-Mulford, N. N. R.—A pure culture in tubes of *Bacillus bulgaricus*.

Uses—See preceding general article. Dose, one tube of the culture in three tablespoonfuls of water, containing a lump of sugar, or in a half or a full glass of milk. This dose should be repeated morning and evening after meals. The culture is marketed in packages of twenty tubes. The tubes must be kept in a cold place and should not be used after the date stamped on the package.

Manufactured by the H. K. Mulford Company.

Bulgarian Bacillus Tablets-Mulford, N. N. R.—Tablets containing a practically pure culture of *Bacillus bulgaricus*.

A culture of *Bacillus bulgaricus* grown on whey is mixed with starch, sugar and milk sugar, dried and compressed into tablets.

Uses—See preceding general article. Dose, for adults and children, one or two tablets after meals and at bedtime. For infants, 1 or 2 tablets with each feeding. An expiration date is stamped on the label.

Manufactured by the H. K. Mulford Company.

Cheplin's B. Acidophilus Milk, N. N. R.—A milk culture of *Bacillus acidophilus*. It contains not less than fifty million of viable organisms (*B. acidophilus*) per cubic centimeter at the time of sale.

Uses—See preceding general article. Dose, for adults, from 500 to 1000 cc. increased or decreased to meet individual requirements. When employed in infant feeding, it may be diluted with water which has been boiled and cooled, or with lime water in such proportions as the case may demand but it should be borne in mind that the product is made from skimmed milk and does not contain the growth promoting factor of milk fat; lactose (sugar of milk) should be added to restore the normal sugar content. Cheplin's *B. acidophilus* milk is marketed in bottles containing 400 cc. It must be kept on ice and should be consumed within the period of time stamped on the package (three weeks from date of preparation).

Manufactured by Cheplin Biological Laboratories, Inc.

Fresh skimmed cow's milk, standardized with 40 per cent. cream so that its final fat content in not less than one-half of 1 per cent is sterilized in one heating at 120° C. for 15 minutes. After cooling to at least 37° C., the milk is inoculated with a twenty-four hour culture of pure strains of *B. acidophilus* which have been grown by repeated transfers, sufficiently long in milk to develop rapidly and bring about proper coagulation of the casein. Viable milk cultures of the organisms are employed as the inoculum. After inoculation the milk is kept at 37° C. for from 20 to 24 hours until an acidity is reached so that 10 cubic centimeters will require for neutralization 10 cubic centimeters of tenth-normal sodium hydroxide solution, using phenolphthalein as indicator. The product is then agitated until completely homogeneous, transferred to 400 cc. bottles, which are closed with seals and cooled to 5° C. The strains of *B. acidophilus* used are isolated by Cheplin. To insure maximum therapeutic effects and colonization within the human alimentary canal, the organism is freshly isolated from human intestinal contents as frequently as is found necessary through actual feeding experiments.

Culture Bacillus Acidophilus-Medical Laboratories, Inc., N. N. R.—A broth culture of bacillus acidophilus in bottles containing about 120 cc. It contains from 250 to 500 million of viable organisms (*B. acidophilus*) per cubic centimeter at the time of sale.

Uses—See preceding article. Dose, from one to four fluidrachms (4 to 16 cc.) before meals. Each bottle bears an expiration date.

Manufactured by the Medical Laboratories Inc.

Culture of Bacillus Bulgaricus-Coleman, N. N. R.—A pure culture of *Bacillus bulgaricus* marketed in bottles, each bottle containing about 90 cc.

The culture is grown on a medium composed of whey broth containing dextrose.

Uses—This culture is stated to be suitable for all purposes for which *Bacillus bulgaricus* is used. See preceding general article. Dose, from four to twelve cc. in sweetened water or milk half an hour after meals. The culture must be kept in a cold place and should not be used after the time stamped on the bottle.

Manufactured by The Coleman Laboratories.

Culture of Bacillus Bulgaricus-Fairchild, N. N. R.—A pure culture in vials of *Bacillus bulgaricus*, each vial containing about 7 cc.

The bacilli are obtained by inoculation and incubation on Cohendy peptone-sugar-broth medium.

Uses—See preceding general article. Dose, internally, the contents of one vial is the usual daily dosage. The vials must be kept in a cold place and are not guaranteed beyond the date stamped on the package.

Manufactured by Fairchild Bros. and Foster.

Culture of the Bacillus Bulgaricus Lederle, N. N. R.—A pure culture of *Bacillus bulgaricus* in vials containing about 5 cc. each.

The culture is grown on one of the following mediums: calcium carbonate lactose broth, calcium carbonate dextrose broth, calcium carbonate Cohendy broth, or Cohendy broth.

The material for one of the above mentioned broths is sterilized for thirty minutes on three successive days and then placed in the incubator for at least forty-eight hours to determine its sterility before using. The material is then put into large flasks, inoculated from test tube cultures of the bacillus and incubated at 37° C. for from twenty-four to ninety-six hours. It is then tested to see that it is free from contaminating organisms.

The preparation is light yellow and has the odor and taste of the particular medium employed as its base.

Uses—See preceding general article. Dose, three or more vials daily. The culture must be kept in a cold place and should be used prior to the date stamped on the package.

Manufactured by Lederle Antitoxin Laboratories.

Galactenzyme Bouillon, N. N. R.—Suspension of Bacillus Bulgaricus-Abbott.—A pure culture in vials of *Bacillus bulgaricus* (Type A), each vial containing about 6 cc.

Cultures of a pure and virile strain of *Bacillus bulgaricus* (Type A) are grown in a specially prepared bouillon.

Uses—Galactenzyme bouillon is designed for internal administration in the treatment of intestinal fermentative diseases with the design of obtaining the growth of the bacilli in sufficient numbers in the alimentary tract to secure their characteristic action against putrefactive fermentation. It is also used for topical applications in nasal, aural, throat, urethral and other affections when the use of such a culture is indicated. Dose, the contents of one vial in a little sweetened water or milk, once or twice daily, perferably on an empty stomach. A small quantity of carbohydrate food should be included in the dietary.

It must be kept in a cold place and is not guaranteed beyond one year from the date stamped on the label.

Manufactured by The Abbott Laboratories.

Galactenzyme Tablets, N. N. R.—Tablets Bacillus Bulgaricus-Abbott—Tablets containing a practically pure culture of *Bacillus bulgaricus* (Type A).

Cultures of a pure and virile strain of *Bacillus bulgaricus* (Type A) are grown on sterilized milk. This milk culture of the organism is mixed with purified milk sugar. The mixture is dried in a stream of sterile, filtered air, at low temperature and the dried product compressed into tablets under aseptic conditions.

Uses—The same as for galactenzyme bouillon (see above). Dose, one, two or three tablets, three times a day, with meals. The diet should be regulated to meet the condition which may be present.

The tablets must be kept in a cold place and are not guaranteed beyond one year from the date stamped on the label.

Manufactured by The Abbott Laboratories.

Kefir Fungi, N. N. R.—A mixture of bacteria and yeasts capable of causing lactic acid fermentation of milk.

Kefir occurs in the form of white irregular, slightly round bodies, the size of a walnut with a very rough, furrowed surface, and of a tough gelatinous consistency. The substance contains *Sacchraromyces cerevisiæ* (Heyden), *Bacillus acidi-lactici* (Hueppe), *Dispora caucasico* (Kern). It acts on milk as follows: Fat, salt and water of the milk remain unaffected. The lactose is gradually decreased and the lactic acid increased. Alcohol is produced along with carbon dioxide; 10 per cent of the casein is converted into acid albumin and peptones, 10 per cent into hemialbumose and the rest loses its lime.

Uses—See preceding general article. Dose: Kefir kumyss may be prepared by adding active kefir grains to fresh cows' milk, kept at a temperature of from 21° to 27° C. until the effect of fermentation becomes apparent by the rising of the grains to the surface. The grains may then be strained off, and the milk, which then contains sufficient yeast cells to insure continuance of the fermentation, left to itself in well corked bottles.

Lactampoule, N. N. R.—A pure culture in ampuls of the *Bacillus bulgaricus*, each ampul containing about 12 cc.

The bacilli are obtained by the usual bacteriologic method, the growth of the bacilli on modified Cohendy peptone-sugar-broth medium.

Uses—See preceding general article. The ampuls must be kept in a cold place, and are not guaranteed beyond the date stamped on the package.

Manufactured by Fairchild Bros. and Foster.

Lactic Bacillary Tablets-Fairchild, N. N. R.—Tablets said to be made from a practically pure culture of *Bacillus bulgaricus*.

The culture of the Bulgarian bacillus is obtained by inoculation and incubation on modified Cohendy peptone-sugar-broth medium. This culture is reduced to a pulverulent form by the addition of sterile lactose, desiccated and compressed. The tablet is friable and contains an abundance of the true Bulgarian lactic acid bacterium.

Uses—See preceding general article. Dose, one or two tablets before or after meals. The tablets should be kept in a cold place and should not be used after the date given on the label.

Manufactured by Fairchild Bros. and Foster.

Vitalait Culture Bacillus Acidophilus, N. N. R.—A pure culture of *Bacillus acidophilus* in vials, each containing about 7 cc. It contains not less than three hundred million of viable organisms (*B. acidophilus*) per cubic centimeter at the time of sale.

Uses—See preceding article. Dose, the contents of one vial diluted with water, and followed by a quantity of sugar of milk is the usual daily dose. Each vial bears an expiration date.

Manufactured by The Vitalait Laboratory.

Vitalait Culture Bacillus Bulgaricus, N. N. R.—A pure culture of *Bacillus bulgaricus* marketed in vials.

The culture is grown in sterile skimmed milk, its incubation period being twenty-two hours. The average bacterial count of the finished culture is stated to be 200 million per cubic centimeter.

Uses—Condensed vitalait is designed for internal administration. See preceding general article. Dose, the contents of one vial in water or milk just before retiring is the usual daily dose. Each vial bears an expiration date.

Manufactured by The Vitalait Laboratory.

Vitalait Starter, N. N. R.—A culture in vials of *Bacillus bulgaricus* and *Streptococcus acidi-lactici* in symbiosis.

Bacillus bulgaricus and *Streptococcus acidi-lactici* are grown in skimmed milk without the addition of any chemical, and the culture sent out represents these organisms growing in this medium.

Uses—Vitalait starter is intended for the home preparation of fermented milk. Dose: The vitalait starter (sufficient to prepare from 1 to 3 quarts [1.1 to 3.4 liters] of fermented milk) is sent on request of the physician to the patient twice a week, with directions for the preparation of the fermented milk. Vitalait starter is sent within three hours of the time incubation is complete and must be used within five days from the date of mailing stamped on the label.

Manufactured by The Vitalait Laboratory.

LACTOSUM. U. S. Lactose

The description and tests for Milk Sugar will be found under the sugars on page 898.

LAC FERMENTATUM. N. F. Fermented Milk

[**Lac. Ferment.**—KUMYSS]

	Metric	Alternative
Cow's Milk (not pasteurized)	**1000 cc.**	**2 pints**
Compressed Yeast	**3 Gm.**	**44 gr.**
Sucrose	**35 Gm.**	**1 oz. av. 74 gr.**

Dissolve the sucrose in the milk, contained in a strong bottle, add the yeast, close the bottle securely and keep it at a temperature between 23° and 32° C. for six hours; then transfer it to a cool place, preferably a refrigerator.

The N. F. Fermented Milk is not similar in chemical composition or in properties to genuine Kumyss or similar lactic fermentation products as it is a preparation in which

sucrose is caused to undergo alcoholic fermentation by yeast. A discussion of the lactic acid producing organisms and preparations of these will be found under the unofficial products (see page 1179). Dose, eight fluidounces (250 cc.).

ACIDUM LACTICUM. U.S. Lactic Acid

[Acid. Lact.]

A mixture of lactic acid and lactic anhydrides equivalent to a total of not less than 85 per cent and not more than 90 per cent of $CH_3.CHOH.COOH$.

Preparation—Lactic acid may be made from sour milk, cheese, meat juice, and from some vegetable sources. Formerly it was obtained from cheese, and owing to its frequent occurrence in the decomposition of animal products it is considered here. It is now most conveniently prepared by treating cane sugar with sulphuric acid, so as to convert it into invert sugar, then adding solution of caustic soda and heating the mixture until it is transformed to such an extent that it no longer affects Fehling's solution, showing the absence of sugar. Sulphuric acid is added, and the sodium sulphate formed is crystallized out, an addition of alcohol causing the precipitation of the remainder. The alcoholic liquid contains impure lactic acid; one-half of it is heated and zinc carbonate added until effervescence ceases; the other half of the alcoholic liquid is now added and the whole allowed to cool. Zinc lactate crystallizes out; this, by treatment with hydrogen sulphide, yields zinc sulphide, lactic acid remaining in solution.

Description and Physical Properties—A colorless, or slightly yellow, nearly odorless, syrupy liquid. It absorbs moisture on exposure to air.

Lactic Acid is miscible with water, alcohol, and ether, but is insoluble in chloroform, petroleum benzin, and carbon disulphide.

Specific gravity: about 1.206 at 25° C.

Lactic Acid cannot be distilled without decomposition.

Tests for Identity—Lactic Acid is strongly acid to litmus paper and responds to the reactions for lactates, page 1183.

Tests for Purity—Ash: not more than 0.006 Gm. from 5 cc. of the Acid.

Ten cc. portions of an aqueous dilution of the acid (1 in 100) remain unaffected by the addition of 1 cc. of silver nitrate T.S. (*chloride*), or 1 cc. of barium chloride T.S. (*sulphate*).

The addition of 1 cc. of copper sulphate T.S. to 10 cc. of an aqueous dilution of the acid (1 in 20) causes no turbidity (*sarcolactic acid*).

No turbidity is produced on heating the Acid with an excess of calcium hydroxide T.S. (*citric, oxalic, phosphoric, or tartaric acid*).

Add a few drops of Lactic Acid to 10 cc. of hot alkaline cupric tartrate V.S.: no red precipitate is produced (*sugars*).

Carefully superimpose 5 cc. of Lactic Acid upon an equal volume of sulphuric acid in a clean test tube and keep the temperature at 15° C.: no dark color develops at the zone of contact of the two liquids upon standing for fifteen minutes (*readily carbonizable substances*).

An aqueous dilution of the Acid meets the requirements of the test for *heavy metals*, page 1519.

Assay—Add 50 cc. of normal sodium hydroxide to about 2.5 cc. of Lactic Acid, accurately weighed in a tared 250 cc. flask, and boil for twenty minutes. Titrate the excess of alkali in the hot solution with normal sulphuric acid, using phenolphthalein T.S. as indicator. Make a blank test, using 50 cc. of half-normal sodium hydroxide, and from the comparisons make any necessary corrections. Each cc. of normal sodium hydroxide corresponds to 0.09006 Gm. of $CH_3.CHOH.COOH$.

Preserve in glass-stoppered bottles.

N. F. Preparations—Elixir Calcii Lactophosphatis; Elixir Glycerophosphatum Compositum; Elixir Pepsini Compositum, Elixir Pepsini et Rennini Compositum; Elixir Terpini Hydratis et Creosoti Compositum; Emulsum Olei Morrhuæ cum Calcii Lactophosphate; Syrupus Calcii Lactophosphatis.

Uses—Lactic acid is chiefly used to form the lactates, which are believed to be more easily assimilated than most salts. It is rarely prescribed alone, but may be given in doses of one-half to three fluidrachms (2 to 12 cc.) largely diluted.

Tests for Lactates

Lactates—Solutions of lactates, when acidulated with sulphuric acid, potassium permanganate T.S. added, and the mixture heated, evolve acetaldehyde which is recognizable by its odor.

FEL BOVIS. U. S. Oxgall

Oxgall is the fresh bile of the ox, *Bos taurus* Linné (Fam. *Bovidæ*).

The bile of man and of several animals contains the sodium salts of conjugated cholic acids in varying proportions; in ox and human biles especially glycocholic acid, $C_{26}H_{43}O_6N$; and taurocholic acid, $C_{26}H_{45}O_7NS$. Fresh oxgall is said to contain about 3 per cent, each of sodium glycocholate and sodium taurocholate; also *lecithin*, *cholesterol*, and minor acids and pigments.

Description and Physical Properties—A brownish-green or dark green, somewhat viscid liquid, having a characteristic odor and a disagreeable, bitter taste.

Tests for Identity—Mix two drops of Oxgall with 10 cc. of water and a drop of a freshly prepared solution of 1 part of sucrose in 4 parts of water, and cautiously add sulphuric acid until the precipitate first formed is redissolved. The mixture gradually acquires a brownish-red color, changing successively to carmine, purple, and violet.

A frothy mixture is produced when Oxgall is shaken with water.

Tests for Purity—Specific gravity: 1.015 to 1.025 at 25° C.

Oxgall is neutral or faintly alkaline to litmus paper.

No assay for Oxgall is official, but the following method was suggested by H. B. Dunning, and is used in the standardizing of commercial oxgall preparations:

Assay for Oxgall—Weigh 5 Gm. of Oxgall into a 50 cc. beaker and mix thoroughly with 20 cc. of a warm, saturated solution of magnesium sulphate, adding only a few drops at first, and allow to stand until entirely separated. Pipette off the lower stratum into a small, single-folded filter, resting in a two-ounce funnel. Treat the residue in the beaker, with three additional 20 cc. portions of the saturated solution of magnesium sulphate, warmed as before, and transfer all washings to the same filter. Place the funnel containing the filter and the beaker containing the residue, in a hot-air oven and dry overnight at a temperature not exceeding 110° C. Then add 20 cc. of dehydrated alcohol, or more if required to produce a thin, clear solution, and triturate carefully until the mass is thoroughly disintegrated and all of the bile salts are dissolved. Transfer the solution and undissolved magnesium sulphate to a dried filter and wash both the contents of the beaker and the filter with dehydrated alcohol, into a tared Erlenmeyer flask, until thoroughly extracted. Concentrate the solution on a water bath to about 10 cc. and, when cool, add 80 cc. of ether. Shake thoroughly, allow to stand until the supernatant liquid is clear (about one hour), and separate it. Mix this with 20 cc. of ether and separate as before. Repeat this once more, then place the flask in a warm air oven until most of the ether is driven off and afterwards dry in a hot air oven at 100° C., for two hours.

The residue should weigh at least 2.5 Gm., equivalent to 50 per cent of bile salts.

U. S. P. Preparation—Extractum Fellis Bovis.

Uses—It is administered with the intention of supplying a deficiency of bile in the intestines, in certain indications. A powdered extract is now official, replacing the formerly official purified oxgall. The dose is five to fifteen grains (0.3 to 1 Gm.).

The bile salts in various forms are more generally used than other preparations. They constitute the main active principles of bile, and therefore share the actions and uses of the latter, perhaps with the advantage of more constant composition. When injected into the circulation, they cause severe nervous and cardiac depression, not observed when they are given by the mouth. They are generally credited with a slight antiseptic and laxative action, with enhancing the efficiency of the resinous hydragogue cathartics and with emulsifying and hence favoring the absorption of fat. They stimulate the secretory activity of the liver, increasing both the fluids and solids of the bile.

They have been used in obstructive jaundice, although the rationale is somewhat doubtful; their use in biliary fistula is more reasonable, if the nutrition is noticeably affected.

Unofficial Bile Salts and Bile-Salt Compounds

Bilein, N. N. R.—Sodii Glyco-Taurocholas Bovis-Abbott—A mixture of the essential salts of the bile.
Uses—See preceding article under Oxgall.
Manufactured by The Abbott Laboratories.

Bile Salts-Fairchild, N. N. R.—A preparation obtained from fresh oxgall, consisting essentially of sodium glycocholate and sodium taurocholate, in the proportion existing in ox-bile.
Uses—See preceding article under *Oxgall*.
Dose, from one-half to two grains (0.03 to 0.13 Gm.).
Manufactured by Fairchild Bros. and Foster.

Glycotauro-H. W. & D., N. N. R.—Bile-Salts-H. W. & D.—Concentrated ox-bile freed from bile pigments, standardized to contain 50 per cent of the natural mixture of sodium glycocholate and sodium taurocholate. Each gram represents approximately 15 cc. of fresh ox-bile.

Glycotauro is prepared by evaporating ox-bile in the presence of animal charcoal, extracting the residue with purified methyl alcohol, filtering, evaporating the filtrate and mixing the residue with glycerin.

Glycotauro is a soft semi-solid mass of light brown color, bile-like odor and slightly bitter taste. It is easily soluble in water and alcohol. Its specific gravity is about 1.22.

Uses—See preceding article under *Oxgall*. It is also prepared in tablets with enteric coating.

Manufactured by Hynson, Westcott and Dunning.

Ovogal, N. N. R.—*Albumen Cholicum*—A combination of bile acids with egg albumin.

Ovogal is a greenish-yellow powder, insoluble in water, dilute acids, ether, benzol, fats, etc. Alcohol and acetone do not dissolve it, but after long action remove from it small amounts of the bile acids. Alkalies dissolve ovogal, splitting it into albumin and bile acids (glycocholic and taurocholic acid).

Uses—Ovogal is said to pass the stomach without marked decomposition and to be dissolved and absorbed in the intestine.

For therapeutic indications see preceding article under *Oxgall*.

Dose, from eight to fifteen grains (0.5 to 1 Gm.), several times daily, in capsules, with water, tea, coffee or fruit juices.

Manufactured by J. D. Riedel Aktiengesellschaft, Berlin, Germany (Riedel and Company).

EXTRACTUM CARNIS. N. F. Extract of Beef

[**Ext. Carnis.**—Beef Extract]

The residue obtained from fresh beef broth by evaporation at a low temperature.

Preparation—The solid extract of beef, which is recognized by the N. F., usually known as the "Liebig type", is made by chopping fresh lean beef, cooking it with boiling water, straining, cooling, and separating fat and gelatin from the liquid. Finally this aqueous extract is evaporated to a soft mass in a vacuum apparatus. The yield from beef is from 2 to 3 per cent, one ounce of the extract representing about two pounds of beef. Beef extract of good quality contains the important nitrogenous bases, *creatine*, *creatinine*, *xanthine*, *sarkine*, and *carnine*, and the N. F. provides a test for the amount of nitrogen obtainable. A cheap grade of beef extract is sometimes made by boiling down the liquor or brine in which corned beef has been "pickled". This may be recognized by the high sodium chloride content, sometimes reaching 20 or 25 per cent, and by the presence of saltpetre.

Official Description—A yellowish-brown to dark brown pasty mass.

Odor, Taste, and Reaction—Agreeable meat-like odor and taste; slightly acid.

Solubility—Twenty-five Gm. of Extract of Beef, diluted to 250 cc. with distilled water, yields a nearly clear solution, free from sediment. Separate portions of this solution respond to the following tests:

Tests for Identity and Purity—*Nitrate*—Boil 10 cc. of the solution for one minute with 1.5 Gm. of purified animal charcoal, add distilled water to replace that lost by evaporation and filter: the filtrate produces no blue coloration when one drop is added to three drops of a solution of diphenylamine (1 in 100) in concentrated sulphuric acid.

Distribute 10 cc. of the solution over dry sand or asbestos and dry to constant weight in a flat-bottomed porcelain dish in an oven at a temperature of 105° C.: it yields a residue of not less than 0.75 Gm. equivalent to 75 per cent of solids in the original extract.

Sodium Chloride—Incinerate the residue from 10 cc. of the solution obtained in the preceding test; the ash does not exceed 30 per cent of the residue, nor does the sodium chloride in the ash exceed 10 per cent of the residue when determined as directed under the assay for chlorides (see page 1514).

To 100 cc. of the solution contained in a 500 cc. Kjeldahl flask, add 5 Gm. of barium carbonate and 100 cc. of distilled water and, using a connecting bulb, distil 100 cc. into 10 cc. of half-normal hydrochloric acid T.S. Titrate the excess of acid, using cochineal T.S. as indicator, and from the acid consumed by the distillate calculate the percentage of nitrogen as ammonia. This does not exceed 0.35 per cent of the total solids.

Transfer 25 cc. of the solution to a 100 cc. Erlenmeyer flask, add 50 cc. of alcohol and shake the mixture thoroughly. When the precipitate has subsided, filter, collect the precipitate upon a 9 cm. counterpoised filter, wash the precipitate three times with a mixture of two volumes of alcohol and one volume of distilled water and then dry it to constant weight at 105° C. The weight of this precipitate does not exceed 10 per cent of the total solids. (Reserve the filtrate and washings for the following determination of nitrogen.)

Nitrogen—To an aliquot portion of the alcoholic filtrate from the preceding test, corresponding to 1 Gm. of the alcohol soluble solids, add 4 cc. of sulphuric acid and evaporate to dryness in a 500 cc. Kjeldahl flask. Determine the nitrogen by the Gunning-Kjeldahl method. The amount of nitrogen thus found is not less than 0.06 Gm.

N. F. Preparation—Elixir Carnis et Ferri.

Uses—It is a stimulant, but has little nutritive value. Used in the N. F. Elixir, which was formerly a "wine", and largely as a food and tonic.

CETACEUM. U. S. Spermaceti

[Cetac.]

A fatty substance obtained from the head of the sperm whale, *Physeter macrocephalus* Linné (Fam. *Physeteridæ*).

Preparation—Spermaceti is obtained by the forcible expression of the oleaginous compound found in the head of the sperm whale to separate the liquid portion which is known as sperm oil, and which is a liquid wax. The solid fat is termed *cetin* and also belongs to the class of waxes.

Spermaceti is a mixture of several proximate constituents of which cetin, or cetyl palmitate ($C_{16}H_{33}OCOC_{15}H_{31}$) predominates. When recrystallized from alcohol, *cetin* is obtained, while the alcohol on evaporation deposits an oil, *cetin elain*, which when saponified yields *cetin elaic acid*, an acid resembling but distinct from, oleic acid.

Description and Physical Properties—White, somewhat translucent, slightly unctuous masses, having a crystalline fracture, and a pearly luster. It has a very faint odor and a bland, mild taste. It is free from rancidity.

Spermaceti is insoluble in water, nearly insoluble in cold alcohol, and only slightly soluble in cold petroleum benzin. It is soluble in boiling alcohol, ether, chloroform, carbon disulphide, and in fixed or volatile oils.

Tests for Purity—Specific gravity: 0.938 to 0.944 at 25° C., as determined by the method given under *Cera Flava*, using alcohol warmed to from 38° to 40° C.

Spermaceti melts between 42° and 50° C.

It dissolves completely in fifty parts of boiling alcohol (*paraffin*), and the solution is neutral or not more than slightly acid to moistened litmus paper.

Warm a mixture of about 1 Gm. of Spermaceti and 10 cc. of ammonia T.S. in a stoppered vessel until the Spermaceti is melted, shake it thoroughly for a few minutes, cool and filter; on acidulating this filtrate with hydrochloric acid, it may become turbid, but yields no precipitate (*stearic acid*).

U. S. P. Preparation—Unguentum Aquæ Rosæ.

History—Spermaceti in the time of Shakespeare and previously was called "*parmcety*" and was largely used internally as well as in ointments and cerates. There was considerable mystery as to its real origin for many centuries. It was believed by some to be the sperm, by others to be the marrow and by still others to be the brain substance of the whale. Some believed it to be a solidified form of the froth of foam of the sea.

Uses—Spermaceti is one of the solid fatty substances employed to give consistency to cerates and ointments, as in the well-known ointment of rose water.

Official Products of the Fam. Phasianidæ

OVUM GALLINACEUM. N. F. Fresh Egg

[Ovum Gallin.]

The recently laid egg of the hen, *Gallus domesticus* Temminck (Fam. *Phasianidæ*).

The characteristics by which the freshness of an egg may be determined are the specific gravity which is usually about 1.07 and should not be less than 1.05, the coherence and firmness of the yolk, the absence of wateriness in the white and the character of the chalaza, that invisible membrane which gives coherence to the white.

N. F. Preparation—Linimentum Terebinthinæ Aceticum.

OVI ALBUMEN RECENS. N. F. Fresh Egg Albumen

[Ovi Album.]

The freshly separated liquid white, or albumen, of recently laid egg of the hen, *Gallus domesticus* Temminck (Fam. *Phasianidæ*).

It is composed of about 85 per cent of water, the remainder being solid matter, chiefly a proteid compound with minute amounts of fat, sugar, and inorganic salts. It is precipitated

by most acids (phosphoric and acetic being exceptions) and coagulated by alcohol, heat, tannin, phenol, camphor, etc. It forms precipitates with the salts of most heavy metals and is therefore a valuable antidote in poisoning by mercury, copper and other salts. It is used officially chiefly in preparing the albuminates and peptonate of iron.

N. F. Preparation—Linimentum Opii Compositum.

OVI VITELLUM RECENS. N. F. Fresh Egg Yolk

[Ovi Vitel.]

The freshly separated yolk of recently laid egg of the hen, *Gallus domesticus* Temminck (Fam. *Phasianidæ*).

It is a viscid yellowish liquid and consists of fatty substances, chiefly olein and margarin, which are emulsified by a protein compound called *vitellin*. It also contains inorganic salts, coloring matter, *cholesterol*, and *lecithin*.

N. F. Preparations—Emulsum Olei Morrhuæ Cum Vitello; Glyceritum Vitelli.

Uses—It is used pharmaceutically as an emulsifying agent.

Official Product of the Class Pisces

OLEUM MORRHUÆ. U. S. Cod Liver Oil

[Ol. Morrh.—Oleum Jecoris Aselli]

The fixed oil obtained from the fresh livers of *Gadus morrhua* Linné and of other species of *Gadus*.

Cod Liver Oil may be assayed for its vitamin A potency, and should then contain at least 50 units per Gm. Cod Liver Oil so assayed must be labeled. "This unit is not a measure of the antirachitic activity of Cod Liver Oil."

Preparation—The highest grade of medicinal cod liver oil can be obtained only from strictly fresh cod livers. These should be from healthy fish, and they should be removed from the fish within a few hours after the fish are caught. The oil is separated from the livers by steam cooking. For this purpose, low pressure steam is conducted directly into the cooking kettles containing the livers, and ordinarily it requires only a short time to cook livers sufficiently so that the oil is released from the weakened tissues surrounding the oil cells. The oil is then quickly separated from all water and liver tissue.

When livers of high quality are used and the manufacturing procedure is carried out under carefully controlled, sanitary conditions, the resulting crude oil is of a light yellow color, and of good flavor and odor. Such an oil requires no purification nor chemical refining.

Due, however, to long established trade demands it is necessary to remove the cod liver stearin so that the oil will remain clear at all temperatures above freezing. To accomplish this, the cod liver oil manufacturer chills the crude medicinal oil. After the cod liver stearin has crystallized out, it is a simple matter to separate the stearin and non-freezing oil by filter pressing. In order to preserve the natural vitamin content of cod liver oil, it should be stored out of contact with the air, and preferably in a cool place.

Cod liver oil consists chiefly of olein. Palmitin and stearin are present in small proportions; minute traces of iodine, chlorine, bromine, phosphorus, and sulphur have been reported, but these are not in sufficient quantity to have any medicinal effect. Active constituents of a basic character have also been reported. These were present in oil of a former period as the probable result of putrefactive changes in the livers. Preparations are still upon the market containing these substances and free from any of the oil or oily constituents, but their value has not been demonstrated. An alcoholic extract, *morrhuol*,

made by shaking cod liver oil with alcohol and concentrating the product has also been prepared but is of doubtful value. The most important use for cod liver oil is its favorable influence in rickets and its degree of activity in this respect is capable of demonstration by physiological tests. Dr. Arthur D. Holmes has supplied a summary of the methods now in use (1926), as follows:

Determination of Antirachitic Potency

Different investigators use different procedures for detecting the antirachitic factor. One group of investigators uses a diet consisting of:

Patent flour	95 per cent
Calcium lactate	2.9 per cent
Sodium chloride	2.0 per cent
Iron citrate	0.1 per cent

They rely on the radiographs and microscopic examination of the bones as a basis for judging concerning the presence or absence of rickets in the experimental animals.

Another group of investigators feeds its experimental animals a rickets-producing diet consisting of:

Whole wheat kernel	33 per cent
Whole maize kernel	33 per cent
Gelatin	15 per cent
Wheat gluten	15 per cent
Sodium chloride	1 per cent
Calcium carbonate	3 per cent

These animals are maintained on this diet for a thirty-five-day pre-experimental period. After that, the animals are fed the substance to be tested for five days. Then the animals are killed and the femur and tibia are removed and examined to determine whether calcification has taken place.

Another group of investigators, who believe that the antirachitic factor is also growth-stimulating, feeds its experimental animals a rickets-producing diet consisting of:

Yellow corn	76 per cent
Wheat gluten	20 per cent
Calcium carbonate	3 per cent
Sodium chloride	1 per cent

They supplement their observations concerning the calcium deposition with data concerning increase in the animals' body weight during the experimental period. Other diets have also been proposed.

Professor Dutcher (*Jour. Biolog. Chem.*, vol. LXVI, No. 2, Dec. 1925, p. 401) suggests a colorimetric determination of the phosphorus content of the blood and a chemical determination of the per cent of ash in the bones (the femurs) of the experimental animals, thus avoiding the necessity for exceptional proficiency in pathology required for other proposed tests for determining antirachitic value.

From the above, it is evident that the method for testing for the antirachitic vitamin is not as well standardized as that for testing for the fat-soluble A vitamin, and the entire subject is still in the stage of experimentation.

The vitamin content of cod liver oil is at present its most outstanding assayable factor. It contains at least two vitamins, A and C. See *Vitamins*, page 1168.

While the per cent of fat-soluble A vitamin is not an evidence of the antirachitic value of cod liver oil, it is believed to be a reliable indication of the care with which the cod liver oil has been prepared and preserved. The U. S. P. X has introduced an optional method for determining the vitamin A content and established a definite unit value. On this basis it is known that oils of high vitamin A potency can be produced through care in manufacture and physicians may thus be assured of quality when such products are used. The U. S. P. X vitamin A assay method is as follows:

Vitamin A Assay for Cod Liver Oil—Cod Liver Oil may be assayed by the following process. When so assayed the Oil should contain at least 50 units per Gm. and must be labeled "This unit is not a measure of the antirachitic activity of Cod Liver Oil".

This assay is based upon the estimation of the minimum amount of Cod Liver Oil necessary to meet specific growth-promoting requirements in a standard test animal. The test animals shall be albino rats from a constant source and bred preferably under the control of the experimenter.

The vitamin A potency of Cod Liver Oil shall be expressed in units per gram of oil, the unit to be the minimum daily amount of Cod Liver Oil required to cure induced symptoms of vitamin A starvation in young albino rats, and to cause a gain in weight of from 10 to 20 Gm. within a period of thirty-five days under the conditions of growth and diet specified in this assay.

Place on a vitamin A free diet, rats not less than twenty-five days and not more than twenty-nine days old and weighing not less than 35 Gm., and not more than 45 Gm.

The basal diet is to be composed as follows:

Casein, or desiccated fresh meat, rendered free from vitamin A	18 per cent
Salt mixture, such as that of Osborne and Mendel* or McCollum and Davis†	4 per cent
Starch, sufficient to make	100 per cent

Use sufficient dried brewer's yeast to meet the vitamin B requirements of the animal, mixing it with the basal diet during the vitamin A free period.

The rats shall begin receiving the Cod Liver Oil to be tested after not less than seven days of stationary or declining weight, and from the time of feeding the test oil, they shall be kept in separate cages.

The test period shall continue for thirty-five days and the potency of the oil shall be judged from the rat or rats showing a gain on the thirty-fifth day of between 10 and 20 Gm. over the weight at the beginning of the test, and the cure of the induced symptoms of vitamin A starvation.

Each test shall be controlled by at least two standard rats which have received no Cod Liver Oil. These animals may serve as controls for any number of concurrent tests on which the same basal diet is used.

No oil shall be labeled as assayed by the U. S. P. method unless it contains at least 50 units per Gm. of Oil.

The diet for rats used as breeders shall be composed as follows:

Finely ground whole wheat	66 per cent
Whole milk powder	33 per cent
Sodium chloride	1 per cent

The antirachitic requirements of the breeders shall be assured.

Description and Physical Properties—A pale yellow, thin, oily liquid. It has a peculiar, slightly fishy, but not a rancid odor, and a fishy taste.

Cod Liver Oil is slightly soluble in alcohol, but is soluble in ether, chloroform, carbon disulphide, and in ethyl acetate.

Tests for Identity and Purity—Specific gravity: 0.918 to 0.927 at 25° C.

A solution of 1 drop of the Oil in 1 cc. of chloroform, when shaken with 1 drop of sulphuric acid, acquires a violet-red tint, gradually changing to reddish-brown.

Dissolve 2 Gm. of Cod Liver Oil in 20 cc. of a mixture of equal volumes of alcohol and ether, which previously has been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not more than 1 cc. of tenth-normal sodium hydroxide is required (*free acid*).

Unsaponifiable matter: not more than 1.5 per cent, page 1520.

Saponification value: not less than 180 and not more than 190, page 1519.

Iodine value: not less than 140 and not more than 180, page 1519.

Preserve in a cool place, in well-closed containers which have been thoroughly dried before filling.

Assay—Proceed as directed under the vitamin A assay for *Cod Liver Oil*, page 1188.

U. S. P. Preparation—Emulsum Olei Morrhuæ.

N. F. Preparations—Emulsum Olei Morrhuæ cum Hypophosphitibus; Emulsum Olei Morrhuæ cum Malto; Emulsum Olei Morrhuæ cum Vitello.

Uses—Cod liver oil is used as a nutrient and alterative in wasting diseases, notably phthisis. Dose, one to four fluidrachms (4 to 15 cc.).

RENNINUM. N. F. Rennin

The partially purified milk-curdling enzyme obtained from the glandular layer of the stomach of the calf, *Bos taurus* Linné (Fam. *Bovidæ*), and capable of coagulating not less than 25,000 times its weight of fresh milk. Rennin of a higher coagulating power may be brought to the standard by admixture with sodium chloride and lactose. Rennin deteriorates rapidly and must be kept in well-stoppered, amber-colored bottles, and stored in a cool place.

Preparation—It is usually prepared by digesting the mucous membrane of calves' stomachs for twenty-four hours in a one-half per cent sodium chloride solution, filtering, then adding hydrochloric acid to the filtrate to make one per cent acid, again filtering and saturating the filtrate with sodium chloride. On standing, the enzyme separates as a white flocculent mass and is carefully dried.

Official Description—Rennin occurs as a grayish-white or yellowish-white powder, or as pale yellow grains or scales. It is slightly hygroscopic.

Odor and Taste—Characteristic and slightly saline taste and a peculiar, not unpleasant odor.

Solubility—It is slowly soluble in water and in diluted alcohol, the solutions being more or less opalescent.

Tests for Purity—When mounted in water or diluted alcohol and examined microscopically it shows no cellular structure, and no blue coloration is produced on the addition of iodine T.S.

*See Jour. Biol. Chem., Vol. 15, page 317 (1913).
†See Jour. Biol. Chem., Vol. 33, page 55 (1918, No. 185).

Assay—Mix 0.1 Gm. of Rennin with 50 cc. of distilled water by gentle stirring or trituration in a mortar (vigorous shaking or violent agitation must be avoided) and allow the liquid to stand for exactly 15 minutes. Place 50 cc. of cow's milk having an acidity of not less than 0.14 per cent nor more than 0.15 per cent calculated as lactic acid (increasing the acidity of the milk, if low, by the addition of the required amount of lactic acid, or reducing it, if high, by the addition of the required quantity of sodium hydroxide) in a beaker about 12 centimeters high and 5 centimeters in diameter. Warm the milk rapidly on a water bath to 43° C., add 1 cc. of the Rennin solution and stir the mixture slowly for 10 seconds. Maintain the temperature at 43° C., until the milk begins to thicken, as shown by a distinctly convex surface when the beaker is tipped to an angle of about 45°. This thickening must take place within 10 minutes from the time of the addition of the Rennin solution. An additional 30 seconds on the water bath produces a firm curd.

The acidity of the milk used is ascertained by titrating 50 cc. of the undiluted milk with normal solution of sodium hydroxide, using phenolphthalein T.S. as indicator.

N. F. Preparation—Elixir Pepsini et Rennini Compositum.

Uses—It is used to produce a curd in milk, oftentimes for a food called *junket*, also as a digestant. The form in which it is usually sold is called "Essence of pepsin" (see page 332), or as *junket tablets* or a preparation called *liquid rennet*.

Official Products of the Class Insecta

CANTHARIS. U. S. Cantharides

[**Canthar.**—Spanish Flies, Russian Flies]

Cantharides consists of the dried insects, *Cantharis vesicatoria* (Linné) De Geer (Fam. *Meloideæ*).

Cantharides yields not less than 0.6 per cent of cantharidin and not more than 10 per cent of moisture.

Cantharides owe their blistering properties to *cantharidin* $C_{10}H_{12}O_4$, which is the inner anhydride (lactone) of cantharidic acid.

Cantharidin occurs as colorless glistening, inodorous crystals; 0.1 Gm. on incineration should leave no weighable residue. Cantharidin is very slightly soluble in water, petroleum benzin or alcohol (90 per cent); soluble in chloroform (1 in 65), in acetic ether (1 in 150), and in acetone (1 in 40), and is soluble also in fixed oils. A 0.1 per cent solution in a fixed oil raises blisters when kept in contact with the skin. The melting point is from 210° and 212° C. Cantharidin slowly volatilizes at 100° C., more rapidly at higher temperatures. It is soluble in solution of sodium hydroxide, the solution depositing crystals of cantharidin when acidified. Gently warmed with sulphuric acid it yields a colorless solution, from which it is separated unchanged when freely diluted with water.

Cantharidin may be obtained from various species of *Cantharis* or of *Mylabris*. It may be prepared by digesting powdered cantharides with a mixture of concentrated sulphuric acid and acetic ether at ordinary temperature, then mixing with barium carbonate and exhausting the mixture with acetic ether. The solvent may be removed by distillation and the residue then allowed to stand for some time to allow the cantharidin to crystallize. The resulting crystals may be washed with petroleum benzin to remove the fat and then recrystallized from hot alcohol.

Uses—Preparations of cantharidin are used in place of corresponding preparations of cantharides and have the advantage of being more cleanly and more uniform in strength. Cantharidin is recognized by the British, French, and Swiss Pharmacopœias. Cantharidin is more toxic to the kidney when the urine is acid than when it is alkaline.

Dose—$\frac{1}{250}$ to $\frac{1}{120}$ grain (0.00025 to 0.0005 Gm.).

An assay has been appended to the U. S. P. X text of cantharides to indicate the cantharidin content. In the British Pharmacopœia, cantharidin, obtained from any of the species of Cantharis or Mylabris, has replaced the drug, and all British preparations are made directly from cantharidin, but it is so costly and difficult to obtain that its replacement of cantharides in the United States Pharmacopœia was not believed to be practicable.

Description and Physical Properties—*Unground Cantharides*—From 15 to 25 mm. in length, 5 to 8 mm. in breadth, oblong, somewhat compressed above; of a brilliant green or bluish-green, metallic luster, changing in different parts, especially beneath to a golden-green; head triangular, separated into two lateral lobes by a faint median line; mandibles stout and partly concealed; antennæ filiform, of eleven conical joints, the upper ones being black; eyes comparatively small; prothorax angulate; legs with five tarsal joints; wings membranous and brownish; elytra or wing sheaths each with two parallel lines and finely wrinkled; odor strong, disagreeable; taste slight, afterwards acrid.

Cantharides with an ammoniacal odor must not be used.

Powdered Cantharides—Grayish-brown, with shining green particles and a number of long, pointed, spicules 0.500 mm. in length and 0.020 mm. in width.

Assay—Place 15 Gm. of Cantharides, in moderately coarse powder in a stout bottle of not less than 250 cc. capacity, add 150 cc. of a mixture of benzene, two volumes, and purified petroleum benzin, one volume, and then add 2 cc. of hydrochloric acid. Stopper the bottle tightly, shake it

well, and allow it to stand about ten hours. Now gradually warm the bottle and its contents to about 40° C., and maintain it at approximately that temperature with frequent shaking during three hours, avoiding evaporation. If necessary add additional solvent to replace any lost by evaporation. Cool the mixture, decant or filter off 100 cc. of the clear solution, and evaporate this rapidly in a tared beaker or wide-necked flask to a volume of about 5 cc. Add 5 cc. of chloroform to the residue and set it aside in a moderately warm place. When the solvent has all evaporated, add to the crystals 10 cc. of a mixture of equal volumes of dehydrated alcohol and purified petroleum benzin, which has previously been saturated with pure cantharidin, allow the mixture to stand during fifteen minutes, and then decant the liquid, through a pledget of purified cotton. Wash the crystals with successive portions of a saturated solution of cantharidin, similar to that directed above, until free from fat, and coloring matter, and pass the washings through the same pledget of purified cotton. Then wash the cotton with a very small quantity of warm chloroform to dissolve any adhering crystals, collect the chloroform in the tared flask or beaker containing the washed crystals, evaporate the solvent with the aid of a blast of air, dry the crystals at 60° C. for one half hour, and weigh. The resulting weight will be the amount of cantharidin obtained from 10 Gm. of Cantharides.

U. S. P. Preparations—Ceratum Cantharidis; Emplastrum Cantharidis (from Cerate); Tinctura Cantharidis.

Uses—Cantharides are used as an aphrodisiac and are poisonous. When applied externally they produce vesication. Dose, one-half grain (0.03 Gm.).

COCCUS—Cochineal

See chapter on Coloring Principles, page 842.

CERA FLAVA. U. S. Yellow Wax

[Cer. Flav.—Beeswax]

Yellow Wax is obtained by melting and purifying the honeycomb of the bee, *Apis mellifera* Linné (Fam. *Apidæ*).

Preparation—Wax is now known to be a peculiar secretion of bees. Yellow wax is obtained on the large scale by first abstracting the honey from the combs by shaving off the ends of the cells, draining, and then placing them in centrifugals. The honey is rapidly whirled out, water is added, and the wax is thoroughly and quickly cleaned; it is then melted and strained and run into flat dishes or molds to cool and harden.

Beeswax is a mixture of three different substances, which may be separated from one another by alcohol—*viz.*: 1. *myricin*, insoluble in boiling alcohol, and consisting chiefly of *myricyl palmitate*, $C_{30}H_{61}(C_{16}H_{31}O_2)$, which is an ester of *palmitic acid* $C_{16}H_{32}O_2$, and *myricyl alcohol*, $C_{30}H_{62}O$; 2. *cerin* or *cerotic acid*, $C_{27}H_{54}O_2$ (formerly called *cerin* when obtained only in an impure state), which is dissolved by boiling alcohol, but crystallizes out on cooling; 3. *cerolein*, which remains dissolved in the cold alcoholic liquid. This latter is probably a mixture of fatty acids, as indicated by its acid reaction to litmus paper.

Description and Physical Properties—A solid, varying in color from yellow to grayish-brown. It has an agreeable, honey-like odor, and a faint, characteristic taste.

When cold, it is somewhat brittle, and when broken presents a dull, granular, non-crystalline fracture. It becomes plastic from the heat of the hand.

Yellow Wax is insoluble in water and sparingly soluble in cold alcohol. Boiling alcohol dissolves the cerotic acid and a portion of the myricin, which are constituents of Yellow Wax. It is completely soluble in chloroform, ether, and in fixed or volatile oils, partly soluble in cold benzene or in carbon disulphide, and completely soluble in these liquids at about 30° C.

Tests for Identity—Specific gravity: 0.950 to 0.960 at 25° C. determined as follows: Melt the Wax at a low temperature and allow it to fall in separated drops from just above the surface into alcohol that has been warmed to from 45° to 50° C. Allow the globules to remain in the alcohol until it has cooled spontaneously to room temperature (20° to 25° C.), then remove the Wax and keep it at room temperature for twenty-four hours. Prepare a mixture of four volumes of alcohol and enough distilled water to make ten volumes and allow it to stand until free from air bubbles. Moisten the globules of Wax with distilled water by means of a brush, and place them by means of forceps in the alcohol solution just prepared and contained in a beaker. Then add alcohol, or air-free distilled water, as required to the mixture, kept at 25° C., until the globules of the Wax

float and rest indifferently in the liquid. Finally determine the specific gravity of the alcohol-water mixture. The figure thus obtained represents the specific gravity of the Wax examined.

Yellow Wax melts between 62° and 65° C.

Tests for Purity—Boil 1 Gm. of Yellow Wax for half an hour with 35 cc. of an aqueous solution of sodium hydroxide (1 in 7), the volume being preserved by the occasional addition of distilled water; on cooling, the Wax separates without rendering the liquid opaque, and no precipitate is produced in the liquid after filtration through glass wool or asbestos on the addition of an excess of hydrochloric acid (*fats or fatty acids, Japan wax, rosin or soap*).

Warm about 3 Gm. of Yellow Wax, accurately weighed, in a 200 cc. flask with 25 cc. of neutral dehydrated alcohol until melted, add 1 cc. of phenolphthalein T.S. and while warm titrate with half-normal alcoholic potassium hydroxide until a permanent, faint pink color is produced: the acid number so obtained is not less than 18 and not more than 24, page 1512. Now add 25 cc. of half-normal alcoholic potassium hydroxide and 50 cc. of alcohol, boil the mixture for four hours under a reflux condenser, and titrate the excess of the alkali with half-normal hydrochloric acid: the ester number so obtained is not less than 72 and not more than 77, page 1517.

U. S. P. Preparations—Ceratum Cantharidis; Ceratum Resinæ; Unguentum; Unguentum Acidi Borici; Unguentum Acidi Tannici (from Unguentum); Unguentum Belladonnæ; Unguentum Phenolis; Unguentum Picis Pini.

N. F. Preparations—Ceratum Resinæ Compositum; Emplastrum Fuscum Camphoratum; Mulla Creosoti Salicylata; Unguentum Picis Compositum; Unguentum Resorcinolis Compositum.

Uses—Its use is chiefly to give consistence to fatty vehicles.

CERA ALBA. U.S. White Wax

[**Cer. Alb.**—Bleached Beeswax]

Yellow Wax, bleached.

Preparation—The color of yellow wax is discharged by exposing it with an extended surface to the combined influence of air, light, and moisture. The process of bleaching is often conducted upon a large scale. The wax, previously melted, is made to fall in streams upon a revolving cylinder kept constantly wet, upon which it concretes, forming thin layers. These, layers are spread upon linen cloths stretched on frames and exposed to the air and light, care being taken to wet and occasionally turn them. In a few days they are partially bleached; but to deprive the wax completely of color it is necessary to repeat the whole process once, if not oftener. When sufficiently white, it is melted and cast into small circular cakes.

Description and Physical Properties—A yellowish-white solid, somewhat translucent in thin layers. It has a faint, characteristic odor, is free from rancidity, and is nearly tasteless.

Tests for Identity and Purity—The acid value is not less than 17 and not more than 23, and the ester value not less than 72 and not more than 79, as determined by the methods under *Cera Flava*.

In other respects White Wax has the characteristics of, and responds to, the tests for identity and purity under *Cera Flava*.

U. S. P. Preparations—Ceratum; Unguentum Aquæ Rosæ.

N. F. Preparations—Ceratum Camphoræ; Ceratum Plumbi Subacetatis; Petroxolinum Spissum; Unguentum Camphoræ; Unguentum Sinapis.

Uses—Wax is used in pharmacy principally to give consistence to cerates and ointments.

ACIDUM FORMICUM. N.F. Formic Acid

An aqueous solution containing not less than 24 per cent and not more than 26 per cent of HCOOH.

Preparation—It occurs free in ants, especially *Formica rufa*, from which its name is derived, also in other insects and the secretion of some animals. It is also prepared by oxidizing methyl alcohol, by the direct combination of CO and KOH at 100° C. and by other chemical processes. Commercially it is prepared by heating together 50 parts of glycerin and 50 parts of oxalic acid to 105° C., cooling to 50° C., again adding 50 parts of oxalic acid and then distilling at 115° C.

Formic Acid is a clear, colorless liquid; of a strongly acid reaction and a characteristic pungent odor. Specific gravity about 1.058 at 25° C. It is miscible with water or alcohol. (For further tests and the assay see the N. F. V.)

N. F. Preparation—Spiritus Acidi Formici.

Uses—Used chiefly to produce the alkaline formates for making syrups and elixirs, but it has been used as an irritant and vesicant when applied locally—and as a stimulant, like ammonia, in a dose of five minims (0.3 cc.).

Organs of Animals

The following statement concerning the therapeutic value of the animal glands, commonly spoken of as *endocrins*, has been copied in abstract, from the 1925 N. N. R., with permission.

"The discovery of the importance of internal secretions has led to extensive clinical trials with preparations of the so-called ductless glands, and other tissues which elaborate or are supposed to elaborate, such internal secretions. Four of these, the thyroid and suprarenal glands, the posterior lobe of the pituitary, and insulin obtained from the pancreas, have given decisive therapeutic results. Two of these are official in the Pharmacopœia". The active principle of the suprarenal, now official as *epinephrine* and that of the pituitary as *solution of pituitary*, have won a recognized place in therapeutics. "The other organ products are scarcely beyond the experimental stage. Their active principles have not been isolated, and they are most commonly used in the form of the powdered dried gland. The gross fat and connective tissue is removed as completely as possible, and the drying is conducted at a relatively low temperature. The powder (often improperly called an 'extract') is frequently compressed into tablets". The strength of these is usually stated in terms of the dried gland. "Since in general, there are no tests for the quality, or even identity of these powdered products, the physician, unless he can himself supervise their preparation, is forced to rely on the general reputation of the manufacturer."

PITUITARIUM. U. S. Pituitary

[**Pituitar.**—Hypophysis Sicca U. S. P. IX]

Pituitary is the cleaned, dried and powdered posterior lobe obtained from the pituitary body of domesticated animals which are used for food by man.

Description and Physical Properties—A yellowish or grayish amorphous powder, having a characteristic odor. It is only partially soluble in water.

U. S. P. Preparation—Liquor Pituitarii.

The pituitary gland is a small, reddish, ellipsoidal organ situated in a depression of the sphenoid bone and attached to the brain by a pedicle. It consists of two lobes, an anterior portion, which is the larger, and a posterior portion, the part of the gland which is official. Both lobes possess therapeutic activity, but are different in their action. The anterior portion is essential for life, death soon following its removal, and if partially destroyed or if diseased, normal growth is retarded or other evidences of malnutrition follow. The anterior lobe is not largely used in medical practice.

Uses—The posterior lobe, containing an active principle which has been called *pituitrin*, has a marked effect upon plain muscle, especially upon those of the blood vessels and the uterus. Extract of the posterior lobe injected subcutaneously is employed against uterine atony and in postpartum as well as in other forms of uterine hemorrhage. Pituitary extracts should not be injected

during the first stage of labor because, if the cervix be not fully dilated, the energetic contractions may cause rupture of the uterus. It has also been recommended in shock and in various other conditions of temporary low blood pressure, but the benefits are doubtful. It is useful in intestinal paresis whether following abdominal operations or complicating pneumonia. It has also been used to control diabetes insipidus with temporary benefit. Oral administration gives feeble or doubtful results; and the extracts should always be injected hypodermically or intramuscularly. The dose of the dried gland is one-half grain (0.03 Gm.).

LIQUOR PITUITARII. U. S. Solution of Pituitary

[**Liq. Pituitar.**—Liquor Hypophysis U. S. P. IX, Pituitary Extract]

Solution of Pituitary contains the water-soluble principle or principles from the fresh posterior lobe of the pituitary body of cattle, 1 cc. having an activity upon the isolated uterus of the virgin guinea pig, corresponding to not less than 80 per cent and not more than 120 per cent of that produced by 0.005 Gm. of the Standard Powdered Pituitary, prepared as directed below. The solution should be sterile.

Preparation—Commercially pituitary solutions are prepared in much the same manner as described in detail for the preparation of the standard powder (see below).

Description and Physical Properties—A transparent liquid, colorless, or nearly so, having a faint, characteristic odor.

Assay—Prepare a solution as follows: Carefully weigh a suitable amount of the dried Standard Powdered Pituitary, place this weighed powder in a small agate mortar and moisten with a few drops of distilled water containing 0.25 per cent of acetic acid. Triturate the moistened powder thoroughly until the whole is of an impalpable frothy consistence. Add a few cc. of the 0.25 per cent acetic acid solution and stir the mixture thoroughly. Transfer to a hard glass test tube or beaker; rinse the small agate mortar with the acetic acid solution and add the rinsings to the pituitary mixture; then add enough 0.25 per cent acetic acid to make the final volume of the mixture of the same number of cc. as the number of milligrams of dried pituitary powder originally taken. Heat this mixture to the boiling point for not more than one minute and filter. The filtrate contains in each cc. the active principle of 0.001 Gm. of the dried standard powder. Place this solution in hard glass ampuls and sterilize by fractional sterilization for twenty minutes on three successive days at a temperature not exceeding 100° C. Preserve in a cool place (from 5° to 20° C.). This standard solution should not be kept more than six months.

The apparatus used for making the test may be any modification of the general type for studying the activity of the isolated smooth muscle of mammals. It must be provided with an accurate temperature-regulating device. The chamber in which the uterus is suspended should have a capacity of not less than 100 cc.

Use healthy guinea pigs weighing between 175 Gm. and 350 Gm. They should not have been pregnant and should not be in heat. It is recommended that young female pigs be segregated at the time of weaning and kept thereafter out of sight and smell of the males.

Kill a guinea pig by a blow on the head, or by decapitation, and immediately remove the entire uterus from the body. Suspend a part or all of one horn of the uterus in a chamber containing oxygenated Locke-Ringer solution (page 1547), one end of theuterus being attached to a muscle lever which is weighted as necessary. The temperature of the bath should be between 37° and 38° C. but should not vary more than one-tenth of a degree throughout the whole assay. When the uterus is completely relaxed, which is generally in from fifteen to thirty minutes, it is ready to begin the test. This is done by adding alternately varying doses of the standard extract and of the solution to be tested to the bath in the muscle chamber until quantities of the two solutions are found which give equal, sub-maximal contractions in at least two successive pairs of contractions. The strengths of the two solutions are in inverse ratio to the quantities necessary to produce these equal contractions.

Standard Powdered Pituitary

Select a number, not less than 25, of fresh posterior lobes of the pituitary body of cattle, removed within thirty minutes of the death of the animal, and carefully free them from all extraneous tissue, immediately after their removal. As soon as they are so prepared, drop them into a flask containing a quantity of acetone corresponding to not less than 4 cc. of acetone for each pituitary body. Allow them to remain in the acetone for three hours and then remove them and immediately cut them into small pieces with scissors and place the material in fresh acetone equal to that first employed. Macerate overnight and then remove it and dry it in a vacuum desiccator

over calcium chloride, at a temperature not above 50° C. for five hours. At the end of this time remove the material and grind it in a mortar until it will pass through a No. 40 sieve. Dry this powder for at least twelve hours in a vacuum desiccator over calcium chloride at a temperature not over 50° C. Extract this dried powder in a small Soxhlet continuous extraction apparatus with acetone for three hours and again dry it in a desiccator over calcium chloride for twelve hours. This dried powder should be preserved in a cool, dark place, in sealed ampuls *in vacuo*, or in vacuum desiccators over calcium chloride until used for the preparation of the standard solution.

Leave the material in the acetone.

Uses—The solution of pituitary body is the form most frequently used, as it possesses the advantage over the dried glands of more definite standardization therefore greater dependability. The assay is complicated and requires delicate mechanism and, as the best method is yet to be proven, the U. S. P. has authorized the United States Hygienic Laboratory at Washington, D. C., to prescribe the exact details of the test. Its uses are the same as described under *Pituitarium* (see page 1193), the dose being fifteen minims (1 cc.). Solution of Pituitary is offered the profession under various trade names such as *Pituitary Liquid, Pituitary Solution, Solution Pituitary Extract, Pituglandol, Pituitrin, Hypophysin, Pituitol*, etc.

Pituitrin "S" (*Surgical*) is a stronger preparation than that of the U. S. P.

Unofficial Pituitary Preparations

Desiccated Pituitary Body-Armour, N. N. R.—The dried substance of the entire pituitary body of the ox, including the infundibulum and the anterior and posterior lobes without the addition of preservative or diluent. It is said to contain all the active principles naturally existing in the gland.

Pituitary body desiccated-Armour is a light yellowish-gray powder, practically odorless and tasteless. One part represents approximately 5 parts of fresh gland.

Uses—See Pituitary Gland. Dose, from one to three grains (0.06 to 0.2 Gm.), three times a day.

Manufactured by Armour and Company.

Desiccated Pituitary Substance (Anterior Lobe) Armour, N. N. R.—The anterior lobe from the pituitary of the ox, separated, dried and powdered without the addition of preservative or diluent.

Uses—Hyperactivity of the anterior lobe has been believed to produce accelerated and abnormal growth (gigantism). Preparations of the anterior lobe have been given in the later stages of acromegaly, with reported benefit in some instances, but there is doubt as to its value in this condition. It is contraindicated in the early stages of acromegaly. Dose, from one to ten grains (0.06 to 0.60 Gm.) in powder or tablet.

Manufactured by Armour and Company.

EPINEPHRINA. U. S. Epinephrine

[**Epineph.**—Lævo-Methylaminoethanolcatechol]

Epinephrine is [$C_9H_{13}O_3N$ or $C_6H_3(OH)_2(CHOH.CH_2NHCH_2)$.—1,2-dihydroxy-4²-methyl-amino ethyl-4¹-ol benzene] a substance with feeble basic properties, obtained from the suprarenal gland of the sheep or other animal; also made synthetically. In solution it is generally dispensed in the form of a salt such as epinephrine borate, chloride or sulphite.

Preparation—This active constituent, of the suprarenal glands, *epinephrine*, is alkaloidal in character and was discovered by Dr. John J. Abel. Fuerth also claimed the discovery of an active constituent which he called *suprarenine* (*suprarenaline*), and Takamine introduced a crystalline substance which he named *adrenalin*. These substances proved to be identical, and the official title is that originally given to it by Abel.

Adrenalin is prepared by digesting the finely cut glands with acidulated water for five hours, at about 70° C, then heating to 90° C. to coagulate albuminoids, and expressing the mixture. The digestion in acidulated water is repeated, the expressed liquids freed from fat, concentrated *in vacuo*, mixed with alcohol to precipitate inert constituents, and then precipitated by the addition of ammonia water. The crude adrenalin which separates, after several hours' standing, is purified by solution in acid alcohol and again precipitated by the addition of ammonia water. It is also prepared synthetically.

Description and Physical Properties—A white or light brownish, microcrystalline, odorless powder, gradually darkening on exposure to the air.

Epinephrine is very slightly soluble in water and in alcohol. It is insoluble in ether, chloroform, acetone, and in fixed or volatile oils.

Tests for Identity and Purity—Epinephrine combines with acids, forming salts which are readily soluble in water, and from these solutions the base, may be precipitated by ammonia or alkali carbonates.

The acid solution is not affected by solutions of trinitrophenol, tannic acid, phosphomolybdic acid, mercuric potassium iodide, or platinic chloride.

A saturated aqueous solution of Epinephrine is slightly alkaline to litmus paper.

A slightly acid, aqueous solution of Epinephrine (1 in 1000) gives with ferric chloride T.S. an emerald-green color, turning to cherry-red and finally to brown on standing. Other oxidizing agents produce red, pink, or violet colors which change to brown. Fixed alkali hydroxides cause the solution to darken on standing, but do not precipitate the Epinephrine.

The ash from 0.1 Gm. is negligible.

Preserve in well-closed containers, protected from light.

Uses—Epinephrine acts peripherally on a variety of structures, probably by stimulating the sympathetic nerve endings. Its most important therapeutic actions consist of a constriction of the blood vessels, with consequent high rise of blood pressure; a stimulation of the vagus center with slowing of the heart, and a direct stimulant and tonic effect on the heart muscle, similar to that of digitalis. Large doses also cause glycosuria. The effect of a single dose is fleeting. It is not irritant. The effects are seen on local application and intravenous and intramuscular injection. When given to animals, by mouth or hypodermically, moderate doses have almost no action.

Dilute watery solutions rapidly lose their strength, the deterioration being accompanied by a reddish or brownish discoloration.

The incompatibilities of epinephrine are the same as those of alkaloids. Its solutions should be kept tightly-stoppered and protected from the light.

Epinephrine is chiefly used locally for its vasoconstrictor action, in hemorrhage and in catarrhal and congestive conditions. It cuts short asthmatic paroxysms (when used as a spray for the larynx and for hypodermic injections). Intravenous injections are effective in shock and anesthesia accidents (care being taken not to give an overdose). It has also been recommended in heart disease but opinions are divided as to the benefits to be expected from administration by mouth.

The vasoconstrictor action of epinephrine is used to intensify and prolong the anesthetic effect of local anesthetics by retarding the circulation in the affected part and thus hindering the dilution of the anesthetic agent by too rapid absorption into the blood stream.

Dose—From 5 to 30 minims (0.3 to 2.0 cc.) of a 1 in 1000 solution, every two or three hours. Hypodermically, from 1 to 15 minims (0.006 to 1 cc.) of a 1 in 1000 solution, diluted with sterile water. Locally, it is used in solution varying in strength from 1 in 15,000 to 1 in 1000, for ordinary applications, in oily solution for sprays, in ointment for application to mucous membranes, such as the eye or the nose, where a slower but more lasting action is desired, and in suppositories.

The identical product is sold under various names such as *adrenalin, adnephrin, adrenamine, epirenan, hemisine, hemostatin, paranephrin, renaline, renalina, supracapsulin, supranephrane,* and *suprarenalin.*

LIQUOR EPINEPHRINÆ HYDROCHLORIDI. U.S. Solution of Epinephrine Hydrochloride

[Liq. Epineph. Hydrochlor.]

Solution of Epinephrine Hydrochloride is a solution of epinephrine in water and hydrochloric acid, containing in each 100 cc. not less than 0.095 Gm. and not more than 0.105 Gm. of $C_9H_{13}O_3N$.

Solutions of the isolated active principle of the suprarenal glands have largely replaced, in practice, solutions prepared from the dried suprarenal gland. They have a number of advantages over the latter; they may be made of definite strength, whereas the activity of commercial preparations of the dried glands varies greatly, and they are less liable to bacterial infection. They are, however, much more expensive than solutions made from the dried gland.

Epinephrine is exceedingly sensitive to oxidizing agents. It is decomposed by the slightest trace of iron or other metals in the water and special purity tests of the water are necessary for making a permanent solution. Then the water must be recently boiled and cooled to free it from air. The solution must be slightly acid and must contain a preservative to prevent the growth of germs and fungi, to which this solution is prone. And finally it needs to be bottled with the exclusion of air and should contain a reducing agent to prevent oxidation.

Prof. Wilbur L. Scoville suggests the following formula:

Epinephrine	1.0 Gm.
Trichlor-tertiary butyl alcohol	5.0 Gm.
Sodium chloride	8.5 Gm.
Diluted hydrochloric acid	3.0 cc.
Sodium bisulphite	2.0 Gm.
Sterilized distilled water to make	1000 cc.

Trichlor-tertiary butyl alcohol has been found by test to be the most efficient antiseptic for this preparation. Other antiseptics in use in this solution are *chloroform* or *chloral hydrate*, used by some, and *camphor* the least efficient of all. Finally, if the solution is to be stored it should be bottled in bottles from which the air has been removed and replaced with some non-oxidizing gas.

Description and Physical Properties—A nearly colorless, slightly acid liquid, gradually turning dark on exposure to air and light. When the solution has become brown in color or contains a precipitate it must be rejected.

Tests for Identity—The addition of 1 drop of ferric chloride T.S. to 10 cc. of the solution produces an emerald-green color which soon turns to a cherry-red and finally to brown. Other oxidizing agents produce red to pink or violet colors which change on standing. Fixed alkali hydroxides darken it, but do not precipitate the epinephrine.

Uses—For uses and dose see Epinephrina (page 1196).

Unofficial Suprarenal or Related Products

SUPRARENALUM SICCUM—Dried Suprarenals
(U. S. P. IX)

[Desiccated Suprarenal Glands]

The suprarenal glands of animals which are used for food by man. The glands must be cleaned, dried, freed from fat, and powdered, and contain not less than 0.4 per cent and not more than 0.6 per cent of epinephrine, the active principle of the suprarenal gland. One part of Dried Suprarenals represents approximately 6 parts of fresh glands, free from fat. Assayed biologically 1 Gm. of Dried Suprarenals contains the equivalent of ten milligrammes of lævo-methylaminoethanol-catechol.

A light yellowish-brown, amorphous powder; slightly characteristic; partially soluble in water.

Dried Suprarenals contain not more than 7 per cent of moisture, and the yield of ash does not exceed 7 per cent.

Assay—Add 0.005 Gm. of finely powdered manganese dioxide and 10 cc. of distilled water to 0.01 Gm. of Dried Suprarenals; thoroughly shake the mixture several times during one hour and filter. Compare the color of the filtrate in a test tube or in any convenient manner, with the color of cobaltous chloride T.S. and dilute gold chloride T.S. combined as follows: Mix 1.85 cc. of cobaltous chloride T.S. with 0.95 cc. of diluted gold chloride T.S. and 7.2 cc. of distilled water; the color corresponds to 0.2 per cent of epinephrine in the filtrate obtained above; 2.95 cc. of cobaltous chloride T.S. with 1.25 cc. of diluted gold chloride T.S. and 5.8 cc. of distilled water corresponds in color to 0.4 per cent of epinephrine; 4.05 cc. of cobaltous chloride T.S. with 1.35 cc. of diluted gold chloride T.S. and 4.6 cc. of distilled water corresponds in color to 0.6 per cent of epinephrine; 5.15 cc. of cobaltous chloride T.S. with 1.55 cc. of diluted gold chloride T.S. and 3.3 cc. of distilled water corresponds in color to 0.8 per cent of epinephrine.

The percentages of epinephrine indicated by the above color standards are based upon the maceration of 0.01 Gm. of the Dried Suprarenals in 10 cc. of distilled water as directed above, and filtering. In samples containing more than 0.8 per cent of epinephrine, 0.005 Gm. of the Dried Suprarenals may be taken—in

which case the percentage stated above—as indicated by the color standards, should be doubled. The standard color solutions keep unchanged if sealed in glass tubes.

For a method of assaying Dried Suprarenals, see Biological Assays.

Uses—Desiccated suprarenal glands in powder is used in Addison's disease, and solutions have been employed as hemostatics. Dose, of the dried glands, four grains (0.25 Gm.).

L-Suprarenin Synthetic Bitartrate, N. N. R.—The acid tartrate of synthetic epinephrine obtained by the method of Stolz and Flaecher (*Ztschr. f. physiol. Chem.* 58:189).

Synthetic epinephrine (the free base) is a white odorless powder nearly insoluble in water, alcohol and ether. It melts at from 211° to 212° C. It rotates polarized light to the left, the rotation being

$$[a]\frac{19.6°}{D} = -51.4°$$

It has the chemical and physical properties of epinephrine obtained from suprarenal glands.

L-Suprarenin Synthetic Bitartrate is a white, odorless powder soluble in water and yielding a solution which has an acid reaction. L-suprarenin synthetic bitartrate melts at 149° C. and its aqueous solution rotates polarized light to the left.

Uses—See Epinephrine. Synthetic epinephrine has the physiologic effects of natural epinephrine obtained from suprarenal glands.

Manufactured by H. A. Metz Laboratories, Inc.

Tyramine Hydrochloride, N. N. R.—Tyramine—Parahydroxyphenylethylamine hydrochloride—$OH.C_6H_4CH_2CH_2NH_2.HCl$.—The hydrochloride of the base parahydroxyphenylethylamine $OH.C_6H_4.CH_2.CH_2.NH_2$ obtained synthetically.

Uses—The actions of tyramine hydrochloride resemble those of epinephrine; they are less powerful but more persistent. It is absorbed much more readily.

Tyramine hydrochloride produces a rise of blood pressure, mainly by vasoconstriction. This suggested its employment in shock or collapse, but it has not been very successful. It is useless as a local hemostatic.

Tyramine hydrochloride seems to have a possible field in obstetrics, since it contracts the uterus and thus checks post-partum hemorrhage; but it is not so powerful as pituitary extract. It is also useful in that it antagonizes the respiratory depression of morphine, thus rendering this drug safer in childbirth. Dose, tyramine hydrochloride acts fairly well from the stomach, but is best given hypodermically, in doses of from one-third to two-thirds grain (0.02 to 0.04 Gm.), dissolved in water.

The base parahydroxyphenylethylamine was isolated from ergot by Barger and also prepared synthetically by him by the reduction of parahydroxyacetonitrile with sodium in alcoholic solution. (Transactions of the Chemical Society, 1909, xcv.) It had previously been obtained by heating tryosine; hence its name. It is chemically and physiologically related to epinephrine.

Tyramine hydrochloride occurs as a white, or almost white, crystalline powder, soluble in water and forming a neutral solution.

Manufactured by F. Hoffmann-LaRoche and Company.

THYROIDEUM. U. S. Thyroid

[**Thyroid.**—Thyroideum Siccum U. S. P. IX, Desiccated Thyroid Glands]

Thyroid is the cleaned, dried, and powdered thyroid gland, previously deprived of connective tissue and fat. It is obtained from domesticated animals which are used for food by man.

Thyroid contains not less than 0.17 and not more than 0.23 per cent of iodine in thyroid combination, and must be free from iodine in inorganic or any other form of combination than that peculiar to the thyroid gland. One part corresponds to approximately 5 parts of the fresh glands.

Preparation—Selected thyroid glands of the sheep are minced, dried, treated with petroleum benzin to remove fat, dried again, and powdered. The active constituent seems to be an organic combination of iodine, sometimes called *thyroglobulin*, for the iodine content of which the U. S. P. has fixed a standard and assay.

Description and Physical Properties—A yellowish, amorphous powder, having a slight, characteristic odor.

Tests for Purity—Thyroid contains not more than 6 per cent of moisture.

Ash: not more than 5 per cent.

Assay—Mix 1 Gm. of Thyroid in a nickel crucible of about 125 cc. capacity, with 15 Gm. of a mixture composed of 138 parts by weight of anhydrous potassium carbonate, 106 parts of anhydrous sodium carbonate, and 75 parts of potassium nitrate. Spread an additional 5 Gm. of this fusion mixture evenly over the surface. Heat the crucible over a free Bunsen flame until no further carbonization is observed, cool, and dissolve the residue in about 150 cc. of distilled water, warming to hasten solution. Transfer this solution to an Erlenmeyer flask of about 500 cc. capacity, and add approximately 50 cc., or its equivalent, of a fresh solution of chlorinated soda (containing 2.5 per cent of chlorine by weight). Treat the mixture with enough phosphoric acid, diluted with an equal volume of distilled water, to produce an appreciable yellow tint of free chlorine, add about 10 cc. more of phosphoric acid, diluted with an equal volume of distilled water, and boil for one-half hour or until the volume has been reduced to about 150 cc. Cool the liquid, add 10 cc. of a freshly prepared aqueous solution of potassium iodide (1 in 100), and titrate the

liberated iodine with freshly prepared two-hundredth-normal sodium thiosulphate, starch T.S., being used as indicator just before the end of the reaction.

Each cc. of two-hundredth-normal sodium thiosulphate used corresponds to 0.0001058 Gm. of iodine derived from thyroid glands.

This assay is explained on page 1465.

Uses—Desiccated thyroid glands in powder is used in myxedema, for which it may be said to be almost a specific; also in the treatment of cretinism. Dose, one to four grains (0.065 to 0.25 Gm.).

THYROXINUM. U. S. Thyroxin

[Thyrox.]

Thyroxin [$(C_8H_5ONI_3).C_2H_4COOH = 584.90$] is an active principle obtained from the thyroid gland, and contains not less than 63 per cent of iodine.

Description and Physical Properties—White or slightly yellow, needle-like, odorless crystals or powder.

Thyroxin is insoluble in water and practically insoluble in alcohol or other usual organic solvents, but in the presence of mineral acids it dissolves in alcohol. It is soluble in solutions of the alkali hydroxides and when alkaline solutions are saturated with sodium chloride the sodium salt of thyroxin separates.

Tests for Identity—Ignite a few milligrams of Thyroxin with about 0.1 Gm. of sodium carbonate, dissolve the residue in 2 cc. of distilled water, acidulate with acetic acid, add 1 cc. of chloroform and a few drops of chlorine T.S.: the chloroform acquires a violet color.

Tests for Purity—The ash from 0.01 Gm. is negligible.

Dry about 0.02 Gm. of Thyroxin over sulphuric acid for twenty-four hours: the loss in weight is negligible (*water*).

Shake 0.01 Gm. of Thyroxin with 10 cc. of distilled water during five minutes, and filter. Acidulate the filtrate with one drop of diluted nitric acid, and add 3 drops of tenth-normal silver nitrate: the turbidity so produced is not greater than that produced in a control test by one drop of fiftieth-normal hydrochloric acid (*soluble iodides*).

Assay—Mix about 0.02 Gm. of Thyroxin, previously dried over sulphuric acid for twenty-four hours and accurately weighed, with about 0.5 Gm. of anhydrous potassium carbonate in a small platinum crucible. Cover the mixture with an additional 1 Gm. of anhydrous potassium carbonate, and heat gradually until it is completely decomposed. Treat with distilled water and transfer to a 100 cc. graduated flask. Heat the solution on a water bath and add potassium permanganate solution (1 in 20), drop by drop, until the liquid remains pink. Then add, drop by drop, just enough alcohol to discharge the pink color, cool, and dilute to the mark with recently boiled and cooled distilled water. Mix well and filter through a dry filter into a dry flask, rejecting the first 20 cc. of the filtrate. To 50 cc. of the filtrate add about 0.5 Gm. of potassium iodide and 30 cc. of diluted sulphuric acid, and titrate the liberated iodine with two-hundredth-normal sodium thiosulphate, using starch T.S. as indicator towards the end. Correct for any iodine liberated in a blank made with the same quantities of distilled water, sulphuric acid, and potassium iodide. Each cc. of two-hundredth-normal sodium thiosulphate corresponds to 0.0001058 Gm. of iodine.

This assay is explained on page 1465.

Uses—Thyroxin is used essentially for the same purpose as Dried Thyroids, U. S. P., but the dosage may be more accurately determined and results more quickly obtained. It is indicated in cases of diminishing or absent thyroid functioning, such as simple goiter, cretinism and myxedema.

Dose—from 0.2 mgm. to 2 mgm. Thyroxin should always be given in minimum doses and in each case the optimum amount should be determined by trial. For the exact determination of this dose, the establishment of the basal metabolic rate for each given case is necessary.

Thyroxin may be administered either by intravenous injection or by mouth. In those cases in which thyroxin is not absorbed quantitatively when given by mouth it may be given intravenously according to the following directions: Place a known amount of pure crystalline thyroxin—from 1 to 10 mgm.—in a small sterile test tube, such as is used for the Wassermann test. Add 1 drop of 10 per cent sodium hydroxide solution and about 1 cc. of water. Warm and agitate the solution until the crystals are dissolved, and then sterilize by placing the tube in boiling water. Transfer the solution to a sterile hypodermic syringe, rinse out the test tube with 1 cc. of sterile distilled water, which is added to the syringe, and then inject the contents of the syringe intravenously.

Manufactured by E. R. Squibb and Sons.

Thyroxin Crude is also recognized by the N. N. R. It is the partially purified disodium salt of thyroxin, approximately 25 per cent admixed with the acid-insoluble humus-like products of protein hydrolysis.

The uses are the same as those of thyroxin, except that it is not to be used for injection but is administered orally. In certain individuals in whom the thyroxin equivalent is not absorbed quantitatively, the pure crystalline thyroxin should be given intravenously (see under thyroxin).

PANCREAS

The pancreas is a gland having, in general, two functions: (1) it secretes into the intestine a digestive juice containing the enzymes trypsin, lipase and amylase (see *Pancreatin*, page 1175); (2) it secretes into the blood a hormone, insulin, which regulates the process of carbohydrate metabolism. A discussion of this substance follows (see under Insulin).

Oral Administration of Pancreatic Preparations—In diabetes, reliance on the oral administration of the pancreatic preparations thus far prepared has so little justification that such practice merits the most vigorous condemnation. Many reputed antidiabetic pancreatic preparations are on the market with claims that they are effective if taken by mouth. The most widely heralded of them have been subjected to the scrutiny of clinical tests controlled with simultaneous laboratory investigation. None of these thus tested has shown any effect on blood sugar or glycosuria. Completely negative results were obtained when these preparations were given in the doses recommended by their exploiters as well as in doses twenty times as large. The claim that such preparations exert, in some mysterious manner, a rejuvenating or stimulating action on the diseased pancreas is based on uncontrolled clinical observation (N. N. R. 1925).

Unofficial Product from the Pancreas

The following extract from the 1925 N. N. R., on the subject of Insulin, supplies important information which should be available to the pharmacist:

Insulin—Insulin is an aqueous solution of an active principle from pancreas which effects sugar metabolism. The strength of insulin is expressed in "units", one unit being one-third of the amount required to lower the blood sugar to an average of 0.045 per cent over a period of five hours in a normal rabbit weighing 2 kilograms, which has been previously starved for twenty-four hours.

Uses—It has been demonstrated that the administration of insulin to diabetic dogs and to man in severe cases of diabetes mellitus restores to the body the lost ability to oxidize carbohydrate, and that glycogen is again stored in the liver. If insulin is administered at suitable intervals to a person suffering from diabetes mellitus, the blood sugar is maintained at a normal level and the urine remains free of sugar; fat is also burned and as a result, ketone bodies do not appear in the urine and diabetic acidosis and coma are prevented.

The administration of insulin is indicated in cases of diabetes mellitus which cannot be controlled at a satisfactory level by dietetic treatment. In such cases with proper regulation of diet, insulin should be administered in such amounts as to prevent glycosuria and a too great hyperclycemia. In some cases the dosage of insulin may be gradually decreased as the body power of utilizing carbohydrate returns toward normal.

Overdosage of insulin is followed by the development of serious symptoms which demand immediate treatment. The patient complains of weakness and fatigue and a feeling of nervousness or tremulousness. This is followed by profuse sweating, which is the most characteristic sign of overdosage. There is sometimes pallor or flushing. In the more severe forms there is acute distress with mental disturbances and even unconsciousness. These symptoms are relieved by the administration of some form of available carbohydrate by mouth or stomach tube, or, if the patient is comatose, by the intravenous injection of from 5 to 20 Gm. of pure glucose in a five to fifty per cent sterile solution. Physicians treating patients with insulin should be impressed with the necessity of having adequate supplies of sterile solution of glucose at hand. In case of emergency when sterile solution of glucose is not available, a subcutaneous injection of 0.3 cc. to 0.6 cc. of 1 in 1000 solution of epinephrine may be employed, but this must always be followed by carbohydrates by mouth. The injection of epinephrine must be employed carefully as its action depends on the presence of glycogen of which there is usually very little in the diabetic organism.

Dose—Insulin is administered by injection into the loose subcutaneous tissue of the body, usually thirty minutes before meals. There is no average dose of insulin for diabetics; each case must be studied individually. Except when complications occur insulin is not indicated when a patient has adequate glucose tolerance to provide him with a diet sufficient for light work. The dose depends upon the amount of glucose in such a diet as he is unable to metabolize; *i. e.*, the glucose excretion on a known diet. A convenient formula is: $\frac{\text{Average Gm. glucose excreted}}{1.5} = \text{sufficient units of insulin to render most patients aglycosuric.}$ Usually the daily dose is administered in two portions, one before breakfast and the other before supper. The carbohydrate of the diet should be distributed evenly between the three meals. With large daily dosage (40 units or more) insulin should be injected before each meal. When the patient becomes aglycosuric the dose usually can be reduced by one-third. Sufficient should be used to keep the fasting blood sugar normal but hypoglycemia should be avoided. If patients are not under careful control half the estimated dose may be used and the dose gradually increased until therapeutic results are obtained.

In cases of coma or severe acidosis an initial dose of 30 to 60 units may be given (in coma intravenously), followed at 3 to 4 hour intervals by doses of 20 units or more subcutaneously. Administer 1 Gm. of glucose for each unit of insulin used, The patient should never become hypoglycemic. Examine the urine hourly for glucose. If patient becomes sugar free more glucose must be given. More than 150 units of insulin in twelve hours is rarely needed.

In a small number of cases of *diabetes mellitus*, insulin can be discontinued, particularly with patients who receive it because of an exacerbation caused by complications, and where diabetes is of recent onset (though perhaps the latter should receive it intermittently as a prophylactic against increasing severity). Insulin was isolated and its therapeutic value demonstrated by Dr. F. B. Banting, while conducting researches in the University of Toronto. The University maintains full control of the product through patent rights expiring in 1940, but have arranged for its manufacture and distribution by a number of pharmaceutical manufacturers.

OVARY

The ovaries produce internal secretions which are necessary for the proper functioning of the uterus and which also have obscure effects on metabolism and on the nervous system. It is believed that ovarian function is maintained by hormone action, but the hormones themselves have so far not been isolated. While the action of some of the ovarian hormones appears to be exclusively on the organs of the genital tract or on the ovary itself, other hormones appear to have perhaps indirectly a more general influence (basal metabolism, bone-growth, nervous system).

Various preparations of the ovary of animals have been used in the treatment of conditions believed to be due to ovarian dysfunction on the assumption that the preparations contain the active principles or hormones of the ovary. Preparations of the whole ovary, corpus luteum, liquor folliculi and ovarian residue have been employed.

Rational as ovarian therapy may theoretically appear to be in some conditions, the actual results are rarely striking, and often nil to the careful observer. It cannot be assumed that a commercial preparation can replace the normal ovarian secretion in the patient's body, or for that matter that it originally contains any of the active hormones of the ovary. Further, it is not unlikely that whatever activity may be present in ovarian preparations given by mouth, is destroyed by the digestive juices, and there is considerable evidence that the aqueous extracts prepared for hypodermic use are inert. It may also be noted that favorable results interpreted as due to ovarian therapy have most often been reported in conditions in which the symptoms are subjective. Frequently favorable reports have concerned cases in which ovarian products were given together with preparations of the thyroid gland, the activity of which is not destroyed in the digestive tract.

Ovarian Substance-Armour, N. N. R.—The entire fresh ovaries (including the corpora lutea) of the hog, cleaned, dried and powdered, without the addition of either preservative or diluent.
A yellowish powder having a peculiar odor; it is partially soluble in water.
Dose—From 1 to 10 grains (0.06 to 0.60 Gm.), three times daily.
Manufactured by Armour and Company.

Ovarian Substance-L. & F. Desiccated, N. N. R.—The entire fresh ovary (including the corpora lutea) of the hog, freed of extraneous matter, dried and powdered without the addition of diluent or preservative, one part representing approximately 6½ parts of the fresh gland.
A yellowish powder having a peculiar odor, partially soluble in water.
Dose—From 2 to 5 grains (0.12 to 0.3 Gm.).

Ovarian Substance-Wilson, N. N. R.—The entire fresh ovaries (including the corpora lutea) of the hog or cow, mechanically freed from fat, dried and powdered. It contains no diluent or preservative.
A yellowish powder, having a characteristic odor. It is partially soluble in water.
One part represents approximately seven parts of the fresh ovary.
Dose—From 1 to 3 grains (0.06 to 0.2 Gm.).
Manufactured by The Wilson Laboratories.

Whole Ovary-H. W. & D., N. N. R.—Whole ovarian glands of the cow (including the corpora lutea), selected, freed from extraneous matter and dried *in vacuo*.
A yellowish powder, having a peculiar odor. It is partially soluble in water.
One part represents approximately 5 parts of the fresh animal ovary.
Dose—5 grains (0.3 Gm.) or more daily, modified to meet the requirements of the special case.
Manufactured by Hynson, Westcott and Dunning.

Whole Ovary-Lederle, N. N. R.—Whole ovarian glands of the hog or cow, freed from extraneous matter and dried at or below 38° C.
A yellowish powder, having a peculiar odor. It is partially soluble in water.
One part represents approximately 5 parts of the fresh animal ovary.
Dose—5 grains (0.3 Gm.) or more daily.
Manufactured by the Lederle Antitoxin Laboratories.

Ovarian Residue-H. W. & D., N. N. R.—The residue from the fresh ovaries of the hog after the ablation of the corpus luteum.
Ovarian residue-H. W. & D. is a grayish powder, having a characteristic odor.
Uses—Ovarian residue is used for the same conditions as the entire ovarian substance; but it is claimed to have the advantage of being somewhat more stable in composition.
Dose—From 5 to 10 grains (0.3 to 0.6 Gm.).
Manufactured by Hynson, Westcott and Dunning.

Ovarian Residue-Lederle, N. N. R.—The residue from the fresh ovaries of the hog or cow after the ablation of the corpus luteum, dried and powdered, without the addition of preservative or diluent.
One part of ovarian residue-Lederle represents approximately 5 parts of fresh substance.
Uses—Ovarian residue is used for the same conditions as the entire ovarian substance.
Dose—3 grains (0.2 Gm.) or more daily.
Manufactured by Lederle Antitoxin Laboratories.

Ovarian Residue-L. & F. Desiccated, N. N. R.—The residue from the fresh ovary of the hog after removal of the corpus luteum, dried and powdered without the addition of diluent or preservative.
A yellowish powder having a peculiar odor; partially soluble in water.
One part represents approximately 8 parts of the fresh substance.
Dose—5 grains (0.3 Gm.), three times a day, to be increased if required.
Manufactured by Lehn and Fink, Inc.
Capsules Ovarian Residue-L. & F. Desiccated, 5 grains.
Tablets Ovarian Residue-L. & F. Desiccated, 2 grains.
Tablets Ovarian Residue-L. & F. Desiccated, 5 grains.

Ovarian Residue-Wilson, N. N. R.—The residue from the fresh ovaries of the cow after the ablation of the corpus luteum.
A grayish powder, having a peculiar odor.
Dose—1 to 3 grains (0.06 to 0.2 Gm.).
Manufactured by The Wilson Laboratories.

Corpus Luteum-Lederle, N. N. R.—The fresh substance from the corpora lutea of the hog or cow, dried and powdered without the addition of preservatives or diluent.
Dose—2 grains (0.12 Gm.) or more daily.
Manufactured by Lederle Antitoxin Laboratories.

Corpus Luteum-L. & F. Desiccated, N. N. R.—The fresh substance of the corpora lutea of the ovaries of the hog, dried and powdered without the addition of diluent or preservative.

A yellowish powder having a peculiar odor; partially soluble in water.

One part represents approximately 5 parts of fresh substance.

Dose—From 2 to 5 grains (0.12 to 0.3 Gm.).

Manufactured by Lehn and Fink, Inc.

Desiccated Corpus Luteum-Armour, N. N. R.—The fresh substance from the corpora lutea from cows' ovaries, removed, dried and powdered without the addition of preservatives or diluent.

A yellowish powder, having a peculiar odor. It is partly soluble in water.

One part represents approximately 5 parts of the fresh corpus luteum substance. It contains a true lipochrome which may be extracted by alcohol, ether or chloroform.

Dose—From 2 to 10 grains (0.12 to 0.6 Gm.) twice daily.

Manufactured by Armour and Company.

Desiccated Corpus Luteum-Wilson, N. N. R.—The fresh substance from the corpora lutea of the cow, dried, freed from fat and powdered. It contains no diluent or preservative.

A yellowish powder, having a characteristic odor. It is partly soluble in water.

One part represents approximately 5 parts of the fresh corpus luteum substance.

Dose—From ½ to 2 grains (0.03 to 0.12 Gm.).

Manufactured by The Wilson Laboratories.

Lutein-H. W. & D., N. N. R.—The fully developed corpora lutea of the hog freed from foreign material, dried and powdered. One part represents approximately five parts of the fresh substance.

Dose—From 2 to 10 grains (0.12 to 0.6 Gm.), two or three times a day.

Manufactured by Hynson, Westcott and Dunning.

Corpora Lutea Soluble Extract-Wilson, N. N. R.—A sterile solution of those constituents of corpus luteum which are soluble in physiological solution of sodium chloride containing in each cubic centimeter 0.02 Gm. of soluble matter in addition to sodium chloride and chlorbutanol as a preservative.

Uses—See article on the *Ovary*.

Dose—1 cc. daily in extreme cases; less according to individual cases.

Manufactured by The Wilson Laboratories.

Corpus Luteum Extract-Lederle, N. N. R.—A sterile solution of those constituents of corpus luteum which are soluble in water containing sodium chloride 0.85 per cent., sodium citrate 1 per cent and chlorbutanol 0.5 per cent. Each cc. contains 0.02 Gm. of soluble matter in addition to sodium chloride and sodium citrate and chlorbutanol as preservative.

Dose—1 cc. intramuscularly every second day. In severe cases daily doses are said to be indicated.

Manufactured by Lederle Antitoxin Laboratories.

Sterile Solution of Lutein-H. W. & D., N. N. R.—Each cc. contains the water-soluble extractive of 0.2 Gm. of lutein, freed from protein in physiological solution of sodium chloride.

Dose—1 cc. daily, intramuscularly.

Manufactured by Hynson, Westcott and Dunning.

PARATHYROID GLAND

The use of parathyroid preparations has been recommended in the therapy of a large number of conditions. In most cases such use rests on a very flimsy foundation. Generally the reports fail to give conclusive evidence that the substance used contains the hormone of the parathyroid gland. That this gland possesses a hormone is probable. Successful substitution therapy in tetania parathyreopriva has been reported to have been accomplished by use of extracts, emulsions, nucleoproteins and dried gland. So far, no method seems to have been devised for the biologic standardization of parathyroid preparations that are available.

The knowledge that there is a disturbance of calcium metabolism in tetania parathyreopriva has led to the use of parathyroid preparations in various diseases of the bone, such as osteomalacia and rickets. Certain workers who reported successful substitution therapy in parathyroid tetany also reported successful administration of parathyroid in the treatment of gastric tetany, which does not depend on a parathyroid deficiency but on an entirely different mechanism. One must look askance at such reports until there is a preparation shown to contain the active principle of the parathyroid gland (if such exists), susceptible of successful use in substitution therapy after adequate removal of a parathyroid tissue and also of being biologically standardized.

To devote the space required to enumerate the entire list of conditions in which the use of parathyroid therapy has been proposed does not seem justifiable in view of the meager evidence of its value. There appears to be no single condition for which the use of parathyroid therapy rests upon a firm foundation, except the use of auto-transplants, in tetania parathyreopriva.

Desiccated Parathyroid Gland-Armour, N. N. R.—The exterior parathyroids of the ox freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A light yellow powder having a peculiar odor. Partly soluble in water.

One part represents approximately 10 parts of the fresh tissue.

Dose—$\frac{1}{15}$ grain (0.006 Gm.), four times a day.

Manufactured by Armour and Company.

Desiccated Parathyroid Substance-Wilson, N. N. R.—The exterior parathyroids of the ox freed from fat, cleaned, dried and powdered, without the addition of preservative or diluent.

A light yellow powder having a characteristic odor. One part represents approximately 5 parts of the fresh tissue.

Dose—$\frac{1}{20}$ to $\frac{1}{10}$ grain (0.003 to 0.006 Gm.) as often as directed.

Manufactured by The Wilson Laboratories.

FIBRIN FERMENTS

The following information concerning these important new therapeutic agents is an abstract from the 1925 N. N. R.:

Preparations containing thromboplastin are said to be useful when applied locally in the treatment of hemorrhages, especially hemorrhages from oozing surfaces, scar tissues and in nose bleed, and in surgery of the bones, glands, nose, and throat. When injected subcutaneously or intravenously, such preparations are said to shorten the coagulation time of the blood for a period of about twenty-four hours, but there may be a certain danger of a negative phase setting in. Such injections are contraindicated in cases in which there is a

tendency to thrombosis or embolism; for example, in arteriosclerosis, aneurysm, heart weakness, phlebitis, certain stages of syphilis, and in varicose veins. Preparations should be standardized by testing on specimens of blood in vitro, which should be able to bring the coagulation time to about one third of its original length; they should be proved to be sterile, particularly if intended for intravenous use.

Brain Lipoid, N. N. R.—*Impure Cephalin*—Impure Kephalin—An ether extract of the brain of the ox, or other mammal, prepared according to the method of Howell (see the N. N. R.).

Dose—Brain lipoid may be smeared on gauze sponges, pledgets, or on the tissues themselves; or an emulsion may be prepared by shaking up with physiological solution of sodium chloride and used in the same way or sponged over the tissues.

For use in an office or dispensary, the ether extract suffices and can be kept ready for use for some time (several months) in a sterile dropper bottle from which an opalescent emulsion can be prepared at a moment's notice by dropping from 10 to 30 drops into an ounce of physiological solution of sodium chloride and then shaking. This solution can also be dispensed from drug stores, provided the opening in the stopper of the dropper bottle is kept slightly open to prevent the ether's blowing off when the bottle is shaken or heated.

Kephalin-Armour, N. N. R.—The hemostatic phosphatid obtained from the brain tissue of cattle. It is essentially the same as brain lipoid.

Dose—From 0.1 to 0.2 per cent suspensions of kephalin-Armour in sterile physiological solution of sodium chloride are applied freely to bleeding or oozing surfaces.

Manufactured by Armour and Company.

Solution Brain Extract, N. N. R.—*Liquor Extracti Cerebri*—Solution Thromboplastin-Hess—An extract of cattle brain in physiological solution of sodium chloride prepared by the method of Hess (see the N. N. R.).

Dose—The solution may be applied directly to the bleeding tissues or sprayed on them, or a sponge or tampon may be immersed in it and then pressed on the bleeding surface.

Thromboplastin Solution-Armour, N. N. R.—An extract of cattle brain in physiological solution of sodium chloride prepared according to the method of Hess.

Dose—See Solution Brain Extract. Thromboplastin solution-Armour is marketed in 25-cubic-centimeter vials which bear an expiration date, after which time the contents should not be used.

Manufactured by Armour and Company.

Thromboplastin-Lederle, N. N. R.—An extract of cattle brain in physiological solution of sodium chloride prepared according to the method of Hess.

Dose—For local application, see Solution Brain Extract. When local application is not possible, 10 to 20 cc. may be injected subcutaneously or intramuscularly. Thromboplastin-Lederle is marketed in 20 cc. vials which bear an expiration date, after which the contents should not be used.

Manufactured by Lederle Antitoxin Laboratories.

Thromboplastin-Squibb, N. N. R.—An extract of cattle brain in physiological solution of sodium chloride prepared according to the method of Hess.

Dose—See Solution Brain Extract. Thromboplastin-Squibb is marketed in 20-cubic-centimeter vials. It is claimed that no loss of potency could be detected in unopened specimens of thromboplastin-Squibb more than two years old.

Manufactured by E. R. Squibb and Sons.

Thromboplastin Hypodermic-Squibb, N. N. R.—A sterilized extract of cattle brain in physiological solution of sodium chloride. It complies with the description of thromboplastin-Squibb, but a longer time is required for the clotting of blood plasma.

Actions and Uses—Thromboplastin hypodermic-Squibb is intended for hypodermic and intramuscular injection to increase the coagulability of the blood.

Dose—From 10 cc. to 20 cc. every twenty-four to seventy-two hours. Thromboplastin hypodermic-Squibb is marketed in 20-cubic-centimeter vials which bear an expiration date after which time the contents should not be used. (The manufacturer reports that no loss of potency could be detected in specimens which had been kept unopened for two years.)

Manufactured by E. R. Squibb and Sons.

OTHER PRODUCTS OF ANIMAL ORGANS

Mammary Substance—The mammary gland of the sheep cleaned, dried and powdered. Used to control uterine hemorrhage and induce contraction of the uterus after labor.

Dose—2 to 5 grains (0.13 to 0.32 Gm.).

Pineal Gland (Desiccated)—The pineal gland, a small, reddish, vascular body in the posterior part of the third ventricle, of normal young cattle, cleaned, dried, and powdered. It has some influence on the growth of the body and mental development. Used in the treatment of undersized and mentally backward children.

Dose—$\frac{1}{10}$ grain (0.006 Gm.).

Thymus Gland (Desiccated)—A glandular organ in the anterior superior mediastinium (the septum of the thorax cavity). It disappears in adult life. It is prepared by drying the thymus gland obtained from healthy domestic animals. It is used much like the thyroid in the treatment of exophthalmic goiter, also in rickets, marasmus, and related diseases.

Dose—2 to 4 grains (0.13 to 0.25 Gm.).

Testicular (Orchic) Substance—The testes of the hog or cattle, cleaned, dried and powdered.

Unofficial Animal Products and Derivatives

Class Mammalia

Acidum Butyricum, $C_4H_8O_2$ Butyric Acid	A colorless liquid, having a disagreeable odor and a rancid taste. Density, 0.973
Ambra Grisea Ambergris	A morbid excretion from the intestines of *Physeter macrocephalus*, found floating on the sea. It is friable when cold, of a gray or brown-gray color. It contains 85 per cent of ambrein, etc. Used in perfumery
Argenti Lactas, Silver Lactate $Ag.C_3H_5O_3 + H_2O$	The normal silver salt of lactic acid. An astringent antiseptic, having about twice the power of mercuric chloride. It is irritating if applied in substance to wounds. Used in 1 : 100 to 1 : 2000 solutions
Argonin	Silver-casein. A white powder containing from 4 to 25 per cent of silver. Used as injection in 2 to 5 per cent solutions

Unofficial Animal Products and Derivatives—*Continued*

Sanguis Blood	The arterial fluid of the ox, *Bos taurus*. It is of a red color, opaque, and has a peculiar odor. It contains 78 per cent of water, 8 per cent of albumen, 5 per cent of fibrin, etc. The red color is due to *hæmoglobin*
Butyrum Butter	From the milk of the cow, *Bos taurus*. Obtained by allowing the cream to separate from the milk, collecting and churning. A soft, yellow, neutral substance, of a pleasant, sweet odor and a bland taste. It contains 30 per cent of olein, and about 68 per cent of palmitin and stearin, etc.
Castoreum Castor	From the preputial follicles of both the male and female animals *Castor Fiber*. They occur in pairs, are pyriform, of a brown or blackish color, a peculiar odor, and a bitter, acrid, and nauseous taste. It contains a volatile oil, and from 15 to 40 per cent of a bitterish, resinous substance, etc.
Civetta Civet	An odorous substance obtained from two animals of the genus *Viverra* which inhabit the East Indies. It is semi-solid, unctuous, yellowish, becoming brown and thicker by exposure to air; of a very strong, peculiar odor and a bitterish acrid, and nauseous taste. It contains volatile oil, and resinous and other matters. Used in perfumery
Collargolum Argentum Credé	Colloidal or soluble silver. Dose, 1 to 2 grains (0.065 to 0.13 Gm.)
Fibrin	Obtained when blood is allowed to coagulate or is whipped with a bundle of twigs. It is at first, when pure, a gelatinous mass, which changes to a white, tenacious material, consisting of minute fibrils
Hemoglobin	The coloring matter of the red blood corpuscles combined with iron. Used as a substitute for iron in the treatment of anemia. It consists of protein, globulin, and hematin. Various preparations of hemoglobin have been put on the market. These are of two classes: (1) preparations consisting essentially of oxyhemoglobin, usually sold under the name "hemoglobin"; (2) preparations derived by the action of reducing agents on the blood, such as zinc and pyrogallol. They consist of reduced hemoglobin or of some modification of it
Hemogallol (Hæmoglobin, deoxidized by pyrogallol)	A combination of iron with the hemoglobin of blood; a compound which is easily assimilated. In the form of an insoluble and tasteless red-brown powder. Given in doses of 4 to 8 grains (0.25 to 0.5 Gm.) for anemia, convalescence, etc.
Hemol	A blood preparation containing iron
Hyraceum	The product of *Hyrax capensis*, an animal of Southern Africa. It is found on the rugged sides of mountains, and is supposed to be the excrement or the dried urine of the animal. It is rather hard, tenacious, of a blackish-brown color, and of a taste and smell similar to those of castor
Keratin	The organic basis of horny tissues, hair, nails, feathers, epithelium, etc. It has been used for coating pills so as to enable them to pass through the acid juices of the stomach and be dissolved in the alkaline intestinal fluids, but has been largely discredited
Milk Casein	The most abundant of the albuminoids obtained from milk by the addition of rennet
Moschus Tonquin Musk (U. S. P. IX)	The dried secretion from the preputial follicles of *Moschus moschiferus* Linné (Fam. *Moschidæ*) Usually in small irregular granules not more than 2 mm. in thickness, blackish with a few brown fragments and becoming somewhat grayish on aging; glistening and somewhat oily. Odor peculiar, penetrating, powerful and persistent; taste somewhat bitter. Its aqueous solution is slightly acid to litmus. (See the U. S. P. IX for additional tests for purity.) Musk contains cholesterol, ammonia, an acid principle, wax, fat, albuminous and gelatinous principles, and an odorous matter not yet determined Uses—Musk is antispasmodic and stimulant. It is used in the form of suppositories as a stimulant in the exhaustion of typhoid fever. Dose, 4 to 15 grains (0.25 to 1 Gm.). The largest use of musk has been as a fixative in perfumes (see page 1218) but its scarcity and high cost necessitate many substitutes which have largely replaced it. Its use in medicine has also been largely discontinued
Neat's-foot Oil	Prepared by boiling the feet of cattle, deprived of their hoofs, with water, removing the oil which rises to the surface, and allowing it to remain for some time in warm water. Used for softening leather
Novargan Argenti Proteinas	An organic silver-albumin compound containing 10 per cent of silver. It occurs in fine yellow powder, soluble in water. It is a bactericide, and less irritating than other protein-silver compounds. Used in gonorrhea, especially as an abortive in the first stage. Dose, 8 minims (0.5 cc.) of a 15 per cent solution
Ovoferrin	A solution containing 5 per cent of an artificial protein product in which iron is present in the so-called "organic" or "masked" form (a form which does not give the iron test directly) equivalent to 0.4 Gm. of metallic iron to each 100 cc. Ovoferrin is prepared by modifying serum albumin by electrolysis and introducing ferric hydroxide into this modified protein by heating under pressure The solution has a reddish-brown color, little odor, and a flat, slightly aromatic and alcoholic taste[1] Ovoferrin is said not to be affected appreciably by the gastric juice, 0.5 per cent solution of hydrochloric acid liberating its iron very slowly and incompletely. The product ranks with the other forms of artificially masked iron, which are devoid of the local action of the soluble inorganic iron salts, and, according to some authorities, are more readily absorbed and utilized. Dose, from 2 to 4 fluidrachms (8 to 15 cc.) corresponding to from ½ to 1 grain (0.03 to 0.06 Gm.) of elemental iron, three times a day Manufactured by A. C. Barnes Company
Paraglobulin	Obtained from blood serum, lymph, chyle, etc. It is a granular substance, gradually becoming more compact
Peptones	The product of the action of gastric and pancreatic juices, or of pepsin alone, upon albuminoids during the process of digestion
Ptomaines Cadaveric alkaloids	Alkaloidal substances found in dead bodies or decomposed animal matter, as *cholines, muscarine, neurine, gadinine, tetanine, dimethylamine, trimethylamine, triethylamine, putrescine, cadaverine, saprine, neuridine, collidine, hydrocollidine, parvoline,* and *tyrotoxicon (diabenzene)*, etc.

Unofficial Animal Products and Derivatives—*Continued*

Ptyalin	A fermentative substance occurring in saliva, and having the power of converting starch into dextrin
Sodii Choleas Sodium Choleate	Prepared by evaporating fresh oxgall to one-half, and precipitating the slimy and coloring matters with an equal bulk of alcohol, treating the filtrate with animal charcoal, distilling off the alcohol, and washing the residue with ether. It occurs as a white, sticky mass, having a penetrating odor, and a peculiar, sweetish, afterwards bitter taste. (See Fel Bovis)
Sophol	A compound of silver and methylene-nucleinic acid, the silver being in organic or masked form. A bactericide used in eye affections. Use from 2 to 5 per cent solutions
Urea, Carbamide, $CO(NH_2)_2$	A hydragogue diuretic. Dose, 10 grains (0.65 Gm.) every six hours
Sperm Oil	From the cranial cavities of *Physeter macrocephalus*. It is of a yellow or brown-yellow color. Sp. gr. 0.920. On cooling, it deposits spermaceti and stearin
Whale Oil	From *Balæna mysticetus*. It has a peculiar fishy odor and unpleasant taste
Porpoise Oil	From *Delphinus Phocæna*. Prepared by heating the belly-blubber of the porpoise. It is, when fresh, of a pale yellow color
Seal Oil	From *Phoca* of various species
Dugong Oil	From *Halicore Dugong*. Habitat, waters of Eastern Australia. This oil is generally used as a substitute for cod liver oil in Australia
Class Pisces	
Eulachon Oil	From *Thaleichthys Pacificus*, a small fish found on the Pacific Coast. This oil has been proposed as a substitute for cod liver oil
Gaduol (Morrhuol)	Alcoholic extract of cod liver oil. Brownish-yellow, oily liquid of a bitter, acrid taste. Used like cod liver oil, prepared in wine or elixirs, in doses of 5 to 30 minims (0.3 to 2 cc.)
Ichthyocolla Isinglass. (U. S. P. 1890)	The swimming bladder of *Acipenser Huso* Linné, and of other species of *Acipenser* (order *Sturiones*). Used in making isinglass or court plaster
Menhaden Oil	From *Alosa Menhaden*. Habitat, Atlantic Coast. Used in dressing leather
Shark Oil	From the liver of the shark, *Squalis Carcharias*, and other species. It is of a light yellow color, and has an acrid taste. Sp. gr. 0.870 to 0.880
Skate Oil	From the liver of *Raja Batis*. Employed largely in France and Belgium. It is of a bright yellow color. Sp. gr. 0.928
Lipanin	A mixture of 100 parts of olive oil and 6 parts of oleic acid. Used as a substitute for cod liver oil. Dose, 1 to 4 fluidrachms (4 to 16 cc.)
Class Aves	
Ferratin Ferric Acid Albuminate	A reddish-brown, odorless, and tasteless powder, insoluble in water, but soluble in slightly alkaline solutions. It contains about 7 per cent of iron, and is given in eight-grain (0.5 Gm.) doses
Ingluvin	From the gizzards of *Gallus Bankiva*. Prepared by a process similar to that employed in preparing pepsin. The dried and powdered gizzards are often used as digestives
Lecithin, $C_{44}H_{20}NPO_9$ Distearin-Glycero Phosphoric-Cholin Ester	A phosphated substance, prepared from the yolk of egg, nerve tissue, blood, and bile. A colorless, crystalline compound, soluble in alcohol and ether. Used as a nerve tonic in doses of 1 to 2 grains (0.065 to 0.13 Gm.)
Vitellin	It exists in the yolk of eggs. Closely resembles fibrin
Class Insecta	
Cobweb	The web of *Tegeneria domestica*. It has been recommended in phthisis and chronic intermittents, but is most useful in controlling hemorrhage by simply applying it to the bleeding surfaces
Blatta Cockroach	The insect *Blatta orientalis*, about one inch long, oblong, flat, of a reddish-black color, odor very disagreeable. It contains fetid oil, extractive, antihydropin, etc. Used as a diuretic
Red Ant	The insect *Formica rufa*. It contains a volatile oil and formic acid
Class Reptilia	
Crotalus	Prepared from the venom of the rattlesnake (*Crotalus horridus*). While the snake is under chloroform the poison contained in the fang is pressed out and mixed with 9 parts of glycerin. Used in epilepsy
Phynin	From the glandular secretion and dried skin of the toad (*Bufo viridis* and *B. cinereus*). Similar in its effects to digitalin
Class Annelida	
Hirudo Leech (Br. 1914)	From *Hirudo medicinalis* and *Hirudo quinquestriata*. From three to six inches long, smooth, soft, round, tapering at the ends, composed of about one hundred rings; of a blackish-green color. Used for local depletion

PART VI

PERFUMERY AND COSMETICS

CHAPTER LXXVI

THE ART OF PERFUMERY

IN the cultural development of civilization one of the qualities which lifts mankind above other living things is that esthetic sense of mind and spirit which is expressed by the so-called "fine arts".

To those who will to see is given the delight of nature's glories expressed in mountain, sunset and sea, and in a thousand other beautiful pictures. Man, in sculpture, painting, textile arts, and architecture, has also learned to create beauty and to delight in it. For the ear, great artists have sung their melodious dreams, perpetuating them in music for the stirring of the human heart; for the lifting of nations into realms of sheer delight, or inspiring them to noble deeds. The epicurean artist has brought beauty and joy by his creations. Through the touch of silk and velvet, another sense has brought to man an appreciation of the beautiful. Truly it was ordained that the sense of smell should also bring its gifts; for what is more delightful than the perfume-laden air which drifts across a field of new-mown hay, or the odor of the pine woods, or the faint perfume of a rose or other fragrant flower.

The enjoyment of fine odors has not received the cultivation that is given music, or painting, or the textile arts; yet it plays an important rôle in the lives of most people, influencing actions and giving pleasure, or perhaps distress.

Piesse records the historic fact that in 1770 an act was introduced into English Parliament which read:

> "That all women of whatever age, rank, profession, or degree, whether virgins, or widows, that shall, from and after such Act, impose upon and betray into matrimony any of his Majesty's subjects, by the scents, paints, cosmetic washes, artificial teeth, false hair, Spanish rouge, iron stays, high-heeled shoes, bolstered hips, shall incur the penalty of the law now in force against witch craft and like misdemeanors, and that the marriage, upon conviction, shall stand null and void."

What one has not felt the power of that distinctive perfume which means a presence or a precious memory? What woman does not know the advantage of associating romance with a pleasing perfume and then perpetuating its memory by allowing the capture of a glove or lacy handkerchief which bears the perfume?

Some one has said that no sense brings so vividly to mind its associations as that of smell; most individuals can bear testimony to this truth.

Those who cater to the feminine taste in perfumes should know these facts. It is the distinctive odor, obtainable in every form, suitable for use among the lingerie, for perfuming the bath, or perhaps ready to delicately permeate a room with its sweetness, that will please "milady".

For this is needed the artist's touch, imagination, and the product of the master perfumer.

Perfumes are associated in the earliest records with religious ceremonies. It is but natural that the nations of the East, even in remote antiquity, should have offered the sweet-smelling woods and resins of their native land as gifts to their gods. Thus did they show their homage and respect.

Upon the Egyptian Sphinx which formed the end of a temple, is pictured the king burning incense and offering a libation of oil or ointment.

In Greek mythology men are pictured as obtaining their knowledge of perfumes through the indiscretion of a nymph of Venus.

The early use of perfumes in the worship of the Hebrews is indicated by many passages of the Bible, and in the thirtieth chapter of Exodus, Moses is directed to burn perfumed gums and woods upon an altar, and Aaron to "Burn thereon sweet incense every morning"; Moses is directed also to "take sweet spices, stacte and onycha, and galbanum, these pure spices with frankincense", and to "make perfume, a confection, after the art of the apothecary, tempered together, pure and holy", and "whosoever shall make like unto that, to smell thereto, shall even be cut off from his people".

India and Arabia have traditionally been the lands of perfumes, and the Greeks, and later the Romans also became devotees of the perfumer's art, soon adapting it to their personal use and carrying the practice to an extreme never since attempted.

In Greece the perfumer's shop was the common meeting place for gossip, and a Greek poet of 350 B.C. wrote:

> "For he t' annoint himself,
> Dipped not his finger into alabaster,
> The vulgar practice of a former age;
> But he left fly four doves, with unguents drenched,
> Not of our sort, but every bird a perfume bore.
> Peculiar, and, differing from the rest;
> And they hov'ring around us, from their heavy wings
> Showered their sweets upon our robes and furniture,
> And I—Be not too envious, gentlemen,—
> I was bedewed with violet odours".

In the Roman amphitheater during a spectacle the air was constantly refreshed by the playing of fountains of perfumed waters.

Perfumed ointments were kept in highly ornamented boxes usually made of alabaster or onyx, and a treatise on the perfumer's art, written by Apollonius, is still extant and gives the sources of supply and the uses of the various odors.

A perfume invented by Frangipanni, one of the earliest Roman nobles, is yet used and bears his name. It is a sachet composed of equal parts of "every known spice", to which is added a weight of orris root equal to the whole, and one per cent of musk and civet.

It is supposed that the Crusaders brought the perfumer's art to England from Eastern Lands, and by the Elizabethan period it had been developed to a high degree of perfection.

Beau Brummel, the arbiter of English fashion, did not believe in men of fashion using perfumes, and recommended that they send their linen to be washed on Hampstead Heath.

At the close of the nineteenth century, the manufacture of perfumery had been well established; immense laboratories were built in France and England, and their products sold throughout the world.

Source of Natural Perfumery Materials—The raw materials available at that time were all from natural sources. A number of *animal products* had come into use, not for their value as perfumes, but to perform a necessary function

in the perfume, namely to retard the lavish expenditure of odor which the plant or product would otherwise freely give until exhausted.

This class of products are termed "*fixatives*", and include such substance as musk, ambergris, civet, and castor. These materials are still used, although musk and ambergris are scarce and expensive, and other products have successfully replaced them in many instances.

Natural *perfumed woods or flowers* represent another class of natural products used throughout the centuries, and still employed for sachets. The most important available today are sandalwood, orris, rose petals, cassie flowers, orange flowers, and vertivert.

The oleoresins of Siam benzoin, of oak moss, Peru balsam, tolu, galbanum, orris, styrax, etc., constitute another type of preparations which are still used.

Volatile Oils—The perfume of flowers, fruit, and other natural products is due chiefly to a substance called *volatile oil*. This oil exists in the cells of the plant, and its extraction is accomplished by one of several ways. Some oils, notably those of the citrus group, including orange and lemon, are found in comparatively large cells, near the surface of the rind, and may be readily removed by one of the processes described on page 952.

Other volatile oils may be obtained by what is termed "steam distillation". The oil-bearing portion of the plant, whether fruit, seed, flower, or herb, is placed in a basket in a still. Water is added and the mixture heated, the vapor being condensed and collected in a Florentine receiver. This vessel is so arranged that the lighter oil may separate and rise to the surface for collection, while the saturated water is drawn off at the bottom (see page 215). The water thus obtained is sometimes of commercial value, as orange flower water and rose water, but, if not salable, it is returned to the still for the next operation, and thus the loss of oil is avoided. Today vacuum stills are usually employed in the manufacture of volatile oils (see Fig. 142).

The more important volatile oils made by this process, and of value to perfumery are rose, neroli, lavender flowers, bay, cardamom, cinnamon, rose-geranium, orris, palmarosa, petit-grain, sandalwood, ylang-ylang (see also the chapter on Volatile Oils, page 950).

Pomades—Some volatile oils, especially the more delicate flower perfumes, cannot be obtained successfully by steam distillation, either because the oil exists in quantities too small to distil or it is injured by the process, through oxidization or hydrolysis.

Other processes have therefore been devised. One of these is termed "*enfleurage*" or the "*absorption method*". A mixture of specially selected and highly purified lard and beef fat is spread in a thin layer on linen in a frame, and the fresh flowers, each morning for thirty days, are sprinkled on the fat, the frames being stacked on each other for the intervening time, that the odor may be absorbed. The odorous fat or "*pomade*" as it is termed is later washed with alcohol to remove the perfume, and these *essences* or alcohol washings were, for many years, the most important perfume material available.

The flowers best extracted by the enfleurage process are: jasmine, tuberose, jonquil, lily of the valley (muguet), and mignonette (reseda), and pomades of rose, cassie, violet, orange flowers, lilac, and heliotrope are also obtainable.

The maceration or *infusion process* is also employed for this same group, the fresh flowers, each day, being tied in linen bags and macerated in the warmed fat for twenty-four hours, the flowers being afterward separated from the fat by centrifuging. The fat should be macerated with at least fifteen different lots of flowers. The pomades, especially jasmine, are used particularly to cover the so-called "chemical odor" of synthetics.

Concretes and Absolutes—The group of flowers, which cannot be distilled, are also extracted by cold, *volatile-solvents*, chiefly ether or benzin (petroleum ether), and after extraction the solvent is removed by vacuum distillation. By this cold extraction process are formed what are called "*concretes*". The flowers satisfactorily treated by this method are: rose, Parma violets, victoria violets, orange blossoms, jasmine, tuberose, jonquil, cassie, mignonette, and sometimes carnations, lily of the valley, heliotrope, elder flowers, narcissus, and mimosas.

The volatile-solvent method of extraction removes not only the volatile oil, but also the flower waxes and other inert constituents. If these are now removed by alcohol washing and freezing, a still more concentrated product results, commercially sold under various names such as "*hyperessences*", "*absolutes*", etc., and these are the most expensive perfumery materials now available, the current price for jasmine absolute being $600 a pound. A dilution of this absolute which corresponds exactly in concentration to the concrete is known commercially as a *liquid absolute*. These are made by diluting absolutes to the proper concentration, using an appropriate solvent such as benzyl benzoate or diethylphthalate. Perfumers who use this class of raw materials, obtainable only from the fresh flowers, are apparently justified in the high price asked for their products.

Synthetic Perfumery Material—The cost and variability, in both quality and price, of perfumery products from natural sources, has stimulated the organic chemist to search for synthetic products which would either replace or augment natural perfumes.

The painstaking efforts which have been made to determine the physical characteristics and chemical constituents of important volatile oils and other odorous products, that standards for pure products might be established, and the careful analysis of many other products, in pure research and for commercial purposes, has made available a vast amount of knowledge covering the constituents of these perfumes. With an exact record of the pure chemicals composing the perfume and the proportion in which they exist in nature, the organic chemist theoretically is only required to prepare the various pure chemicals, mix them in the proportion indicated, and produce artificially a rival of nature, which is always uniform in quality and odor-value, and at a price subject to little fluctuation.

This dream of the synthetic chemist has today been partly realized. Many natural oils have been almost completely duplicated in the laboratory, and the chemist has also discovered chemicals which possess odors practically identical with those in nature, but entirely unrelated chemically. Artificial musk admirably illustrates this type (see page 1218).

The perfume chemist has also been able to reproduce many flower odors, which it has not been possible to extract from the flowers because of the minute quantity present; such odors as arbutus and sweet pea are illustrations.

It must not be thought, however, that synthetic perfumes always fully duplicate nature's odors. Often there are minute quantities of constituents which are so elusive that they escape the most careful analysis and others have defied reproduction, but sufficient has been done to fascinate and awe those who make even a casual study of modern laboratory creations, and to very largely replace natural perfumery products.

Aromatic Chemicals Employed in Perfumery—The following section includes the more important of the chemical substances synthetically produced or isolated from natural sources and available today for the preparation of synthetic perfumes. By consulting the advertising pages of a journal like

The American Perfumer, available manufacturers or distributors of these products will be noticed. The various constituents of volatile oils and of flower odors represent many classes of organic compounds and for convenience they are grouped according to their chemical affiliations. For a more complete study of the chemistry of these products see *The Chemistry of Essential Oils* by Ernest J. Parry.

ACIDS

Benzoic Acid—(See page 832). This is used as a fixative in sachets and fumigating pastiles, especially the natural acid separated from *benzoin*. The Siam variety of benzoin is preferred for this purpose. For making *benzoin lotion*, however, the Sumatra benzoin, which contains more gum, is better.

Cinnamic Acid—It is obtained chiefly from storax. White, odorless crystals, melting at 133° C. It is used chiefly as a fixative, especially in its natural combination in storax, benzoin, or tolu.

Phenylacetic Acid—White, flake-like crystals, melting at about 76.5° C. and boiling at 141° C.; soluble in water. It is used chiefly to produce its alcohol or esters but has a honey-like odor and is used to perfume soaps. It is an excellent fixative, replacing indol and civet in perfumes which must be colorless, and in lotions and toilet waters. Use small amounts as it is very powerful.

ALCOHOLS

Alcohol-C_8 (octyl alcohol)—A normal alcohol having a peculiar, fatty odor resembling rose pomade. It is used in toilet water, perfumes, and skin creams, and in fancy floral perfumes of the rose type to get the pomade effect.

Alcohol-C_9 (nonyl alcohol)—A liquid having an odor suggesting oil of tuberose, cassie, mimosa, and jonquil. It is sometimes used to give a special note to rose perfumes or to Cologne water.

Alcohol-C_{10} (decyl alcohol)—A liquid, which when used in small quantities, improves and gives distinctive characteristics to perfumes. Its own odor suggests tuberose or cassie, but is not as strong as Alcohol-C_9. It is also a valuable fixative.

Alcohol-C_{11} (undecylic alcohol)—A liquid occurring naturally in oil of rue but also prepared synthetically. Its odor suggests flowers, principally fresh reseda, cassie, or violet. It is sometimes used in Cologne water.

Alcohol-C_{12}—A solid substance at normal temperature having a weak, fatty, and mellow odor, not very distinctive, but used sometimes to impart the pomade character to floral synthetic odors.

Benzyl alcohol—A colorless liquid, having a slight balsamic odor when pure. It boils at about 295° C. and has a specific gravity of about 1.05 at 15° C. It occurs naturally in the oils of jasmine, neroli, ylang-ylang, cassie, and others, but is prepared synthetically by heating benzyl chloride with potassium carbonate. It is largely used as a solvent and fixative in synthetic perfumes such as jasmine, tuberose, chypre, ylang-ylang, etc. It is also used as a solvent for synthetic musk. Protect from light and air.

Borneol—An alcohol naturally existing in and the characteristic constituent of pine needle oils. It forms a white, crystalline mass which, when pure, melts at 203° C. It is usually found in the form of its esters of which *bornyl acetate* is the most important.

Cinnamic alcohol—Usually a white solid mass when melted, boiling at 117° C. (5 mm.). Soluble in all proportions in alcohol. It occurs naturally as esters, in balsam of Peru and in storax. It possesses a very sweet odor resem-

bling hyacinth or lilacs. It is used chiefly as a fixative in such perfumes as rose, lilac, hyacinth, etc. It is also used as a fixative in creams and in fine soaps.

Citronellol (*roseol, reuniol*)—A colorless liquid, isomeric with rhodinol and geraniol. It boils between 113° and 115° C. (15 mm.); specific gravity 0.86 at 15° C. Soluble in alcohol in all proportions. It occurs naturally in the oils of geranium and rose and the odor is suggestive of both oils. It is used in all rose and geranium perfumes, whether for extracts, soaps, or creams.

Geraniol—A colorless liquid, boiling between 110° and 111° C. (10 mm.); specific gravity 0.88 at 15° C.; an isomer of linaloöl. It is soluble in alcohol in all proportions. It occurs naturally in the oils from palmarosa, citronella (Java), lemon grass and many other oils. Its odor is very sweet and rose-like and it may be used in soaps, as it is not decomposed by free alkali. It is used in many perfumes besides rose, such as geranium, cassie, hawthorn, lily, honeysuckle, neroli, ylang-ylang, etc.

Linaloöl (*linalol*)—A colorless liquid, boiling between 70° and 71° C. (4 mm.); specific gravity 0.87 at 15° C.; an isomer of geraniol. It is soluble in alcohol in all proportions. It occurs naturally in the oils of jasmine, ylang-ylang, bois de rose, rosewood, etc., the latter being the commercial source. The odor resembles rosewood and is used in the preparation of synthetic oils of orange flowers, rose, lily of the valley, lilac, honeysuckle, wallflowers, cyclamen, and other bouquets. The odor is fine but not very lasting.

Nerol—An isomer of geraniol occurring in the free state or as an ester in the oils of neroli, rose, ylang-ylang, wallflower, etc.

Phenylethyl alcohol—Boiling point 99° C. (6 mm.); specific gravity 1.020 at 15° C. A colorless liquid occurring naturally in rose flowers. The odor is honey-like. As it is readily soluble in water, it is found in rose water and only in small quantities in the distilled oil of rose. It is a constituent, however, in rose absolutes and concretes and is the distinctive odor of white rose. It is suitable for perfuming soaps and is employed in the preparation of synthetic oils of rose, lilac, hyacinth, jasmine, narcissus, neroli, lily of the valley, etc. It is also a valuable fixative.

Rhodinol—This alcohol is isomeric with citronellol and geraniol. It is a colorless liquid, boiling between 110° and 120° C. (10 mm.); specific gravity 0.87 at 15° C. The commercial product is usually distilled from geranium oil. It has a strong rose-like odor and is one of the most important constituents in natural oil of rose and oil of geranium and the chief dependence in making artificial oil of rose. It is especially valuable in perfuming toilet soaps.

Terpineol—A colorless liquid, boiling between 104° and 105° C. (10 mm.); specific gravity 0.94 at 15° C. This alcohol possesses an odor resembling the perfume of lilac flowers, and is largely used as a cheap soap perfume, as it is not decomposed by alkali. It is an important addition to the preparation of the cheaper synthetic perfumes of lilac, lily of the valley, sweet pea, violet, carnation, narcissus, etc. It readily dissolves in fats and is therefore much used in toilet creams.

ALDEHYDES

Aldehyde-C_8 (*octyl aldehyde*)—A natural aldehyde in the oils of lemon, rose and neroli. It possesses a strong fatty and waxy odor and must be used only in small amounts. It furnishes a distinctive shade to the odor of fine perfumes, especially of the rose type.

Aldehyde-C_9 (*nonyl aldehyde*)—An aldehyde occurring in the oils of rose, cinnamon and orris. It is of value in preparing synthetic oils of rose and neroli. Only a small amount is to be used, not more than 1 per cent, dissolved in alcohol. It is a good fixative.

Aldehyde-C_{10} (decyl aldehyde)—This is an oily liquid of an intensely sweet odor and used in minute amounts to perfect many synthetic oils including violet, neroli, cassie, rose, jasmine, wallflower, etc.

Aldehyde-C_{11} (undecylic aldehyde)—A liquid having a powerful, undefinable odor. Only traces must be used to modify floral oils.

Aldehyde-C_{12} (lauric aldehyde)—When of full strength it possesses a strong fatty odor but when diluted suggests violet leaves and orris. Traces only are to be used in jasmine, tuberose, lily of the valley, and violet.

Aldehyde-C_{12} (methylnonylacetic aldehyde)—This is the most important of the aldehyde series. When highly diluted it has the odor of the fresh peel of oranges and lemons and gives a freshness and originality to perfumes.

Anisic aldehyde (aubepine)—A colorless liquid, boiling at 91° C. (10 mm.); specific gravity 1.13 at 15° C. This liquid possesses the odor of hawthorne blossoms and is the basis for that odor. It is also used in the preparation of synthetic acacia, wallflower, new-mown hay, sweet pea, orchid, lotus, elder flower, etc. It dissolves in alcohol, oils, or glycerin and blends well with terpineol, linaloöl and terpinyl acetate.

Cinnamic aldehyde—A yellowish liquid, boiling at from 118° to 120° C. (10 mm.); crystallizing at −7° C.; specific gravity 1.06 at 15° C. It is the most important constituent of the oils of cinnamon. It is used to perfume soaps and hair washes, and is employed in various oriental type perfumes.

Benzaldehyde (see page 990).

Citral—This is an unsaturated aldehyde and occurs naturally in the oils of lemon, lime, verbena, lemon grass, etc. It is more soluble in water or dilute alcohol than oil of lemon and, when pure, is often used in place of *terpeneless oil of lemon*. In perfumery it imparts a fresh lemon odor to perfumes producing the so-called lemon soaps and creams.

Citronellal—A colorless liquid, boiling at from 72° to 73° C. (6 mm.); specific gravity 0.86 at 15° C. It occurs naturally in citronella oil from which it is extracted. The odor suggests citral. It is used in cheap soaps, but they must be neutral, or they will decompose it.

Heliotropine (piperonal)—White crystals, melting at from 36° to 37° C. and boiling at about 135° C. (10 mm.). This is one of the most important synthetic perfumery products, having the distinct odor of heliotrope and being an excellent modifier and fixative. It is used in perfuming soaps, sachets, powders and in the preparation of most synthetic perfume oils. Sometimes heliotropine is said to discolor. In reality, if properly used it does not discolor. Being an aldehyde, it is sensitive to alkali and certain metals, such as iron, and these must therefore be avoided.

Hydroxy-citronellal (laurine)—A thick, oily liquid, boiling at 116° C. (2.5 mm.) and having a specific gravity of 0.93 at 15° C. It has a sweet and powerful odor suggesting flowers such as lily of the valley, honeysuckle, cyclamen, linden blossoms, etc. It is possible to use it in many sweet flower perfumes and it also serves as a fixative. As much as 25 per cent may be used in lilac, from 10 to 40 per cent in lily, about 15 per cent in magnolia, etc. It is one of the most valuable developments of recent perfumery chemistry.

Phenylacetic aldehyde (jacinthe)—A colorless liquid, boiling at from 74° to 75° C. (6 mm.); specific gravity from 1.03 to 1.05 at 15° C. Its odor strongly resembles hyacinth and is valuable in the production of synthetic hyacinth, rose, narcissus, lilac, sweet pea, jonquil and other related odors. It should be kept in 50 per cent alcoholic solution as the pure aldehyde quickly polymerizes and becomes odorless. It is a fixative and increases the bouquet of perfumes. It should not be used in soaps unless they are perfectly neutral.

Phenylpropylic aldehyde (*hydrocinnamic aldehyde*)—The odor suggests hyacinth and must be used only in small amounts as it is very persistent. About 1 per cent may be used in lilac perfumes.

Salicylic aldehyde—This is an aromatic liquid, occurring naturally in several oils of the Fam. *Rosaceæ*. It is prepared synthetically and is the starting point in the making of coumarin. It is used in the preparation of some violet perfumes.

Vanillin—A white, crystalline product having the odor of vanilla (see page 977). It is used in many perfumes because of its sweet odor and excellent fixative qualities. As it turns brown with alkali or when in contact with metallic substances. It should be used carefully in white creams or soaps and it is unsuited for other soaps unless they are neutral.

KETONES

Acetophenone (*hypnone*)—A colorless liquid, crystallizing at low temperatures. It boils at about 79° C. and melts at 20° C. It occurs naturally in labdanum and the odor is flowery and is used in new-mown hay, crab-apple, lilac, syringa and other perfumes.

Carvone—A constituent of caraway oil, used in tooth pastes, mouth washes, etc.

Ionone (*irisone, iralol, ional, rhodione, atonone, etc.*) (a mixture of alpha and beta varieties)—This is the universally used violet odor. It is prepared through the condensation of citral with acetone in the presence of an alkali. The mixed ketones are used chiefly in the perfumery of soaps, 10 Gm. being sufficient for 100 kilos of soap.

Ionone-alpha (known under many names as *alefol, irisone-alpha*, etc.)—It is the most valuable product for preparing fine violet perfumes but must be skilfully blended with other substances such as orris concrete, and the oils of ylang-ylang, santol, bergamot, clarysage, cassie, etc., to develop "body".

Ionone-beta—This ketone is used about the same way as the other ionones but mostly in oriental bouquets to produce a very heavy odor.

Ionone-gamma—A third isomer of ionone having the characteristic odor resembling Russian leather and particularly valuable in oriental odors.

Methyl acetophenone—A colorless liquid, boiling at 223° C.; specific gravity 1.01 at 15° C. It possesses a fine flowery odor resembling mimosa and is largely used in perfuming soaps and in flavoring tobacco. It is also used as the basis for synthetic mimosa and as a modifier in synthetic cassie, hawthorne, lily, violet, heliotrope, etc.

ESTERS

Amyl acetate—A colorless liquid, boiling at about 139° C. It has a very fruity odor suggesting pears and gives sweetness to many perfumes, notably hyacinth. It is used as a solvent for pyroxylin.

Amyl benzoate—A colorless liquid having an odor suggesting ambergris. It is an excellent fixative.

Amyl butyrate—This liquid has a fruity odor and is sometimes used in synthetic jasmine.

Amyl salicylate (*trefoil, orchidea*)—A colorless liquid, boiling at from 151° to 152° C.; specific gravity 1.05 at 15° C. Its odor resembles some orchids and is the basis for clover perfumes. It is used in various cheap and powerful perfumes. It is used as a modifier in chypre, new-mown hay, carnation, etc. It is used in soaps.

Amyl valerate—The odor of this ester suggests apples and it is used as the basis for crab-apple perfume.

Benzylacetate—A colorless liquid, boiling at 216° C., specific gravity 1.06. It possesses an ethereal and fruity odor and is one of the principal constituents in the natural oils of jasmine, ylang-ylang, cassie, etc. It replaces natural jasmine in cheap perfumery and especially in soaps.

Benzyl benzoate—It has a slightly balsamic odor and is used chiefly as a solvent for musk and other non-alcohol soluble perfumes and also as a fixative. It may be used in soaps (see also page 837).

Bornyl acetate—The crystal product melts at 29° C. and boils at 98° C. (10 mm.). It has the odor of pine needles and is especially used to cover disagreeable odors in hospitals, theaters, etc. It is combined with other perfumes to make spray perfumes, toilet waters, bath crystals, etc.

Ethyl acetate (*acetic ether*)—A liquid having a pleasant and fruity odor, much used in fruit essences. It gives a refreshing odor to toilet waters, toilet vinegars, and other perfumes such as magnolia, cyclamen, ylang-ylang, but traces only must be used.

Ethyl benzoate—A colorless liquid, boiling at 213° C. The odor resembles methyl benzoate but is softer and more aromatic. It is used in artificial ylang-ylang, new-mown hay, niobe and peau d'Espagne.

Ethyl butyrate (*butyric ether, pineapple oil*)—The odor recalls that of rose and traces are sometimes used in synthetic rose. It is chiefly used to produce artificial pineapple essence.

Ethyl cinnamate—This ester boils at 271° C. and occurs naturally in storax. It has a balsamic and fruity odor, and is an excellent fixative for Cologne water and other toilet waters. It is also used in oriental perfumes, in fancy bouquets, and in soaps.

Ethyl formate—The odor and uses are very similar to those of ethyl acetate.

Ethyl laurinate—It has a pleasant but not a powerful odor, used as a fixative in tuberose and fancy perfumes.

Ethyl nonylate—A liquid having an odor suggesting roses. It is chiefly used in flavoring beverages.

Ethyl phenylacetate—The odor is distinctly that of honey, also suggesting rose and musk. It is used in synthetic rose, lily and sweet pea perfumes but chiefly to produce an artificial honey flavor. It is much used in perfuming tobacco.

Ethyl salicylate—A liquid having an odor much like methyl salicylate or wintergreen but finer. It is used in making synthetic cassie.

Ethyl valerate—It has a flowery and also a fruity odor and is chiefly used in fruit essences and fancy perfumes.

Geranyl acetate—A colorless liquid, boiling at from 128° to 129° C.; specific gravity 0.92 at 15° C. The commercial product contains about 92 per cent of the ester. It occurs naturally in the oils of lavender and spike and may be used in perfumes, soaps, and creams. It is used in preparing artificial tuberose, wallflower, neroli and gives freshness to the perfume.

Geranyl butyrate—Prepared only synthetically. It possesses a heavy and rose-like odor, also suggests apples. It is used for apple essence and in preparing perfumes like rose and geranium wherein it also serves as a fixative.

Geranyl formate—Its odor suggests roses and is a component of many synthetic rose and neroli perfumes.

Geranyl propionate—The odor is suggestive of roses and is used in some artificial rose oils and also in making bergamot oils. It has excellent fixative qualities.

Isobutyl salicylate—A colorless liquid, boiling at 260° C. It has a very sweet odor and is especially suited for use in perfumes of the clover type. Also used in such perfumes as orchid and cassie.

Isobutyl acetate—It has an odor suggesting hyacinth and roses and is especially used as a rose modifier, particularly to produce the Maréchal Niel type.

Isobutyl benzoate—A liquid having a pleasant odor suggesting lilies. It is a valuable fixative and is also used as a modifier in artificial oils of neroli, sweet pea, clover, acacia, etc.

Isobutyl phenylacetate—Its odor is sweet and suggestive of sweet briar rose. It is used to give a note of sweetness to flower perfumes, especially carnation, rose, tuberose, sweet pea, honey, etc.

Linalyl acetate—A colorless liquid, boiling at from 79° to 80° C.; specific gravity 0.91 at 15° C. Soluble in all proportions in alcohol. The commercial product contains from 90 to 92 per cent of the ester, the remainder being linaloöl. It occurs naturally in the oils of bergamot, jasmine, ylang-ylang, and is the principal substitute for oil of bergamot, especially in Cologne water and also in artificial lily of the valley, jasmine, lilac, linden blossoms, ylang-ylang, lavender, azurea, etc.

Linalyl benzoate—A liquid having a heavy odor; useful in perfumes of the oriental type.

Linalyl cinnamate—Much like linalyl benzoate.

Methyl anthranilate—This ester is crystalline, melting at about 24° C. It has an odor strongly resembling orange blossoms and is used as the basis for artificial neroli or to replace natural neroli oil.

Methyl benzoate (*niobe oil*)—A liquid having a strong, balsamic odor. It is combined with vertivert, oak moss or labdanum in the making of the base peau d'Espagne. It is much used in perfuming soaps, but only traces should be used in perfumes.

Methyl cinnamate—A liquid having a heavy, fruity odor suggesting strawberry. It is a valuable fixative for lilac, oriental bouquets, fancy compounds, bath salts, etc.

Methyl heptine carbonate—This is often called *"vert de violette, artificial"*. By itself the odor is offensive but used properly it produces the leafy odor often desired in violet perfumes.

Methyl anthranilate (*Di-methylanthranilate*)—A yellowish liquid crystallizing at 15° C. It boils at from 130° to 131° C. It is present in natural *petit-grain Mandarine oil* to the extent of 50 to 60 per cent, but differs from the natural oil in odor. It gives a distinct novelty to perfumes.

Methylphenylcarbinol acetate—This ester is sometimes sold as *gardeniol*, having an odor suggesting gardenias. It may be used in producing an artificial perfume sold under that name and to give a fresh odor to lilac and other floral odors.

Naphthol (*beta*) *ethyl ether* (*bromelia*)—The odor of this crystalline compound suggests orange blossoms but it is crude and very powerful. It is used only in soaps in very minute amounts.

Naphthol (*beta*) *methyl ether* (*nerolin, yara yara*)—This crystalline product possesses the distinct odor of neroli but is suited only for soap perfumery as it must be highly diluted.

Phenylethyl acetate—It has an odor suggestive of peaches or other fruits. It produces leafy effects in floral odors.

Phenylethyl butyrate—Its odor suggests roses and it is used in jasmine perfume, especially in creams.

Phenylethyl formate—Its odor suggests the white or eglantine rose and has been used in rose, lilac, lily, and orchid perfumes, but is not stable.

Phenylethyl propionate—The odor is very sweet, suggesting dried rose petals. It is used as a modifier in sweet perfumes.

Phenylmethyl butyrate—A liquid having a powerful fruity odor. Sometimes used in artificial rose, but it must be used sparingly.

Rhodinol acetate—A colorless liquid boiling between 110° and 120° C. (10 mm.). It is miscible in all proportions with alcohol. It has a distinct rose odor and is used in many artificial rose perfumes. It may be used in creams and in toilet soaps.

Rhodinol butyrate—A liquid having a rose odor; especially valuable in obtaining the moss rose effect and as a fixative.

Rhodinol formate—A colorless liquid having an odor suggesting wild roses. It is used in making artificial carnation or rose.

Terpinyl acetate—A colorless liquid, boiling between 90° and 94° C. (10 mm.); specific gravity 0.96 at 15° C. It is miscible with alcohol in all proportions. The commercial product contains about 92 per cent of ester. Its odor suggests bergamot and lavender and it is chiefly used in the perfumery of soaps as a cheap substitute for lavender or bergamot.

PHENOL ETHERS

Anethol—A white, crystalline product obtained from the oil of anise, star-anise, and fennel (see page 969). By oxidation it yields anisic aldehyde (aubepine) (see page 1213).

Carvacrol—A phenol obtained from the oils of thyme and origanum. It is used in soap perfumery.

Eugenol—(See page 974).

Isoeugenol—A thick, yellowish liquid crystallizing at low temperatures. It boils between 111° and 113° C. (10 mm.); specific gravity 1.09 at 15° C. Its odor is similar to eugenol but sweeter. It is used in the preparation of synthetic carnation perfumes. It also becomes a component in artificial lilac, ideal, jonquil, night scented stock, oriental soaps, etc. It is especially adapted for soap perfume.

Safrol—This phenol occurs naturally in sassafras oil and is the main constituent of synthetic sassafras oil. It is largely used as a perfume in cheap soaps.

MISCELLANEOUS SYNTHETIC PERFUMERY COMPOUNDS

Brom-styrol (hyacinthin)—This halogenated hydrocarbon is a yellowish liquid boiling between 219° and 221° C.; specific gravity 1.43 at 15° C. It has a powerful but crude odor suggesting hyacinth but is useful in soaps, especially those to be perfumed with rose, hyacinth, lilac, heliotrope, etc. It is alkali proof.

Coumarin—A white, crystalline lactone melting between 67° and 69° C. and boiling at about 154° C. It is the odorous substance occurring naturally in tonka beans, or many grasses and is the basis for the perfume known as new-mown hay. The commercial product is prepared synthetically. It is also used as soap perfume and is a valuable fixative.

Diphenylmethane—This hydrocarbon has an odor suggesting geraniums and is important as a soap perfume because it is alkali proof.

Diphenyl-oxide—This liquid has an intense odor of geranium and being very stable in soaps is much used in that industry.

Indol—A white, crystalline body melting at about 52° C. and boiling at 254° C. and soon darkening on exposure to light. It has a powerful and dis-

agreeable odor unless highly diluted when it becomes jasmine-like. It occurs naturally in the oils of jasmine and neroli, and body secretions.

Musk ambrette (100 per cent)—Yellowish crystals, melting at 85° C. Its solubilities are as follows: 20 Gm. in 1000 cc. of ethyl alcohol (95 per cent); 161 Gm. in 1000 cc. of benzyl alcohol; 290 Gm. in 1000 cc. of diethylphthalate; 450 Gm. in 1000 cc. of benzyl benzoate. This substance is largely used as a fixative to replace natural musk but differs distinctly in odor, having the agreeable character of ambrette seed. It is employed as a fixative, usually dissolved in benzyl benzoate, in such perfumes as acacia, carnation, lily, ylang-ylang, magnolia, mimosa, narcissus, jonquil, clover, violet, etc. It is a valuable fixative for soaps on account of its strength.

Musk ketone—Yellowish crystals, melting at about 135° C. Its solubilities are as follows: 15 Gm. in 1000 cc. of ethyl alcohol (95 per cent); 134 Gm. in 1000 cc. of benzyl alcohol; 155 Gm. in 1000 cc. of diethylphthalate; 205 Gm. in 1000 cc. of benzyl benzoate. This artificial musk most nearly resembles natural musk in its odor. It is therefore used when musk odor is desired and also as a fixative in many perfumes, soaps, and creams.

Musk xylol (musk xylene)—Yellowish crystals, melting at about 112° C. Its solubilities are as follows: 7 Gm. in 1000 cc. of ethyl alcohol (95 per cent); 85 Gm. in 1000 cc. of benzyl alcohol; 135 Gm. in 1000 cc. of ethyl phthalate; 280 Gm. in 1000 cc. of benzyl benzoate. The musk-like odor of musk xylol is not so powerful as the other synthetic musks, hence the others are more often used. It is, however, a valuable fixative.

Skatol—In concentration this nitrogenated product has a very disagreeable odor suggesting civet, but when well-diluted the odor is not unpleasant and it is used as a fixative in flower-like odors. It becomes red when long exposed to the air.

Fixatives—The proper fixing of a perfume is one of the most important problems before the perfumer. Most floral odors so lavishly expend themselves, actual physical particles being volatilized, that unless this process is retarded the finest perfume will prove unsatisfactory to the user because of the lack of lasting qualities. The earliest records of perfumery indicate that this was understood thousands of years ago and some of the fixative agents used today were employed by the Egyptians and Greeks as set forth in the writings of Theophrastus (370 B. C.).

Some fixatives do not of themselves possess pleasant odors and some are even disagreeable, as civet, castor, indol, and valerian. Others are pleasantly aromatic as benzoin, olibanum, musk, ambergris, vanillin, coumarin, heliotropine, etc., and still others have little or no odor, as benzyl benzoate and ethyl phthalate.

Fixatives from animal sources—Some of these products were used by the earliest perfumers but are largely being replaced today by vegetable or synthetic products of high boiling point.

Musk—This is the dried secretion from the preputial follicles of the male musk deer (*Moschus moschiferus*) found only in the Himalayan and Atlas mountain ranges. The most important variety is known as *Tonquin musk* which comes from Tibet. The musk pods consist of a round sack about one and a half inches in diameter, on the exterior side covered with coarse hair, arranged about the central orifice. *Grain musk* consists of the dried secretion, carefully removed from the pod, and is especially subject to adulteration with dried blood, or earth, and must be carefully tested (see the U. S. P. IX tests). For the finest perfumes of a floral type genuine musk is considered indispensable.

Substitutes in the form of artificial musk have been considered elsewhere (see page 1217).

Castor—This fixative consists of the dried preputial follicles and their secretions, obtained from the beaver (*Castor fiber*). The follicles are obtained from both the male and female beavers. The odor is strong and disagreeable.

Civet—This consists of a yellowish-white fatty mass obtained as a glandular secretion from the civet cat (*Viverra civetta*) which is domesticated and raised in Abyssinia and in the Indian archipelago for the secretion.

Ambergris—This valuable fixative is a secretion obtained only from the sperm whale and is usually found floating on the sea or on the sea shore. It varies greatly in color and odor and its value is correspondingly dependent upon the quality. Its odor is sweet and possesses marvellous fixative properties.

Fixatives from vegetable sources—These have also been used from the earliest times, the most ancient writers referring to members of this group which are all volatile oils, resins, gum resins, oleoresins or balsams. Most of these substances are also used in medicine and have been described elsewhere. The most important are *benzoin, galbanum, orris, labdanum, oak moss, myrrh, olibanum, opoponax, patchouli, balsam of Peru, santal oil, storax, tolu, vertivert,* and *vanilla.* They are sometimes used as tinctures, having been made by extraction with alcohol, but many of them today are available as concentrated oleoresins, having been extracted by volatile solvents.

Fixatives from synthetic chemicals—This group represents the development of the modern organic chemist and its representatives are some of the most valuable fixatives available today. The pleasant odors in some instances add merit to the fixative while in other cases the absence of all side odors is exactly what is required. The high boiling point of many of these products explains in part their efficiency as fixatives.

These products have been described individually and attention called to their specific uses (see page 1218). Among the most outstanding representatives are *coumarin, heliotropine, hydroxycitronellal, ionone, artificial musks, santalol, vanillin,* etc.

A comprehensive study of the application of various fixatives is given in a recent publication by W. A. Poucher, called *Perfumes and Cosmetics* and the reader is referred to this book for the details.

Dyes Suitable for Perfumes—Practically all colors used today in perfumes, soaps, or creams are of coal-tar origin. Such dyes may be purchased from the manufactureres in powder form and if water-soluble may be dissolved by boiling water. The solution should then be filtered to remove any undissolved particles. Other dyes are oil-soluble only and are used in fatty creams. Colors used in face powders are called "lakes" and are completely insoluble in water since a water-soluble dye would be objectionable.

For soaps or for alkaline solutions only such dyes must be used as are alkali-fast.

Dealers in perfumery supplies usually offer dyes suitable for every purpose, either in liquid or powder form.

The coloring matter in toilet water and other liquid perfumes must not be sufficient in quantity to produce a stain when used upon the handkerchief or clothing.

Many medicinal dyes can be used such as methylene blue for blue, scarlet red sulphonate for reds, acriflavine for yellow, proflavine for brown, and mixtures of the yellow and blue for green and of red and blue for lilac and violet shades. Scarlet red is soluble in oils, including petrolatum, and can therefore be used in creams.

From these few basic colors almost any desired shade or tint may be obtained through diluting or combining the colors.

No colors should be used which might be irritating or poisonous when applied to the skin, and for tooth powders or tooth washes only the certified food colors should be employed (see page 841).

THE STRUCTURE OF A PERFUME

The perfumery chemist finds it unsatisfactory to create a finished odor by using natural perfumes alone. He finds it equally undesirable to prepare an acceptable perfume by using only synthetic products. Therefore, both the natural and the synthetic products must be drawn upon and skilfully blended to produce the fine quality of perfumes of today.

The compounding of a perfume requires the consideration of a number of factors.

In creating a new odor, the perfumer must first determine the type of perfume desired. A large number of specialties are today available from dealers in perfumery supplies, giving, either alone or in combination, almost every variety of odor that could be ordinarily wanted. If it is preferable to build the odor from pure chemicals and volatile oils, it will be necessary to first produce an equivalent of the commercial specialties and it should be borne in mind that all the successes in modern perfumery are based upon specialties, which have required years of research for their development. This basic product, which determines the character of the perfume, is known as the "*body*".

The next step is to select from the different fixatives those which are in harmony with the determined type of odor. Practically all fixatives have an odor, for without odor they would dilute and have a tendency to "flatten" the perfume. Suppose an odor resembling "chypre" is desired. The base "chypre" will probably be obtained from a reliable perfume house and a drop of this will be placed on a blotter. After smelling it, the blotter will be set aside for twenty-four hours and then again smelled. If it is not sweet and lasting enough some coumarin, vanillin, musk ambrette, opoponax, or ambre synthetic, will be used in balanced proportion, to obtain the desired effect.

When the fixative has been adjusted it may be found that the perfume does not contain enough *aromatic*. This may be corrected by using the proper proportion of orris concrete, oak moss oleoresin, or such products as the fluid preparations of tolu, galbanum, opoponax, olibanum, etc.

When the perfume is lasting and sweet enough, it is time to add the "*top note*". This is obtained with absolute flower oils, from the concentrated washings of the pomades of jasmine, rose, tuberose, etc., or from such volatile oils as neroli and ylang-ylang.

Finally, to give *freshness* to the perfume, the perfumer will use such volatile oils as bergamot, orange, cedrat, lime, etc.

The natural fixatives, such as ambergris, Tonquin musk, and civet do not sensibly modify the odor, and can be added in small proportion when the perfume is finished. No exact proportion can be predetermined as the amount depends upon the type of the perfume and the limit of cost.

To recapitulate, the scientific preparation of a perfume requires:

1. The selection of the "body" or base, to give the general character.
2. Fixation.
3. Finishing (incorporating the top odor, to furnish the bouquet or "fleuri" to the finished perfume).
4. Dilution of the perfume with the proper solvent for the proper concentration.

Floral odors—On the following pages a few of the more important floral odors used in modern perfumery will be discussed and typical formulas given. These formulas are only suggestive but give a fair conception of the make-up of commercial products. They have been largely supplied through the kindness of Philip E. Chaleyer, director of the perfumery laboratory of the Burton T. Bush Company and it will be gratifying for many to know that through an arrangement between Mr. Burton T. Bush, and the French firm of L. Givaudan and Company, a large factory has been established at Delawanna, N. J., where aromatic chemicals and many other basic perfumery materials are manufactured on a large scale. The assistance of Mr. Chaleyer and the use of the physical factors given in the section on aromatic chemicals have been with the approval of Mr. Bush. The factors given constitute the standards of the "Givaudan-Delawanna" products by whom they are rigidly maintained. These do not always indicate one hundred per cent purity, as this is often impracticable, but it is to the credit of the Givaudan organization that it has been willing to establish physical factors and definite degrees of purity for these products heretofore unstandardized. This insures a uniformity of product which establishes the perfumery industry upon a more satisfactory basis than has been heretofore possible.

Carnation—The natural product is very seldom used as it is expensive and unsatisfactory. The synthetic carnation is known as *œillet, dianthus, dianthine,* etc. The main constituents of this perfume are rose, isoeugenol, linaloöl, ionone, neroli, vanillin, heliotropine, and benzyl acetate.

A typical formula made from basic ingredients would be as follows:

CARNATION

Natural oil of rose	10
Isoeugenol	15
50 per cent phenylacetaldehyde	10
Linaloöl	10
Ionone (pure)	10
Benzyl acetate	10
Neroline	5
Heliotropine	10
Vanillin	10
Benzyl acetate	10
To make	100 parts

Cassie—(Oil of Cassie must not be confounded with Oil of Cassia or Cinnamon Oil).

This oil from *Acacia farnesiana* (Fam. *Leguminosæ*), a shrub cultivated in Southern France and in Syria, possesses an odor resembling the violet. It is obtainable, for perfumery, chiefly in the form of cassie absolute, cassie liquid absolute, cassie concrete, and cassie pomade. It is mostly used for making synthetic violet, and also is a constituent in oriental bouquet. The chemical constituents of cassie are mainly geraniol, linaloöl, farnesol, benzyl alcohol, methyl salicylate, decylic aldehyde, cuminic aldehyde, 10 per cent of anisic aldehyde, and also a ketone of a violet-like odor.

Cyclamen—The cyclamen flowers (*C. persicum*) grow mostly in certain mountainous districts of France (more especially in Savoy), and the fresh flower loses most of its odor after having been picked. When cultivated it has no odor, but the wild flower has an extremely sweet odor as fine as that of violet but with a distinct character of its own. In preparing an artificial oil the following are chiefly used; ionone, linaloöl, terpineol, hydroxy-citronellol, and

phenylacetic aldehyde. By means of a new chemical body recently discovered, a more true imitation of the odor of this flower has been produced.

Heliotrope—Heliotrope odor is based upon heliotropine, which is the main odor, but to it are added terpineol, vanillin, eugenol, benzyl acetate, ylang-ylang and small quantities of the oil of tuberose and jasmine.

A typical formula is as follows:

HELIOTROPE

Terpineol	20
Heliotropine	20
Vanillin	10
Coumarin	10
Benzyl acetate	10
Ylang-ylang (Bourdon)	5
Rose, absolute or synthetic French rose	5
Tuberose absolute (liquid)	5
Jasmine (synthetic)	15
To make	100 parts

Good bases for making fine heliotrope extract are sold as *heliotrope liquid, heliotrope concrete, heliotrope blanc* (not discoloring for creams), *heliotrope amorphous* (small crystals to be used for powder and rouge).

Hyacinth (*Jacinthe*)—It is nearly impossible to obtain a natural odor product from the hyacinth flowers, so that a synthetic product is used. The main constituent of synthetic hyacinth is phenylacetaldehyde. The main objection to this product is that it polymerizes quickly by action of air and light and must be used in creams only in minute quantity because it has an irritating action on the skin. To obviate this difficulty a 50 per cent mixture of phenylacetaldehyde with benzyl benzoate, benzyl alcohol or cinnamic alcohol is usually offered the trade. The chief constituents of a hyacinth formula are: rose absolute, heliotropine, cinnamic alcohol, phenylacetic aldehyde, phenylethyl alcohol, terpineol, geraniol, linaloöl and oil of bergamot.

A typical formula is as follows:

HYACINTH

Rose (synthetic, French)	10
Heliotropine	10
Cinnamic alcohol	20
Bergamot oil	10
Phenylacetaldehyde (50 per cent)	25
Jasmine (synthetic)	10
Terpineol	15
To make	100 parts

For a cheaper hyacinth, used largely in soap perfume brom-styrol is generally used to obtain the hyacinth effect. This odor is very stable.

Jasmine—Natural Jasmine is made mostly by the volatile solvent method and is available as absolute or concrete. A small amount is made into pomade.

Jasmine is the most important of all perfumery products since it enters almost every floral odor. An analysis shows the following more important constituents: 65 parts of benzyl acetate, 7.5 parts of linalyl acetate, 6 parts of benzyl alcohol; 15.5 parts of linaloöl; 2.5 parts of indol; 3 parts of jasmine (a ketone), and 0.5 parts of methyl anthranilate.

An artificial jasmine oil may be prepared as follows:

JASMINE

Benzyl acetate	30
Linalyl acetate	5
Linaloöl	10
Hydroxy-citronellol	10
Oil of Ylang-ylang (Bourbon)	5
Jasmine absolute	5 to 10
Aldehyde C_{10}	2
Phenylethyl alcohol	10
Rhodinol	10
Heliotropine	10
Benzyl alcohol, sufficient,	
To make	128 parts

Lilac—There is no natural oil of lilac or other natural product obtainable directly from the lilac flowers for the use of the perfumer. Fortunately this very popular odor has been very satisfactorily reproduced synthetically.

The alcohol terpineol possesses a lilac-like odor and is extensively used for creams and soaps where a cheap perfume is demanded but the better artificial lilac odors are prepared by blending other constituents. A typical formula is as follows:

LILAC

Heliotropine	10
Anisic aldehyde (aubepine)	5
Phenylethyl alcohol	20
Cinnamic alcohol	10
Phenylacetaldehyde (50 per cent)	10
Phenylpropylaldehyde	2
Rhodinol	5
Jasmine absolute	5
Benzyl acetate	10
Hydroxy-citronellol	10
Linaloöl	10
Terpineol, sufficient,	
To make	100 parts

Lily of the Valley (*muguet*)—Practically no floral oil is extracted directly from the flowers, a synthetic product being almost universally used for this odor. The following typical formula well illustrates the usual combination.

LILY OF THE VALLEY

Cinnamic acetate	5
Hydroxy-citronellol	15
Phenylethyl alcohol	10
Linaloöl	10
Benzyl acetate	15
Ionone	10
Rhodinol	10
Rose absolute	5
Jasmine absolute	5
Terpineol, sufficient,	
To make	100 parts

Orange Flowers—This delightful odor is a dominant factor in the making of Eau de Cologne. Two classes of products are offered in the trade: 1st, an oil made by steam distillation of the flowers. 2nd, a product extracted by the volatile solvent method called, "orange flower absolute, concrete, or liquid". Oil of petit-grain, distilled from the leaves and twigs of the orange tree, is also

used for making synthetic neroli. A by-product from the steam distillation of the flowers is orange flower water, used in pharmacy. Oil of neroli is the product generally used for the making of Eau de Cologne. Poucher gives the following formula to use to reproduce the absolute flower oil of Fleur d'Orange:

ORANGE FLOWERS

Nerol or geraniol, pure	35
Linaloöl	10
Methyl anthranilate	10
Indol	0.5
Methyl naphthyl ketone	10
Aldehyde C_9	0.5
Geranyl formate	2
Lily of the valley (synthetic)	6
Jasmine (synthetic)	3
Rose (synthetic)	3
Linalyl acetate	10
Benzoin resin	10
To make	100 parts

Rose—A description of this odor has already been given (see page 1220), and typical formulas are as follows:

BULGARIAN ROSE (Oriental)

Natural oil of rose (Bulgarian)	20
Geraniol	20
Citronellol	10
Phenylethyl alcohol	10
Phenylacetaldehyde (50 per cent)	5
Rhodinol, sufficient,	
To make	100 parts

FRENCH ROSE

Rose, absolute	20
Phenylethyl alcohol	10
Citronellol	15
Phenylpropyl alcohol	10
Isoeugenol	5
Rhodinol	14
Aldehyde C_8 (10 per cent)	1
Geraniol, sufficient,	
To make	100 parts

A more elaborate formula known to give much satisfaction is as follows:

WHITE ROSE EXTRACT

Rhodinol	14 cc.
Citronellol	14 cc.
Geraniol	42 cc.
Phenylacetic aldehyde	3 cc.
Phenylethyl alcohol	15.75 cc.
Decyl aldehyde (10 per cent in alcohol)	2 cc.
Eugenol	0.25 cc.
Cinnamic alcohol	2 cc.
Ionone	5 cc.
Linaloöl (from bois de rose)	6.25 cc.
Rose absolute	20.25 Gm
Oil of rose (Bulgarian)	3.50 cc.

Oil of patchouli	3 cc.
Oil of geranium (African)	10 cc.
Oil of bergamot	10 cc.
Vanillin	5 cc.
Oil of ylang-ylang (Manila)	2 cc.
Phenylethyl acetate	2 cc.
Methyl anthranilate	5 cc.
Oleoresin of oak moss	3 cc.
Musk ambrette (20 per cent solution in benzyl benzoate)	50 cc.
Tincture of Siam benzoin (25 per cent in alcohol)	129 cc.

Mix and age before filtering.

Violet—Natural violets are seldom used because of their high cost, but violet absolute and violet concrete are obtainable and these are made exclusively by the use of a volatile solvent. A product extracted from the leaves of the violet plant is also used to obtain a violet odor. Ionone, however, is mainly depended upon in perfumery for a violet odor but this must be skilfully blended with the extract from violet leaves and other modifiers such as methylheptine carbonate, orris absolute or concrete, cassie absolute or concrete, heliotropine, etc. The following is a typical formula:

VIOLET

Ionone (alpha)	50
Violet leaves, absolute	2
Cassie, absolute	5
Orris, liquid, absolute	5
Methylheptine carbonate	3
Heliotropine	15
Jasmine, synthetic, sufficient,	
To make	100 parts

Other Floral Odors—Other floral odors are of less importance than those already referred to but many have been synthetically produced and typical formulas may be found in the more extensive treatises on this subject, such as *Perfumes and Cosmetics* by W. A. Poucher. They include such odors as *acacia blossoms*, *gardenia*, *hawthorne* (*May blossoms* or *cratægus*), *honeysuckle*, *jonquil*, *lavender flowers*, *magnolia*, *mimosa*, *mignonette* or *reseda*, *narcissus*, *new-mown hay* (the basic odor of this perfume is coumarin which exists naturally in many grasses and other plants), *orchids*, *palmarosa*, *trèfle* (*clover*), *tuberose*, *wallflower*, *ylang-ylang* (the volatile oil).

Approximate Solubility of a Few Aromatic Chemicals in Various Strengths of Alcohol*

One part of a product is completely dissolved in X parts (smallest quantity necessary) of alcohol of X per cent.

		Alcohol by volume
Acetate, Benzyl	soluble in 1.5	parts of 70 per cent
Acetate, Bornyl	soluble in 2.5–3.5	parts of 70 per cent
Acetate, Geranyl	soluble in 7–8.5	parts of 70 per cent
Acetate, Linalyl	soluble in 3–5	parts of 70 per cent
Acetate, Terpinyl	soluble in 4.5	parts of 70 per cent
Alcohol, Benzylic	soluble in 1	part of 50 per cent
Alcohol, Cinnamic	soluble in 3.5–4.5	parts of 50 per cent
Alcohol, Phenylethylic	soluble in 2	parts of 50 per cent
Alcohol, Phenylpropylic	soluble in 3	parts of 50 per cent
Aldehyde, Cinnamic	soluble in 1.5–2.5	parts of 70 per cent
Aubepine	soluble in 6–6.5	parts of 50 per cent
Benzaldehyde	soluble in 1–1.5	parts of 70 per cent
Benzoate, Benzyl	soluble in 7.5	parts of 80 per cent
Benzoate, Ethyl	soluble in 6–7	parts of 60 per cent
Benzoate, Methyl	soluble in 3.5	parts of 60 per cent
Cinnamate, Ethyl	soluble in 4–6	parts of 70 per cent
Cinnamate, Methyl	soluble in 1.5	parts of 70 per cent
Citral	soluble in 7	parts of 60 per cent
Citronellal	soluble in 5	parts of 70 per cent
Citronellol	soluble in 4	parts of 60 per cent
Eugenol	soluble in 4.5–5	parts of 50 per cent
Geraniol, Pure	soluble in 2.5–3.5	parts of 60 per cent
Hydroxy-Citronellol	soluble in 6.5–7	parts of 30 per cent
Irisone, Pure	soluble in 2.5–3	parts of 70 per cent
Isoeugenol	soluble in 4.5–5	parts of 50 per cent
Jacinthe absolute	soluble in 2.5	parts of 70 per cent
Linaloöl	soluble in 4–5.5	parts of 60 per cent
Methyleugenol	soluble in 3.5	parts of 60 per cent
Salicylate, Amyl	soluble in 2.5	parts of 90 per cent
Salicylate, Ethyl	soluble in 3	parts of 80 per cent
Salicylate, Methyl	soluble in 4.5–6	parts of 70 per cent
Terpineol	soluble in 3–5	parts of 60 per cent

*Supplied by the Burton T. Bush Company.

CHAPTER LXXVII

MANUFACTURED PERFUME PRODUCTS

IN SUBMITTING formulas no attempt has been made to exhaustively cover this field, as manufacturers have access to other books which contain a large selection of formulas. The object has been to supply a few formulas for such preparations as are more within the scope of manufacture by the retail pharmacist and especially such as he would be able to sell under his own label.

The attention of the prospective perfumer or of those who desire more information in this field is called to the list of books at the end of this chapter.

Concentrated Perfume Extracts

These consist of strongly alcoholic solutions, containing at least four fluid-ounces of a concentrated perfume oil in each gallon.[1] Some floral odors are always popular such as rose, violet, heliotrope, lilac, lily of the valley, and others, but the tendency is to offer bouquets and blends under fancy names such as *corylopsis, chypre, ideal, l'origan,* etc.

Illustrative formulas for concentrated perfume oils will be found under *Floral odors* (page 1220) and many other formulas are available from modern

---

[1] **Alcohol for Perfumery**—Specially denatured alcohols are the only forms of alcohol permitted to be used, in the production of a perfumery product. Authority to use these alcohols must be obtained by application to the office of the Prohibition Administrator of your District, the request being made upon the special form provided and accompanied by the proposed formulas. Samples of the finished product must also be furnished.

For rendering toilet preparations unfit for beverage purposes.

The following alternative substances are used in *bay rum, hair tonic, and toilet waters.*

Tartar emetic, ¼ grain per fl. oz.,
or quinine, salt or alkaloid, 2 grains per fl. oz.,
or cinchonidine, salt or alkaloid, 2 grains per fl. oz.,
or salicylic acid, 5 grains per fl. oz.,
or resorcinol, 5 grains per fl. oz.,
or sodium salicylate, 5 grains per fl. oz.

It is understood that these modifying agents are not sufficient of themselves to render the preparations unfit for beverage purposes but that they must contain other medicating ingredients and each formula must be judged upon its own merits.

Formula 38—For use in *mouth washes* and *dentifrices*
10 lbs. oil of wintergreen (or methyl salicylate) or either of the following: 10 lbs. of oil of cassia, 10 lbs. oil of clove, 10 lbs. oil of peppermint in addition to 5 gal. of water containing 60 oz. of zinc chloride in 100 gal. of pure ethyl alcohol.

Formula 38-*A*—For use in *liquid dentifrices*
5 oz. menthol (crystals), 9 oz. emetine hydrochloride, and 16 lbs. benzoic acid, in 100 gal. of pure ethyl alcohol.

Formula 39—For use in manufacturing *barbers' supplies*
9 lbs. (av.) sodium salicylate (or, as an alternative, 9 lbs. of salicylic acid may be used), 1¼ gal. fluidextract of quassia, and 1 gal. acetone or isopropyl alcohol in 100 gal. of pure ethyl alcohol.

Formula 39-*A*—For use in *barbers' supplies*
60 oz. (av.) of any of the following alkaloids or salts: quinine, quinine bisulphate, quinine hydrochloride, cinchonidine, or cinchonidine sulphate, and 1 gal. acetone or isopropyl alcohol in 100 gal. of pure ethyl alcohol.

Formula 39-*B*—For *perfumes, barbers' supplies, toilet waters,* and *lotions*
2½ gal. diethylphthalate in 100 gal. of pure ethyl alcohol.

Formula 39-*C*—For *high-grade perfumes* and *toilet waters,* containing not less than 2 per cent by weight of essential oils, or their equivalent in perfume materials. (Granted only under special conditions). 1 gal. diethylphthalate in 100 gal. of pure ethyl alcohol.

Formula 39-*B*—For *bay rum* and *lotions* for external use
50 oz. (av.) quinine sulphate, or 200 oz. (av.) sodium salicylate in 100 gal. of pure ethyl alcohol.

Formula 40—Used for manufacturing perfumes and high grade toilet preparations
3 oz. (av.) brucine sulphate, and ½ gal. of acetone in 100 gal. of pure ethyl alcohol.

books on perfumery. Perfume oils may also be purchased from many sources, ready for dilution with alcohol or for use in many other products.

The quantity of oil to be added to each gallon, mentioned above, is the minimum, but many of the more expensive perfumes are much more concentrated and such perfumes must be used in proportionally smaller amounts. After dilution in alcohol the mixture should be allowed to age or blend, in glass containers, in a cool and dark place, for as long a time as possible.

Most extracts are of the natural color, being yellowish or amber, and artificial colors are rarely employed.

TOILET WATERS

These preparations are simply weaker "extracts". They should contain at least one fluidounce of the perfume oil to the gallon. Their alcoholic strength is also slightly less than extracts although the term "water" is anomalous since they are strongly alcoholic, usually from 60 to 75 per cent, by volume.

When the perfume oil has been added to the alcohol in the proportion suggested, distilled water may then be added, in small amounts, at the first indication of cloudiness, that the alcoholic strength may be of the minimum to carry the added oil.

The toilet water is then colored by the use of an aniline dye, in solution, but the amount added must be carefully adjusted so that the toilet water will not stain the skin or clothing. Usually the color is only suggestive, a lilac tint for lilac water, a green or violet for violet water, pink for rose, etc.

A small amount of talc is then added and the water set aside in glass, in a cool place to age or blend. It must finally be filtered and should be brilliantly clear when bottled and used.

COLOGNE WATER

Cologne Water for several hundred years has justly occupied an important place among perfumes. It had its origin in the city of Cologne, Germany, and has been prepared by the same firms for a long period. It is essentially an alcoholic solution of citrus oils, among which oil of neroli is the most important.

A special form of cologne water in which menthol is dissolved has been largely sold under the name of *Headache Cologne*. These products are delightfully refreshing and possess genuine therapeutic value. The plain cologne waters are especially acceptable when used in a sick-room. The headache cologne when applied to the forehead is both refreshing and stimulating. Similar preparations have been made under the name of Lavender Water, Florida Water, etc. Typical formulas are given below and many other formulas will be found in books on perfumery.

SPIRITUS ODORATUS. N. F. V. **Perfumed Spirit (Cologne Water)**

(See page 313)

Cologne Water (Scoville)

	Metric	Alternative
Oil of Bergamot	**12 cc.**	3 fl. dr.
Oil of Lemon	**6 cc.**	1½ fl. dr.
Oil of Neroli	**4 cc.**	1 fl. dr.
Oil of Orange	**2 cc.**	30 min.
Oil of Rosemary	**2 cc.**	30 min.
Tincture of Siam Benzoin	**8 cc.**	2 fl. dr.
Orange Flower Water	**100 cc.**	3 fl. oz.
Alcohol, sufficient, to make	**1000 cc.**	2 pints

Dissolve the oils in the alcohol, add the tincture and finally the water. Allow to blend and filter.

Cologne Water (Blackwood)	Metric	Alternative
Oil of Lavender Flowers	2 cc.	1 fl. dr.
Oil of Lemon	8 cc.	4 fl. dr.
Oil of Neroli	1 cc.	30 min.
Alcohol, sufficient, to make	1000 cc.	4 pints

Headache Cologne

Add to any good cologne water from two to three drachms (120 to 180 grains) of menthol for each pint. Ten grains or more of camphor is sometimes added.

Florida Water

Oil of neroli	5 cc.
Oil of lavender flowers	5 cc.
Oil of bergamot	30 cc.
Oil of clove	2 cc.
Oil of cinnamon	3 cc.
Oil of rose	5 cc.
Orange flower water	100 cc.
Alcohol, sufficient, to make	1000 cc.

Lavender Water	Metric	Alternative
Oil of Lavender Flowers	25 cc.	6 fl. oz.
Rose water	500 cc.	1 pint
Alcohol, sufficient, to make	2000 cc.	4 pints

SACHETS

In modern perfumery there is a limited application for natural materials. A class of products known as "sachets" are still prepared largely from natural odorous substances. These had their origin, doubtless, through the instinctive practice of gathering and drying such flowers as the rose, lavender, orange flowers, and similar blossoms.

Among the natural perfume products entering sachets are found ambrette seed (musk seed), angelica seed, Canada snakeroot, cardamom, lavender flowers, oak moss, orange flowers, orris, patchouli leaves, red rose petals, sandalwood, tonka, vanilla, and vertivert root.

The perfume known as "Frangipanni", already referred to, is still found in modern books. A typical formula is given on page 1230.

A general combination of flowers is known under the title "potpourri". This is intended to be typical of the gathered flowers from the garden and it possesses a delightfully refreshing aroma. See formulas, page 1230.

Such odors as lavender and rose can be readily procured by using the flowers, but others, equally popular, such as violet, lilac, and heliotrope can only be simulated. One suggestion has been the artificial coloring of granulated orris and the perfuming of this with compound oils. Formulas of this kind are also presented.

A fixative is an important part of the sachet, otherwise the odor is rapidly dissipated. Orris root offers a valuable constituent to all sachet because of its sweet odor and also because of its fixative qualities. Such substances as powdered Siam benzoin or the added tincture of Siam benzoin, also sandalwood, and even musk in small amounts, or tincture of ambergris or civet may be added to the formula. Other fixatives also find application. See section on *Fixatives,* page 1218.

Potpourri (a)	Parts by weight
Lavender flowers	1750
Orris root, powdered	1750
Rose petals	1750
Clove buds, powdered	440
Cinnamon bark, powdered	440
Benzoin (Siam)	440
Pimento	440
Sodium chloride	880
Vanilla	330
Musk (or equivalent in 10 per cent solution of artificial musk)	100
Oil of bergamot	30
Oil of lemon	30
Oil of lavender flowers	15
Oil of sandalwood	15
Oil of rose geranium	15
Oil of rose	2
Tincture of ambergris	30

Mix the drugs, which should be in coarse particles, and then drop the oils and tincture on the drugs and mix thoroughly. Keep the product in a tightly-closed container.

Potpourri (b)	Parts by weight
Lavender flowers	3500
Rose petals	1750
Vanilla	60
Clove buds, powdered	60
Storax resin, powdered	60
Benzoin (Siam), powdered	60
Ambergris, powdered	20
Oil of rose	20

Prepare as directed for No. 1.

Frangipanni Sachet	Parts by weight
Orris, coarsely ground	3840
Rose petals	3840
Vanilla (or vanillin, $\frac{1}{16}$ as much)	240
Powdered benzoin (Siam)	240
Oil of sandalwood	120
Oil of neroli	60
Oil of lavender flowers	60
Oil of bergamot	60
Oil of cinnamon	24
Oil of pimento	40
Oil of rose	32

Carnation Sachet	Parts by weight
Orris, coarsely ground	3500
Lavender flowers	1750
Patchouli leaves	880
Clove buds, powdered	440
Tonka beans, powdered	440
Pimento, powdered	220
Musk	8
Oil of rose	40
Oil of lavender flowers	40
Oil of neroli	48
Oil of sandalwood	80

Heliotrope Sachet	Parts by weight
Tonka, coarsely ground	3500
Orris, coarsely ground	3500
Rose petals	3500
Powdered benzoin (Siam)	550
Vanilla	60
Heliotropin	180
Oil of rose geranium	20

Lavender Sachet	Parts by weight
Lavender flowers	3500
Powdered benzoin (Siam)	440
Oil of bergamot	30
Oil of lavender flowers	50

Rose Sachet (a)	Parts by weight
Rose petals	440
Oil of rose	2
Oil of rose geranium	2
Tincture of musk	1
Tincture of civet	1

Rose Sachet (b)	Parts by weight
Rose petals	1750
Orris root	1750
Sandalwood	150
Patchouli leaves	75
Tincture of civet	20
Oil of rose geranium	3
Oil of rose	2

Violet Sachet (a)	Parts by weight
Orris root, coarsely ground	528
Oil of bergamot	2
Oil of bitter almond	2
Oil of rose	2
Tincture of musk	30

Violet Sachet (b)	Parts by weight
Orris root, coarsely ground	1320
Powdered benzoin (Siam)	440
Spirit of bitter almond	2
10 per cent solution of ionone	15

Violet Sachet (c)	Parts by weight
Dark violet orris[1]	100
Powdered benzoin (Siam) (add 1 part in 60)	

Mix lightly and add violet oil, 1 part in 300, more or less.

[1] If ground or "granulated" orris is colored appropriately it increases the attractiveness of the sachet. To accomplish this an aqueous solution of the aniline dye is prepared, usually 1 in 1000, although a lighter or darker shade may be wanted when more or less of the dye may be taken. 100 cc. of this solution is added to each 200 Gm. of the coarsely ground orris, the whole mixed thoroughly and then dried in warm air. In this way orris may be colored to resemble ground violets, or rose petals, or lilac flowers, etc., and small quantities of green may be added to suggest stems.

Ylang-ylang Sachet	Parts by weight
Orange peel	2640
Orris, coarsely ground	2200
Rose petals	2200
Coumarin	1
Vanillin	2
Tincture of civet	10
Tincture of musk	5
Oil of ylang-ylang	15
Oil of rose	10
Oil of bergamot	5
Oil of rose geranium	300

Lilac Sachet	Parts by weight
Lilac colored orris (see footnote page 1231)	100
Powdered benzoin (Siam) (1 part in 60)	

Mix lightly and add lilac oil, 1 part in 40, more or less.

SMELLING SALTS

Dry Type—Ammonia in some form is the basis for all smelling salts and they are usually perfumed with lavender. When glass stoppers are used for smelling salts bottles, the stoppers should be greased with petrolatum to prevent sticking. Small fancy bottles containing smelling salts are frequently carried by women in their purses, to be used for the stimulating or refreshing effect of the salts. These are called *vinaigrettes* and are usually filled with a mixture made by triturating together equal parts (say one drachm each) of granular ammonium chloride and dry potassium carbonate, and adding a little oil of lavender flowers (two drops to the above quantity).

The attractiveness of these salts is increased if they are colored with alkali-fast aniline dyes. They may be colored green, pink, red, yellow, lavender, etc.

Liquid Type—Fill two ounce, wide-mouthed, glass-stoppered, green glass bottles, made specially for smelling salts, with small cubes (¼ inch size) of translucent ammonium carbonate (sometimes large crystal potassium sulphate is used) and pour over them the following liquid:

Oil of lemon	1 fl. dr.
Oil of lavender flowers	30 min.
Oil of clove	10 drops
Stronger ammonia water	1 fl. dr.
Alcohol	3 fl. oz.

Color this liquid if desirable, preferably with alkali-fast aniline green.

Solidified Smelling Salts—Dissolve 1.35 Gm. of sodium hydroxide in 40 cc. of 95 per cent alcohol in a flask, warm the solution on a water bath and then add 2 cc. of stronger ammonia water and 1 cc. of oil of lavender.

Add sufficient alkali-fast aniline dye solution to suitably color and then quickly introduce 8.5 Gm. of stearic acid previously dissolved in 50 cc. of hot, 95 per cent alcohol.

Rotate the mixture in the flask on a water bath until a clear solution results and pour this at once into suitable bottles, the bottles having been warmed. In pouring, use a long-stemmed funnel to avoid touching the sides of the bottles during filling. Stopper at once, greasing the stoppers.

BATH SALTS

The basis for bath salts is large crystal sea salt (sodium chloride). To this may advantageously be added varying amounts of sodium borate, in large crystals, for the softening of water.

Coloring—A suitable alcoholic solution of the color desired is either sprayed on the crystals or they are dipped in the solution, drained and dried. Suitable dyes are:

Auramine for yellow	Methyl violet for purple
Tartrazine for lemon yellow	Safranines for pink
Acridine orange for orange	Methylene blue for blues
Phenylene brown for terra-cotta	Basic green for emerald

Perfuming—Having colored and dried the crystals they may then be perfumed by spraying on the appropriate perfume oil. This should contain ample resinous material, such as from 10 to 25 per cent of the oleoresins of benzoin, olibanum, etc. Readily oxidizable oils or those decomposed by alkali are not suitable. Terpeneless oils only should be used if perfumes of that type are desired.

FACE POWDERS

A satisfactory face powder should possess the following qualities:

Freedom from all harmful ingredients such as lead or bismuth salts.
Adhesion to the skin.
Absorbent qualities.
Uniform and extreme fineness.
Opacity or covering properties.
Suitable color, evenly distributed and not water-soluble.
Uniform mixing of all ingredients.

Among the ingredients used in face powders are the following:

Precipitated chalk—Absorbent and adhesive.
Talcum—Use the "air-floated" variety, pure white and fluffy.
White clays—Adhesive
Zinc oxide—Mild therapeutic action, having a tendency to overcome roughness of the skin. It has great opacity.
Light magnesium carbonate—Gives lightness to powder.
Zinc stearate—Very adhesive. Adds smoothness to the finished powder.
Magnesium stearate—Especially valuable as an adhesive.
Starch—(rice and corn)—Use only powder of the greatest fineness. Use small quantities as it has a tendency to clog the pores of the skin during excessive perspiration.
Orris—As a fixative.

To Color Chalk and Talc for Face Powders and Tooth Powders—*For Flesh Tint*—Use aniline lakes which are absolutely insoluble in water. A water soluble dye would run and stain from perspiration or tears. Carmine is not satisfactory; Venetian red is sometimes used.

A suitable dry, red dye	1 Gm.
Alcohol	250 cc.

Mix them in a bottle, allow to stand for twenty-four hours, filter, and add alcohol to make 1000 cc.

Mix 8 cc. of this solution with 100 Gm. of precipitated chalk or talc, adding only a small quantity of the powder at first, and triturating; gradually add the remainder of the powder, and sift the product several times through a No. 30 sieve. Then dry on paper.

Mix this colored talc with uncolored face powder in the proportion of 1 to 10 or more if desired.

The following mixture is also suitable for "flesh tint".

Flesh 5173[1]	4 parts
Pink 5172 Z[1]	1⅛ parts

Mix and dissolve 40 grains of the mixture in 4 fl. oz. of water and add this amount to each pound of powder.

[1] From National Aniline, Dye and Chemical Company.

Brunette—Thoroughly triturate 1 part of burnt sienna, or of Spanish brown, or a mixture of these, to give the desired tint, with 9 parts of precipitated chalk. Sift the mixture several times through a No. 100 sieve.

The following mixture may also be used for brunette:

Brown "R"[2]	3 parts
Brunette[2]	1 part

Mix and dissolve 40 grains of the above mixtures in 4 fl. oz. of water and add to each pound of chalk.

Use this colored chalk to replace white chalk in formulas, as necessary to produce the desired shade.

High Brown—Add more of the same color used for brunette. This is for the use of negroes.

Other Shades—Care must be taken to select only harmless colors such as yellow ochre, Armenian bole, and for *blue*, which is sometimes applied around the eyes, use ultramarine or cobalt blue. For other shades such as orange, mauve, mauresque, etc., suitable aniline dyes are largely depended upon, often in combination, to produce the desired shade.

The Perfume—Avoid odorous substances which are readily oxidized—Terpene-containing oils are especially objectionable, as they rapidly deteriorate. The presence of fixatives, as musk and usually the oleoresins, is important.

The so-called Oriental or Far Eastern odors are very popular, in which the oils of patchouli and vertivert play an important part. Flowery odors are, however, much used, especially combinations under coined names, usually consisting of blends of such odors as rose, jasmine, tuberose, heliotrope, patchouli, carnation, etc. The perfume is first combined with a portion of the powder, usually the dry magnesium carbonate, because of its absorbent properties and then uniformly mixed with the other ingredients. There are machines available in which the perfume oil is sprayed on the powders during mixing and bolting, the entire process being conducted within a dust-tight mixer.

Perfumed Powder—The perfumed powder may be prepared as follows:

Powdered Florentine orris	40 parts
Magnesium carbonate, dry	40 parts

Mix by trituration and bolt through a silk sieve. Then add 2 to 4 parts of perfume oil, by trituration, adding it first to a small quantity of the powder, triturating thoroughly, then adding more powder and triturating until all is mixed. Finally sift again through silk.

Face Powder—White (a)

Precipitated chalk (bolted)	10 parts
Fluffy talc	10 parts
China clay (or kaolin)	10 parts
Magnesium carbonate	5 parts
Zinc oxide	5 parts
Zinc stearate	5 parts
Perfumed powder (see above)	7½ parts

Mix the first six powders, pass through bolting cloth several times and then incorporate the perfumed powder and again bolt.

Face Powder—Flesh or Naturelle (b)

Replace one-half of the white precipitated chalk in the above formula with *pink chalk* (see page 1233) and proceed as directed above.

[2] From Barrett Manufacturing Company.

Face Powder—Medium Grade (c)

Talc	32 parts
Kaolin	20 parts
Magnesium carbonate	4 parts
Precipitated chalk	5 parts
Zinc stearate	10 parts
Perfumed powder	7 parts

All ingredients but the zinc stearate must be bolted, then mixed in a mixer. Bolting would take out the zinc stearate. The color and perfume may be incorporated with the chalk.

Face Powder—Good Grade (d)

Talc	40 parts
Kaolin	20 parts
Zinc stearate	10 parts
Magnesium carbonate	10 parts
Precipitated chalk	5 parts
Colored chalk	5 parts
Zinc oxide	5 parts
Powdered orris	5 parts
Jasmine oil	0.56 parts
Musk ambrette (in the proportion of 2 grains in 10 pounds)	

Liquid Face Powder

(*a*)	Distilled water	9 fl. oz.
	Glycerin	1 fl. oz.
	Alcohol	1 fl. oz.
	Trisodium phosphate	⅛ oz. av.
	Agar-Agar	⅛ oz. av.
(*b*)	Zinc Oxide	4 oz. av.
	Precipitated chalk	1 oz. av.

Dissolve the agar-agar in the water with the aid of heat. When completely dissolved, add the trisodium phosphate, and when cold, the alcohol, glycerin, and the mixture marked (*b*). Shake well before using.

TALCUM POWDERS

Use only light fluffy talc, free from earthy odor and dead white.

Avoid a "silky sheen" variety of talc. Talcum powder may be 100 per cent talc. If the powder is to be "borated" use at least 5 per cent of boric acid (impalpable type). Orris root is desirable as a fixative. Zinc stearate adds adhesive qualities. Talcum powders may be colored as already described under *Face powders*, by the use of colored talc.

Talcum Powder (White, Borated)

Talc	18 lb. av.
Boric acid	5 per cent
Orris root	5 lb. av.
Perfumed oil (as desired)	4 oz. av.

Mix and bolt.

Talcum Powder (Pink, Violet)

Use the above formula, replacing sufficient talc with pink-colored talc as desired and perfuming with violet perfume oil.

Talcum Powder (With Zinc Stearate)

Ten per cent of the talc may be replaced with zinc stearate in any of the above formulas but such mixtures must not be bolted as it will separate the stearate.

HAND LOTIONS AND CREAMS

Undue exposure to winds and sun, or the frequent use of soap and water, as in the housework of the home, frequently causes a roughness of the skin which may often be relieved by the application of one of the so-called "hand lotions".

These are usually slightly mucilaginous preparations, mildly antiseptic or healing, and attractively colored and perfumed. The following formulas are typical:

Tragacanth Cream

Powdered tragacanth	5 drachms
Alcohol	12 drachms
Glycerin	6 fl. oz.
Water	24 fl. oz.

Color and perfume as desired.

Mix the tragacanth, alcohol, and perfume in a mortar and add the water, with brisk trituration. Set aside overnight and strain.

Benzoin Lotion

Tincture of Sumatra benzoin	3 fl. oz.
Glycerin	4 fl. oz.
Rose water, to make	1 pt.

Mix the glycerin and rose water in a bottle and shake well. Then very carefully pour the tincture on the mixture and slowly invert the bottle without shaking, until the benzoin is incorporated.

Tragacanth Hand Lotion

Tragacanth (preferably whole)	2 dr.
Boric acid	4 dr.
Glycerin	4 fl. oz.
Alcohol	4 fl. oz.
Water	24 fl. oz.

Color and perfume as desired.

Dissolve the acid in the water, with heat, add the tragacanth, and macerate with frequent stirring until uniformly mixed. Then strain through muslin or cheesecloth, add the glycerin and alcohol, and color and perfume.

Quince Seed Lotion

Quince seed[1]	4 drachms
Sodium borate	1½ drachms
Boric acid	1½ drachms
Glycerin	4 fl. oz.
Alcohol	4 fl. oz.
Water	24 fl. oz.

Perfume and color as desired.

Macerate the quince seed with one pint of water overnight, and strain. Dissolve the sodium borate and boric acid in the remainder of the water, add it to the mucilage and incorporate the other ingredients, including the color and perfume.

[1] Quince seed is frequently dirty and should be carefully but quickly washed in cold water before maceration.

Toilet Cream (a)

Quince seed	30 gr. in 5 fl. oz. of water
Ivory soap flakes	10 gr. in 2 fl. oz. of water
Stearin-borax emulsion (see below)	2 drachms
Glycerin	4 drachms
Alcohol	3 drachms
Water, sufficient to make	8 fl. oz.

Add the quince seed to five ounces of hot water in a bottle, and shake frequently during twenty-four hours. Then strain. Dissolve the soap in two ounces of water, then add the stearin-borax emulsion (see next page) and stir until thoroughly mixed. Add the quince seed mucilage to which the glycerin has been added and stir again until mixed. After cooling somewhat add the alcohol to which the perfume has been added, and then sufficient water to make eight fluidounces.

Stearin-Borax Emulsion

Sodium borate	1¼ oz. av.
Stearic acid	2 oz. av.
Water	1 pt.

Dissolve the sodium borate in hot water, add the stearic acid, heat and stir until they have combined. It takes only a short time (10 to 15 minutes), using a "double boiler" or other form of water bath throughout the whole operation.

Toilet Cream (b)

(*a*)	Stearic acid	1400 gr.
	White beeswax	600 gr.
	Water	1 pt.
	Melt on a water bath and mix thoroughly.	
(*b*)	Neutral soap	1400 gr.
	Sodium borate	600 gr.
	Sodium benzoate	280 gr.
	Boric acid	280 gr.
	Water	4 pt.

Form a solution and add to *a*, producing an emulsion.

(*c*)	Quince seed	10 oz. av.
	Water	3½ gal.

Make a mucilage and add *d*, then incorporate with *a* and *b* and finally add *e*.

(*d*)	Glycerin	1 pt. 14 fl. oz.
(*e*)	Alcohol	1 pt. 14 fl. oz.
	Tincture of Sumatra benzoin	4 fl. oz.
	Perfume	1 fl. oz.
	Water to make 5 gallons of finished product (2 pt. 15 fl. oz. needed)	

Part I

Almond Cream (a)

Lard	12 oz. av.
Expressed almond oil	4 oz. av.
Potassium hydroxide	2 oz. av.
Stearic acid	8 oz. av.
White wax	1 oz. av.

Warm the lard and almond oil in a porcelain dish, on a water bath, until uniformly melted. Dissolve the alkali in 20 fluidounces of water, add to the melted fats and heat on the water bath for two hours, with constant stirring.

Then add 8 fluidounces of boiling water to the soap and afterwards a melted mixture of the stearic acid and white wax. The soap solution must be on a

bath of boiling water when the stearic acid mixture is added and the whole actively stirred until perfectly smooth, while the heat is continued.

Part II

Sodium borate	1 oz. av.
Boric acid	0.5 oz. av.
Sodium benzoate	0.5 oz. av.
Hot water	80 fl. oz.

Dissolve the salts in the hot water, on a bath of boiling water and keep hot until ready to mix with part I.

Part III

Quince seeds (selected)	8 oz. av.
Boiling water	160 fl. oz.
Glycerin	12 oz. av. (by weight)

Add the quince seeds to the water and heat on a bath of boiling water for one-half hour, then strain through muslin and add enough boiling water to restore the 160 ounce volume. Now add the glycerin, mix well, and again strain to remove any brown particles.

Now add part I to part II, stirring until uniform, and thoroughly incorporate the quince seed solution (part III), and beat in an emulsion machine until cold.

When cold add the perfume dissolved in 25 fluidounces of alcohol, and enough water to make 4 gallons, stir again, set aside for one-half hour, beat up again, very thoroughly, in the emulsion machine, and bottle.

Perfume—Use any desired perfume as lilac, jasmine, lily, rose, etc., in the proportion of 0.5 oz. to 1 oz. per (5 gal.) 640 oz.

Mixture I **Almond Cream (b)**

Flake tragacanth	6 lb. av.
Water	20 gal.

Macerate for four days and strain. Then add:

Boric acid	5 lb. av.
Glycerin	3 gal.
Denatured alcohol (Formula 39)	8 gal.
Benzaldehyde	5 fl. oz.
Oil of rose geranium	5 fl. oz.
Water	40 gal.

Beat this mixture for two hours in a mechanical mixer.

Mixture II

Expressed oil of almond (or oil of persic)	6½ pt.
Powdered acacia	7½ lb. av.

Mix thoroughly in an emulsion machine, then add 1 gallon and 3½ pints of water and heat for one-half hour. Now add 1 gallon of mixture I, beat for one-half hour, and then slowly add the remainder of mixture I, running the beater slowly. Finally strain.

Toilet Lotion

Quince seed	2 oz. av.
Boric acid	11 dr.
Liquefied phenol	60 min.
Glycerin	1 pt.
Starch glycerite (U. S. P.)	1 pt.
Alcohol	8 fl. oz.
Triple extract violet	2 fl. oz.
Water to make	1 gal.

Macerate the quince seed in one pint of water overnight and strain. Dissolve the boric acid in one-half gallon of boiling water and add the quince seed solution. After macerating for twenty-four hours, strain through Canton flannel, and add the glycerite of starch, previously mixed with the glycerin and liquefied phenol. Mix the extract of violet with the alcohol and add in small portions, agitating briskly after each addition to prevent precipitating the starch. Lastly, add sufficient water to make one gallon, and strain through flannel.

Quince Jelly Hand Lotion

Quince seeds	4 dr.
Boric acid	2 dr.
Glycerin	8 fl. oz.
Orange flower water	4 fl. oz.
Tincture of benzoin	2 fl. oz.
Alcohol	4 fl. oz.
Water, sufficient to make	2 pt.

Macerate the quince seeds in 8 fluidounces of water overnight, strain, add the other ingredients and enough water to make 2 pints.

SKIN CREAMS

Three outstanding types of skin creams are in use today although each may be further subdivided into many other special varieties. They are *fatty creams*, *vanishing creams* and *rolling creams*.

Fatty Creams—The term "cold cream" is often commercially applied to a cream without its being a true cooling cream, simply because of the value implied by the name to the buying public. A true "cold cream" is one made from an absorbable oil and one in which water has been incorporated through emulsification. Such a product has been known and used for centuries, in fact, its origin is attributed to Galen and it is sometimes called "Galen's Cerate". This formula, with little change, is still official in the Pharmacopœia under the title "Ointment of Rose Water" and is typical of the best cooling and healing cream. A few years ago because of the cost of the expressed oil of almond from which the official cream is made and also because of its tendency to become rancid, someone prepared a cream somewhat similar in character but replacing the almond oil by liquid petrolatum. This was originally called "theatrical cream" as it was used almost exclusively to remove the grease paint used in theatrical make-up.

Before long, however, the name "cold cream" was applied to this petrolatum product and it is largely sold today under that label. The petrolatum cream is an excellent cleansing cream to use after motoring or when exposed to dust or dirt and finds a valuable place in the toilet, but it is not a cooling cream since the petrolatum is not absorbed as are the vegetable oils.

If the pharmacist wishes to market a true cold cream for general use which will give splendid satisfaction to customers who suffer from sunburn in summer or chapped hands or face in winter, the Pharmacopœial formula may be taken as a basis for the product but the almond oil may be replaced by expressed oil of peach or apricot kernels (commercially known as *oil of persic*) and the rose water may be replaced by distilled water and an appropriate perfume added. A smaller amount of wax and spermaceti is also desirable for toilet purposes as the official cream is too firm. A final necessity if the cream is to give satisfaction, is to market the product in pure tin collapsible tubes. If sold in a jar, the water will quickly evaporate and the fat become rancid but in a tube it will retain its softness and will not readily deteriorate. A typical formula is as follows:

Toilet Cold Cream (True)

Spermaceti	100 Gm.
White wax	100 Gm.
Oil of persic	560 Gm.
Sodium borate	5 Gm.
Distilled water	190 cc.
Perfume, as desired.	

Melt the spermaceti and white wax together on a water bath, add the oil, and, when uniformly melted, slowly incorporate the warmed solution of sodium borate in the water, stirring constantly. Finally add the perfume oil (such as rose, jasmine, lilac, carnation, trefle, arbutus, or such other as may be acceptable to the trade), remove the heat and stir continuously until cold. Then pour into collapsible pure tin tubes and close with a stiff metal clip. Preferably use a tube with the label embossed upon it, if it is to be sold successfully as a toilet cream.

Avoid the use throughout of all iron vessels or utensils.

Theatrical Cold Cream (a)

White wax	150 Gm.
Heavy liquid petrolatum	650 cc.
Distilled water	240 cc.
Sodium borate	9.6 Gm.
Perfume, as desired.	
To make	1000 Gm.

Melt the wax with the petrolatum in a porcelain or enameled dish on a water bath. Dissolve the sodium borate in the water, warm it to the same temperature as the fats, and add to the fats with constant stirring. Then add the perfume and immediately pour into ointment jars or tubes. Avoid all contact with iron.

Theatrical Cold Cream (b)

"Snow white mineral jelly—No. 15"[1]	8 lbs. av.
White wax	2 lbs. av.
Sodium borate	1½ oz. av.
Water	1 gal.
Perfume, as desired.	

Prepare as directed for Theatrical Cold Cream (a).

Theatrical Cold Cream (c)

Anhydrous wool fat	10 Gm.
Paraffin	10 Gm.
White wax	25 Gm.
Heavy liquid petrolatum	105 Gm.
Distilled water	50 cc.
Sodium borate	1.25 Gm.
Pink color (oil), a sufficient quantity.	
Perfume, as desired.	

Melt together the wool fat, paraffin, wax, and liquid petrolatum, in a porcelain or enameled dish on a water bath. Heat the water almost to boiling and dissolve the sodium borate in the solution. Add the perfume and color to the melted oils and wax mixture and then pour the hot water solution into the oil mixture, stirring constantly while heating until it is perfectly emulsified (about 10 minutes), using no iron apparatus unless tinned.

Then withdraw the heat and stir until cold enough to pour into jars or tubes.

[1] Obtainable from the Oil Products Company, New York.

Theatrical Cold Cream (d)

Heavy liquid petrolatum	80 cc.
Paraffin	10 Gm.
White wax	30 Gm.
Sodium borate	2 Gm.
Distilled water	80 cc.

Prepare as directed under Theatrical Cold Cream (a). Stir the emulsified mixture one minute before pouring.

Skin Food

White wax	4 oz. av.
Spermaceti	3 oz. av.
Hydrous wool fat	5½ oz. av.
Expressed oil of almond	1 pt.
Rose water	6 fl. oz.
Borax	40 gr.
Oil of rose	30 min.
Oil of ylang-ylang	30 min.

Prepare as directed under Toilet Cold Cream (true), page 1239.

Vanishing or Disappearing Creams—Creams of this character are primarily mixtures of potassium, ammonium, or sodium stearate and water with the addition of more or less glycerin and some free stearic acid, also a suitable perfume. The larger percentage of these creams being water they dry quickly, and to retard this, glycerin is usually added in amounts not exceeding 15 per cent.

Vanishing creams are used primarily as a base upon which to apply face powder. When rubbed upon the skin they disappear but leave a surface to which face powder will adhere. All ingredients should be of the highest grade. It is particularly important that the stearic acid be pure and cold pressed; the consistence being such that it may be crumbled to a powder between the fingers. Vanishing cream should be marketed in jars which can be tightly closed or preferably in pure tin, collapsible tubes. *All vessels or utensils of iron must be avoided,* only porcelain or enamel dishes being used.

Vanishing Cream (a)

Stearic acid	50 Gm.
Oleic acid	10 Gm.
Potassium hydroxide	2.5 Gm.
Distilled water	200 cc.
Perfume, as desired 1 cc. (more or less).	

Melt the stearic acid on a water bath, heated to a temperature of 85° C. Dissolve the alkali in the water, warm the solution to 85° C. and gradually pour the warm solution into the melted acid, stirring briskly. Continue the same temperature and active stirring for ten minutes to insure a complete saponification and absence of free alkali. Then remove the heat but continue the stirring until cold, at the same time incorporating the perfume. The cream should afterwards be beaten for several hours, preferably by mechanical means, and then placed in jars or tubes.

Vanishing Cream (b)

Stearic acid	1 oz. av.
Glycerin	1 oz. av.
Distilled water	4 fl. oz. 6 fl. dr.
Sodium borate	8 gr.
Potassium carbonate	16 gr.
Perfume, as desired	45 min.

Prepare as directed under vanishing cream (a), mixing the glycerin and water together.

Vanishing Cream (c)

Powdered boric acid	20 oz. av.
Sodium benzoate	2 oz. av. 126 gr.
Tragacanth (whole)	12½ gr.
Sodium bicarbonate	4¼ lb. av.
Stearic acid	138 lb. av.
Heavy liquid petrolatum	75 oz. av.
Glycerin	75 oz. av.
Lilac perfume oil	1 lb. av.
Water	11 gal.

Macerate the tragacanth in 6 gallons of the water for twelve hours or overnight. Dissolve the boric acid, sodium benzoate, and the sodium bicarbonate in the tragacanth solution and add 5 gallons of hot water.

Melt the stearic acid, add the glycerin, and the liquid petrolatum and then incorporate the aqueous solution already prepared, stirring constantly. Stir with a mechanical stirrer for one-half hour, add the perfume, again stir for a half hour and finally pass it through an ointment mill.

Rolling Creams—These are preparations of freshly precipitated casein from milk, usually colored pink. They must contain a preservative such as formaldehyde to prevent decomposition and should be marketed in jars which close tightly to prevent evaporation.

Their distinctive feature is their apparent disappearance when rubbed on the skin, followed immediately, on further rubbing, by rolling into small particles which carry with them the dust and dirt which has collected in the skin pores.

A typical formula is as follows:

Rolling or Massage Cream

Fresh rich milk	128 cc.
Solution of formaldehyde	0.125 cc.
Liquid perfume color (red)	0.2 cc.

Mix thoroughly, warm gently to 50° C. on a water bath and stir in quickly a solution of 2 Gm. of powdered sodium borate in 10 cc. of distilled water. Warm the mixture to 55° C. and strain through unbleached muslin, previously wetted.

Now prepare a hot solution of 4 Gm. of powdered alum in 16 cc. of distilled water, strain through cotton and add to the milk while boiling hot, stirring it in slowly, keeping the temperature at about 55° C. When cool, and the supernatant liquid is colorless, collect the precipitate on a strainer. Allow the precipitate to drain, wash thoroughly with water, again drain, and then press until the product is of proper consistence.

Finally, incorporate 0.3 per cent of finely powdered sodium bicarbonate, 1.5 per cent of finely powdered sodium benzoate, 3.5 per cent of impalpable boric acid and sufficient of the selected perfume (about 40 grains per pound).

DEPILATORIES

Depilatories are usually caustic applications, in which barium sulphide, calcium sulphide, or strontium sulphide enter into the composition of the preparation. They act by dissolving the cellular structure of the hair and are always more or less irritating to the skin.

They are usually marketed in a combination set consisting of a bottle of the sulphide mixture, which is kept dry and tightly-stoppered; a shallow

glass dish and a mixing spoon of horn or celluloid are included in the package. The directions suggest the adding of sufficient water to a small amount of the powder, in the dish, to form a paste and the spreading of this on the surface from which the hair is to be removed. The paste is allowed to remain for from three to five minutes and then scraped off bringing the hair with it. Cold cream is then to be applied to prevent any irritation and a box or tube of this usually accompanies the outfit when sold.

Typical formulas are as follows:

I

Barium sulphide (yellow)	20 Gm.
Powdered soap	5 Gm.
Powdered talc	32 Gm.
Wheat flour	32 Gm.
Benzaldehyde, enough to perfume.	

Mix.

II

Barium sulphide (yellow)	15 Gm.
Starch	5 Gm.

Mix.

III

Barium sulphide (yellow)	10 Gm.
Zinc oxide	5 Gm.
Wheat flour	5 Gm.

Mix.

IV

Best shaving powder (dry)	6 Gm.
Barium sulphide	8 Gm.

V

Shaving powder (dry)	5 Gm.
Calcium sulphide	5 Gm.

Depilatories in the form of pastes are now being offered. The decomposition of the sulphide is much more rapid in this form, however, and they are of doubtful practicability.

Cyclopedia of Perfumery (Parry).
Preparation of Perfumes and Cosmetics (Durvelle).

PART VII

THE RESPONSIBILITY OF THE PHARMACIST UNDER THE LAW

CHAPTER LXXVIII

COMMERCIAL LAW

FOR his own protection, and the protection of the community which he serves, the pharmacist should have a general knowledge of certain features of the law. Not only must he be familiar with the Federal and State statutes concerning the possession and dispensing of certain commodities in which he deals, such as poisons, drugs, opiates and alcoholic liquors, but he finds that many rules of the "common law", either as applied directly or as incorporated in the statute law of his State, seriously concern him in the management and development of his business.

Business Laws—The pharmacist should understand the general principles of the laws of contract, so that he will realize his responsibility when he undertakes a business obligation. The law of agency concerns him in the management of his employees. In deciding on the proper methods of conducting his business, raising capital, etc., he should know the fundamental principles of partnership and corporation law. As he is a dispenser of compounds which are highly dangerous when taken unadvisedly, he should be familiar with the law of negligence.

It is impossible in a general treatise of this kind to lay down in detail the legal subjects upon which the pharmacist should keep posted. All that can be attempted is a general outline.

Diversity of Laws—The American Union is composed of forty-eight distinct and separate sovereignties, each supreme within its own territory, excepting only so far as the American people by their Constitution have granted certain powers to the Federal Government. Most of the laws above referred to are governed entirely by State enactment, so that when it comes to examining details and niceties there are as many sorts of such laws as there are States. These are difficulties in the way of presenting a general treatment of this subject. There are however fundamental principles upon which the laws of nearly all the States agree. These are the principles of the "common law" of England, brought to this country by our forefathers, and either consciously or unconsciously followed since by the lawmakers of the several States as they sought to enact legislation to meet the changing needs of their communities. Therefore it is possible for the business man, by a study of the "common law" as it affects his business, to acquire, with a little help from a lawyer of his own State, a thorough grasp of the rules of law which must govern him in the management of his own affairs.

The Contract—In looking into the operation of the "common law" on this subject, it is found that first:

A Promise is not a Contract—It is difficult for the layman to grasp the idea that the law will not necessarily enforce a promise. Originally, only those promises which were written down and "under seal"—attested by the solemnity of a waxen or written seal—could be enforced. Later, the idea became established that if the person to whom the promise was made, lost something because of that promise, then it was not fair that the other party should break his word: so it became the law that if "consideration" passed—if value passed

from the promisee because of the promise made to him—then the contract should be as binding as though it had been made in writing and under seal.

Size of Consideration is not a Factor—The law is not interested in the value of the consideration. If there is consideration, the contract stands. One who has made a bad bargain may not invoke the law to escape from the consequences of that bargain. Contracts are supposed to be made by men "standing at arm's length" so that each one is required to use his wits to see that he makes the best terms possible for himself.

Fraud, However, May Make a Contract Void—A man may not profit by a contract into which he has induced another to enter by direct fraud or misrepresentation. Not every falsehood, however, is a fraud. The law on this point is undergoing some interesting changes; therefore the law of the State, where the contract is sought to be enforced, must be consulted.

Parties—The parties to a contract should be of full age and of sound mind; and the contract itself, to be enforceable, must be for the doing of a thing which is lawful.

Written Contracts—It is not necessary that contracts—save in a few excepted cases—be in writing. They may be made by action, or by word of mouth. If, however, the parties elect to put their agreement in writing, they must be careful to make the writing express the entire contract. Should there be a dispute later about its terms, they would each be relegated to whatever rights they held under the written instrument. Oral testimony of an understanding, enlarging or changing the terms of the contract as written down, would not be permitted to be presented at a trial to enforce rights under the contract. Ignorance of this principle has often led to serious loss.

What Contracts Must be in Writing—There are certain contracts, however, which the law requires to be expressed in writing. These are, generally speaking, contracts to guarantee or stand surety for another, contracts dealing with rights in real estate, and contracts for the sale of goods over a certain figure. The local State laws would have to be consulted on this point.

Remedies for Breach of Contract—If a contract is broken, the party wronged may in nearly all cases sue the other in a court of law, asking money damages as compensation for loss sustained. In some cases, however, where money damages would not compensate, he has the right to go into a court of equity and ask that the other party be compelled to carry out his agreement.

The contract most frequently dealt with, is that of

Agency—It is necessary for every business man to transact a great part of his work through agents. These may be general agents, with full power to act for their principals, or special agents, whose authority is limited by the contract of employment.

Duty Toward Agent—The principal owes to the agent the duty of payment for services rendered and remuneration for expenses properly incurred. If the agent is an employee, he has other obligations toward him, looking to his safety and health. These obligations are generally defined in the various workmen's compensation laws which are in force in practically every State. Under these laws, the principal is required to pay the employee compensation for injuries resulting from accidents suffered while engaged in the employer's business, such payment being made according to a schedule set forth in the law. The amount of payment depends upon the severity of the injury and the earning power of the employee. The principal is further required to take out insurance against the risk of liability for such payment.

Duty Toward Employer—The agent owes to the principal the duty of loyalty and service. He may not make a profit out of his employment, unless such profit is known to the employer; he may not "serve two masters".

Duty Toward Third Parties—The principal is bound by contracts made by the agent, within the scope of his *apparent* authority—even though such contracts be in direct violation of the agent's instructions—unless of course such violation be known or should be known by the person with whom the agent is dealing.

Agency by Estoppel—Even though an agent had no authority whatever, yet there may be a duty on the principal to speak out when he learns of the unauthorized act. If he fails to speak, and a third party by his silence is led to believe that the agent had authority, then the principal may be responsible on the "principle of estoppel".

Liability for Torts and Crimes—The principal is further liable to third parties for torts (wrongs) committed by the agent while seeking to further the employer's business, and this is also true whether or not such wrongs were committed in violation of instructions. A principal, however, is not criminally responsible for crimes committed by the agent, unless he instructed the agent to commit the crimes and thereby was a party to them.

The Partnership—The simplest form of doing business is that of personal ownership, which has few complications. If however, a partnership is formed, the law calls each partner both a principal and an agent—each partner is agent for all the others, within the scope of partnership business. It follows, therefore, that each partner can bind the partnership by contract; further, that each partner is responsible for all contracts made by the partnership or all debts incurred by it. This is true, irrespective of the size of the interest of the partner in the business—he is responsible for every cent of the firm's debts, no matter what that interest is, so long as he is a partner.

The Limited Partnership—If this liability is sought to be avoided, the device of a limited partnership may be employed. This is brought about by making application to the proper authority of the State, naming the contribution of each partner toward the business capital. Upon permission being received to operate as a limited partnership, the word "Limited" must be added to the firm name, to give notice to the world that there is limited liability on the part of certain partners. There must always be at least one general partner in a limited partnership, whose liability is unlimited.

The Corporation—The corporation is formed by authority of the state, which, upon application grants a charter to the incorporators. This charter states the powers of the corporation. It has no authority whatsoever outside of such powers.

Capital Stock—The capital stock of the corporation is divided into shares, and each stockholder holds a certain number of shares, evidenced by certificates of stock issued to him. The stockholders elect a board of directors and certain other officers, who conduct the affairs of the corporation.

Stock is either common or preferred. Common stock is the ordinary voting stock of the company. Its holders are permitted to share in the profits of the company, whenever dividends are declared by the directors. Preferred stockholders are entitled to receive their dividends before any payments whatever are made to the holders of common stock. The rights of all stockholders, so far as receipt of dividends is concerned, are printed on the certificates of stock issued to them.

Liability of Stockholders—In case a corporation becomes insolvent, stockholders are liable for only the amount of stock subscribed for by them, with certain exceptions with regard to banking corporations, etc., where the State law must be consulted.

Bonds—Bonds of corporations are evidences of debt, showing that money

has been borrowed. The terms of payment, the nature of the security, all questions of priority, etc., are stated on the bond. Bondholders of course must be paid in accordance with these terms, before any money is paid to stockholders.

Commercial Paper—Practically every State has enacted the "Uniform Negotiable Instruments Law". Its provisions state that "negotiable paper"—*i.e.*, bills of exchange, checks, promissory notes, etc., shall be negotiable by endorsement or delivery, so that a person who holds such paper for value before maturity shall have the right to proceed against prior parties on the paper without regard to any defences to payment which such prior parties might have. This of course would be true only when the holder did not have actual notice of such defences when he took the paper.

Notice of Dishonor—Formal "notice of dishonor" must be given to all prior parties on the note in order to hold them responsible. This notice must be given by a Notary Public, in a form called a "protest", and such protest must be made at or immediately after the actual dishonor of the note. Consult local statutes for manner and time for such notice. Unless such notice is given in strict accordance with the statute there can be no recovery under the law.

If one desires to endorse commercial paper without incurring any chance of liability thereunder, he should place over his signature the words "without recourse".

Negligence—A druggist is responsible, if anyone is injured by the negligent act of himself or his agent, provided such act is done within the scope of the agent's apparent authority. Negligence is the absence of proper care. What is proper care is a question depending on the facts in each case.

Liability for Error in Filling Prescriptions—If a pharmacist fills a prescription according to its terms, ordinarily he is not responsible if the medicine fails to cure or even does harm to the person taking it. Cases, however, may arise where a pharmacist is under a special duty to guard his customer from harm. Where unusual circumstances show that the physician giving the prescription could not have been aware of the toxic value of the ingredients prescribed, a duty rests upon the pharmacist to refuse to fill the prescription; and a failure to so refuse, in extreme cases, might make the pharmacist as well as the physician liable. The pharmacist, however, is under no compulsion to know the therapeutic value of the drugs prescribed.

A prescription should be filled by a registered pharmacist or a certified assistant personally, or by an employee under the direct personal supervision of the pharmacist or certified assistant. Violation of this rule may result in severe liability.

Preservation of Prescriptions—Prescriptions for *narcotic* and for *alcoholic liquors*, when once filled, become the property of the State. The pharmacist is merely their custodian. He is not allowed to destroy them nor part with them. He is required to keep them on a special file, subject to state inspection, for a specified time—generally five years.

Poisons—It is held, that a violation of a statute concerning the care or use of the thing which does the damage, is in itself negligence. It therefore is proper at this place to consider the special statutes concerning the sale of poisons. *A poison has been defined as any drug known to the pharmaceutical or medical profession, which is liable to be destructive to adult human life if taken in quantities of 60 grains or less.*

Forbidden to Send by Mail—Under Federal law the pharmacist is prohibited from transmitting poisons through the mails without special authority from the Postmaster-General.

Labels—There is a regulation in every State that whenever a preparation sold or delivered by a druggist is a poison, then the bottle, package or other carrier of the prescription must bear a label containing the name of the article, the word "poison" and the name and place of business of the seller. A druggist is further forbidden to sell any poison to a person without satisfying himself that the person understands the nature of the poison and intends to put it to proper use.

Deadly Poisons—In many jurisdictions special laws regulate the sale of poisons destructive to adult human life when taken in quantities of five grains or less. As to these, the druggist is obliged to keep a record of each sale in a "Poison Record", stating the name and address of the purchaser, the nature and quantity of the drug, the date when sold, and the purpose for which it is to be used. This record must be preserved, and be open to inspection by proper authority.

Other Special Legislation—Stringent laws govern the possession and sale of opiates and alcoholic liquors. These laws will be covered by other articles published herewith. The Federal Pure Food and Drugs Law of 1906, which prohibits adulteration or misbranding, will also be treated in a separate article.

Abortifacients—By virtue of a United States law, it is forbidden to send through the mails any drug or device tending to produce abortion or prevent conception. State laws provide, in most cases, that the same may not be advertised for sale or sold. An exception exists in the case of bona fide medical books and proper advertisements to the medical profession.

Advertisements—Recent laws have made the prohibition against wrongful advertisement more comprehensive and the penalty more stringent. Such legislation forbids any advertisement of drugs or wares "which shall be false or misleading in any particular".

CHAPTER LXXIX

SPECIFIC LAWS GOVERNING THE PRACTICE OF PHARMACY

THE legislature of every State has recognized the necessity of regulating the conditions under which a pharmacist may enter and subsequently practice his profession. *Such laws are police regulations, and are based upon the necessity of protecting the public against fraud in the handling of poisons, and potent or possibly harmful drugs and medicines.* The statutes dealing with the practice of pharmacy in the specific State under consideration should be consulted by those who desire exact information on this point.

These various State laws differ so materially among themselves, that it would be impossible in a treatise of this character to indicate their scope in other than the most general terms. The subject of a model pharmacy law has, however, been given careful study by a Committee of the A. Ph. A.[1], and a draft of such a law, embodying many conditions believed to be ideal, has been published[2]. This draft is not the law of any State, but that it may be readily available for consideration in the drafting of any proposed legislation and that it may serve as an ideal for future laws, it is copied here in full. It furthermore presents the principles embodied in all pharmacy laws.

In presenting this draft of a model pharmacy law, the A. Ph. A. Committee wishes it to be understood that it is intended only as a model and that it is realized that all sections may not be applicable everywhere. It embodies, however, many ideal features such as,

(*a*) The majority of the board of pharmacy to be graduates in pharmacy.

(*b*) That the pharmacy board shall be charged with the enforcement of all laws pertaining to pharmacy.

(*c*) That all who compound, sell or distribute potent drugs and poisons shall be required to prove qualification and also their place of business shall be registered by the board.

(*d*) The determination of the status of the physician, the veterinarian, and the "assistant pharmacist", in relation to dispensing potent drugs and the requirement that they prove their qualification.

(*e*) The law does not prevent the physician, dentist, or veterinarian from dispensing drugs in emergency.

(*f*) Adequate education and experience is required of registered pharmacists.

(*g*) The power to revoke a certificate for cause is granted the board, with the right of appeal.

(*h*) The act defines poisons and establishes regulations for their sale.

(*i*) Potent or poisonous drugs or medicines must be labeled to indicate the contents, and with the word "Poison", except when dispensed on the order of a physician, dentist, or veterinarian.

(*j*) The model law also covers the necessary regulations for the sale or dispensing of narcotic drugs and for the establishment of a standard of strength and purity in the drugs and medicines dispensed.

When a pharmacist has registered in one State it is frequently possible to then register in other States without a new examination. This privilege is granted through agreements of reciprocation which have resulted from the excellent service rendered by the National Association of Boards of Pharmacy. Reciprocity is now in force between the following States:

[1] The Committee consisted of Wm. C. Anderson, J. H. Beal, George M. Beringer, F. E. Stewart, F. H. Freericks, Chairman.

An Act to Regulate the Practice of Pharmacy and to Control and Regulate the Manufacture, Sale, and Distribution of Drugs, Chemicals, Poisons, and Potent Drugs

Be it enacted by the General Assembly of————————————

Section 1—Definitions: (*a*) the term "pharmacist" when not otherwise limited means a person licensed by the State Board of Pharmacy, to prepare, compound and dispense physicians' prescriptions, drugs, medicines, and poisons; (*b*) the term "pharmacy" when not otherwise limited means a place registered by the State Board of Pharmacy in which drugs, chemicals, medicines, prescriptions and poisons are compounded, dispensed, and retailed; (*c*) the term "drug dealer" means one who conducts a fixed place of business and who is registered by the Board of Pharmacy to distribute and sell drugs, chemicals, medicines and poisons in original packages only, as prepared by or under the supervision of a licensed pharmacist; (*d*) "chemicals" where not otherwise limited means the chemical materials of medicine; (*e*) "drugs" where not otherwise limited means all substances used as medicines or in the preparation of medicines; (*f*) "medicines" where not otherwise limited means drugs or chemicals or preparation thereof, in suitable form for the prevention, relief and cure of disease, when used either internally or externally by man or for animal; (*g*) "Pharmacopœia" when not otherwise limited means the latest edition of the Pharmacopœia of the United States of America; (*h*) "National Formulary" means the latest edition of that work as published by the "American Pharmaceutical Association"; (*i*) "Board" or "Board of Pharmacy" wherever used in this Act, unless otherwise specifically indicated, shall mean the State Board of Pharmacy of this state.

Section 2—There shall exist and be maintained within the state a State Board of Pharmacy with duties and powers as hereinafter defined and provided. The State Board of Pharmacy shall consist[1] of five (5) members, and the now existing State Board of Pharmacy heretofore appointed shall continue in office and act as the State Board of Pharmacy with all the duties and powers as herein provided until the terms of its present members, respectively, expire, the vacancies as they annually occur to be filled in keeping with the requirements of this Act. Hereafter in making appointments to the State Board of Pharmacy the appointees shall have been licensed Pharmacists under this or some former law of the state, for a period of at least five (5) years, and at the time of their appointment a majority of them shall be engaged in retail pharmacy. At least a majority of the members of the State Board[2] of Pharmacy shall be graduates of a college or school of pharmacy, and if the now existing State Board of Pharmacy is not so constituted the first occurring vacancies of the Board shall be filled with appointees meeting such qualification, except in the case of re-appointment of present members, and such qualification for at least a majority of the Board shall thereafter be maintained. Members of the State Board of Pharmacy to be appointed under this Act, shall be appointed by the Governor and shall serve for a term of five (5) years, or until their successors are appointed, and have duly qualified. Vacancies occurring in the Board other than by expiration of term shall be filled for the unexpired term only. The members of the Board shall be paid ten ($10.00) dollars per diem, and their necessary expenses while actually engaged in the performance of the duties of the Board. Annually, the State Pharmaceutical Association may from among its membership nominate five (5) candidates for the next occurring vacancy on the Board of Pharmacy, who shall meet the requirements as herein provided and from among the nominees when regularly submitted and certified by the president and secretary of the State Association, or from others having the necessary qualification, the Governor shall make his appointment for

[1] This number may be increased when deemed to be expedient.
[2] Where all members are desired to be engaged in retail pharmacy it can be so provided.

vacancies occurring in the Board of Pharmacy. Appointees to the Board of Pharmacy shall within thirty (30) days after their appointment take and subscribe an oath or affirmation before a properly qualified officer, that they will faithfully and impartially perform the duties of their office, which oath or affirmation shall be filed with the Secretary of State.

SECTION 3—The State Board of Pharmacy shall organize by electing a president, vice-president, secretary and treasurer all of whom shall be elected annually, and all but the secretary shall be members of the Board. The officers of the existing Board shall continue to so act until the term for which they have been elected shall expire. The Board shall have power to make rules and regulations for the proper performance of its duties, and the duties of its officers and employees and to carry out the provisions of this Act. The president of the Board shall preside at all of its meetings and in his absence or inability to preside the vice-president shall so act. The treasurer at stated periods as ordered by the Board shall receive and receipt for all moneys turned over to him by the secretary which are then to be paid by him into the State Treasury on or before the ——— day of every month, to the credit of a fund for the use of the State Board of Pharmacy, and he shall file with the Auditor of State a detailed verified statement of such receipts and payments. The compensation and expense of the members, officers and employees of the Board including the State Drug Commissioner shall be paid out of this fund, and out of such necessary appropriations toward said fund as shall be provided by the state. All disbursements on account of the Board shall be made upon requisition signed by its president and secretary and the warrant of the Auditor of State. The treasurer of the State Board of Pharmacy shall receive a compensation of $——— per annum, and shall be required to give a bond to the state in the sum of $——— with surities approved by the Board, conditioned upon the faithful discharge of his duties. The secretary of the State Board of Pharmacy shall be its executive officer, and shall be in charge of its offices. He shall make, keep and be in charge of all the records and record books required to be kept by the Board. He shall receive all fees to be collected under this Act and also collect, receive and receipt for all fines imposed under this Act in prosecutions brought by the State Board of Pharmacy, or under its direction, and at regular intervals, as ordered by the Board, shall pay the same over to the treasurer of the Board and take the treasurer's receipt therefor. He shall keep a register of all who under this Act are required to be licensed, and also of all places of business required to be registered hereunder, shall attend to all correspondence of the Board and shall perform such other special secretarial duties which the Board may charge him to perform, in keeping with the office of secretary. The officers, including the secretary of the State Board of Pharmacy, shall be empowered to administer oaths in connection with the duties of the Board. The secretary shall receive a salary to be fixed by the Board and all his necessary expenses incurred while in the performance of his official duties. He shall give a bond to the state in the sum of $——— otherwise similar to the bond required from the treasurer. The bonds required to be given by the treasurer and by the secretary and by employees under regulation of the Board, shall be deposited with the Secretary of State, and kept in his office. The books and registers of the Board as made and kept by the secretary or under his supervision, subject to the direction of the Board, shall be *prima facie* evidence of the matter therein recorded, in any court of law. The Board shall as an Examining Board meet at least four times each year in the city of ————————, or at such other place within the state as it may designate at any regular session.

SECTION 4—There is hereby created the office of a State Drug Commissioner who under the control and supervision of the State Board of Pharmacy, and in its name is directly charged with the enforcement of all laws coming within the jurisdiction of the Board. The State Drug Commissioner shall be appointed by the State Board of Pharmacy for a term of ——— years at a salary of $——— per annum. The State Drug Commissioner for at least five (5) years prior to his appointment shall have been licensed to practice pharmacy, and he shall be a graduate of a college or school of pharmacy. Vacancies in the office of the State Drug Commissioner shall be filled by the Board for the unexpired term. The State Drug Commissioner shall employ all necessary chemists, agents and clerical help for the proper conduct of his office, as may be from time to time determined by the State Board of Pharmacy, and all of his appointments shall be passed upon and approved or disapproved by the State Board of Pharmacy at its next regular session after the appointments are made. The State Drug Commissioner shall report upon his official duties to the State Board of Pharmacy at all its regular sessions, and at such other times as it may direct.

SECTION 5—It shall be the duty of the State Board of Pharmacy through the State Drug Commissioner and through its officers and employees appointed under its supervision for that purpose, to enforce all laws of the state, now or hereafter enacted which pertain to the practice of pharmacy, the manufacture, production, sale or distribution of drugs, chemicals and poisons, and to their standard of strength and purity. All fines and fees imposed and recovered under this Act shall be collected by and paid to the secretary of the State Board of Pharmacy, to be by him turned over to the treasurer of the Board, by whom the same are to be paid into the State Treasury. As an Examining Board it shall examine all persons in the art and science of pharmacy and its allied branches, who meet the necessary qualifica-

tion as herein provided and who make application for a license as Pharmacist, Assistant Pharmacist, Medical, Dental or Veterinary Dispenser, and Drug Dealer.

SECTION 6—The compounding and manufacture of drugs and medicines and their sale and distribution at retail or to consumers, when of potent or poisonous character as defined in this Act, shall be limited, exclusively to persons who are licensed for that purpose under the provisions of this Act, or under the supervision of such, provided that all persons now licensed within this state as Pharmacists or Assistant Pharmacists shall have all the rights which are granted to Pharmacists and Assistant Pharmacists, under this Act, when complying with the requirements thereof as hereinafter set out; and, provided further, that nothing contained in this Act shall be construed to prevent the personal administration of drugs and medicines carried or kept for emergencies, by licensed dentists, physicians, and veterinarians, in order to supply the immediate need of their patients. For the purpose of this Act, there shall be and are hereby made provisions for the licensing of Pharmacists, Assistant Pharmacists, Medical, Dental and Veterinary Dispensers, and Drug Dealers, each having the right hereinafter provided, and being subject to the limitations and restrictions as respectively made.

(*a*) A Pharmacist shall have the right to conduct a pharmacy for the compounding of medicines upon physicians' prescriptions, and for the manufacture, sale and distribution of drugs, medicines and poisons.

(*b*) An Assistant Pharmacist shall have the right to do all things that may be done by a Pharmacist, when in a pharmacy or place of business conducted under the supervisions of a pharmacist.

(*c*) Medical, Dental and Veterinary Dispensers, who must also be by this state licensed physicians, dentists, or veterinarians, shall have the right only to compound and dispense medicines which they prescribe for persons or animals under their medical treatment and such compounding and dispensing shall be strictly incident to the practice of medicine; dentistry or veterinary medicines.

(*d*) Drug Dealers, when conducting fixed places of business at least ———— miles distant from a pharmacy, shall have the right to distribute and sell potent drugs and medicines, and poisons as compounded and prepared under the supervision of Pharmacists licensed in this or other states, when properly labeled under the name of a licensed Pharmacist, known wholesale dealer, or manufacturer of drugs and chemicals.

SECTION 7—(*a*) Every applicant for a license as a Registered Assistant Pharmacist shall be not less than eighteen (18) years of age, and shall have at least three (3) years of practical experience in a pharmacy where physicians' prescriptions are compounded, and shall have successfully completed not less than one (1) year of instruction in a recognized college or school of pharmacy, for which credit shall be given as practical experience covering the time of college course pursued. Every applicant shall furnish proof of preliminary education equal to graduation from a high school of this state.

(*b*) Every applicant for a license as a Registered Pharmacist shall be not less than twenty-one (21) years of age, and shall be a graduate of a recognized college or school of pharmacy; shall have at least two (2) years of practical experience as a registered Assistant Pharmacist in a pharmacy where physicians' prescriptions are compounded, provided not more than one (1) of said two (2) years may be credited for a course successfully completed at a recognized college or school of pharmacy; shall furnish proof of preliminary general education equal to graduation from a high school of this state. It is hereby provided that a graduate of a recognized college or school of pharmacy lacking the required practical experience shall be permitted to take an examination on theoretical subjects at any regular examination of applicants and at any time after graduation, a record of the credits secured being made and kept by the State Board of Pharmacy, the practical examination in such case to be taken at the end of the required five (5) year period.

(*c*) Every applicant for registration as a licensed Medical, Dental or Veterinary Dispenser shall give proof of registration under the laws of the state, as a physician, dentist, or veterinarian.

(*d*) Every applicant for registration as a Drug Dealer shall be not less than twenty-one (21) years of age, and shall give proof of having attained at least a common school education, entitling to entrance of a high school in the state.

SECTION 8—Every applicant for registration as licensed Pharmacist and Assistant Pharmacist shall, to prove respective requisite knowledge, be examined to a proper varying degree in the subjects of chemistry, botany, materia medica, toxicology, and the theory and practice of pharmacy. Every applicant for a license as Medical, Dental or Veterinary Dispenser shall be examined for fitness to compound and dispense drugs and medicines to patients. Every applicant for a license as Drug Dealer shall be suitably examined for fitness to distribute and sell drugs and medicines; provided, however, that all licensed physicians, dentists and veterinarians of this state, who, when this Act takes effect, have been accustomed to compound and dispense medicines which they prescribe for their patients, may on application to the Board of Pharmacy within ninety (90) days from that date, upon

affidavit, setting out such fact, become licensed without examination, as such Medical, Dental or Veterinary Dispenser; and Drug Dealers who prior to, and at the time that this Act takes effect, have been engaged as such within the state, may within ninety (90) days from that date become licensed as such without examination, upon application to the Board of Pharmacy, giving satisfactory proof.

Section 9—Every person who hereafter desires to engage in pharmacy, with a view of becoming licensed as Assistant Pharmacist and as Pharmacist, shall, upon entering employment in a pharmacy register as an Apprentice with the State Board of Pharmacy, and for every such person the requisite practical experience shall be determined from the date of registration. A fee of fifty (50) cents shall accompany an application for registration as Apprentice, and a certificate shall be issued by the Board to such applicant. A person who before or after this Act takes effect may have served part of his apprenticeship in some other state not requiring such registration shall give proof of such service satisfactory to the Board. Persons who immediately prior to the time when this Act becomes effective have been employed in a retail pharmacy, with a view of becoming licensed as an Assistant Pharmacist or as a Pharmacist, shall for that purpose be given credit for the time so spent, in becoming registered as Apprentice.

Section 10—It shall be unlawful for any person to impersonate an applicant before the State Board of Pharmacy applying for registration or license under the provisions of this Act. Any person violating this Section shall be guilty of a misdemeanor, and upon conviction shall pay a fine of not more than one hundred ($100.00) dollars, or be imprisoned for not more than six (6) months or either, or both, in the discretion of the court.

Section 11—Persons desiring to enter a college or school of pharmacy shall give proof of the required general education prior to admittance thereto. The necessary proof of an entrance examination shall consist either of a certificate issued by the proper school authorities, or in successfully passing an examination before an Entrance Examiner, appointed by the Board for that purpose, at suitable compensation, to be allowed by the Board. The Entrance Examiner, under the authority of the Board, shall issue to such persons, properly qualifying and applying therefor, a certificate of preliminary education.

Section 12—The Board of Pharmacy shall make and promulgate the requirements for recognition of colleges and schools of pharmacy, subject to changes as may be deemed necessary by it. The requirements shall include provisions for a course of instruction, equipment and professorial staff.

Section 13—Every applicant for examination as Pharmacist shall pay an examination fee of ten ($10.00) dollars; every applicant for examination as Assistant Pharmacist, Medical, Dental or Veterinary Dispenser, or as Drug Dealer, shall pay an examination fee of five ($5.00) dollars. Certificates of registration and license shall be issued to Pharmacists on payment of a fee of five ($5.00) dollars, and to Assistant Pharmacists, Medical, Dental or Veterinary Dispensers, and Drug Dealers, on payment of a fee of three ($3.00) dollars. Certificates of Preliminary Education shall be issued at a fee of three ($3.00) dollars. Every applicant for reciprocal registration as Pharmacist, in addition to the fee covering cost of investigation, shall pay a fee of $——— and Assistant Pharmacist a fee of $———. All fees shall be paid to the State Board of Pharmacy, and by it covered into the State Treasury, to the credit of the State Board of Pharmacy.

Section 14—The State Board of Pharmacy may in its discretion grant certificates of registration as licensed Pharmacist or Assistant Pharmacist, to persons who furnish proof that they have been licensed as such, by examination in some other state, and that they are of good moral character, provided that such other state in its examinations require the same general degree of fitness as is required by examination in this state, and that the applicant qualifies in all other respects as is required for licensing by examination in this state, excepting that persons who have become licensed by examination in other states, prior to the time that this Act takes effect, and who have continuously, thereafter, been engaged in pharmacy, shall be required to meet only the requirements which existed in this state at the time when they became licensed in such other state, and, provided also, that such other state or states in like manner grant reciprocal licensing to Pharmacists and Assistant Pharmacists of this state. Applicants for reciprocal licensing in this state shall defray all necessary expense for making an investigation of their character, general reputation and pharmaceutical standing, in the state where they resided, such expense not to exceed the sum of ten ($10.00) dollars.

Section 15—The State Board of Pharmacy, in order to be informed and to determine the status of Boards of Pharmacy of other states desiring reciprocal licensing and in order also to be advised regarding the progress of pharmacy throughout the country, shall annually select one of its members to meet at the expense of the Board, with like representatives from other State Boards of Pharmacy. At such meetings, when arranged, there shall be discussed the degree of fitness which is required by the several State Boards of Pharmacy for granting licenses. Such representatives of the several State Boards of Pharmacy may adopt rules and regulations which shall guide the several Boards in the matter of reciprocal licensing, but abidence therewith shall be optional and at the discretion of the State Board of Pharmacy.

The State Board of Pharmacy through its representatives may with like representatives from other State Boards of Pharmacy join in creating and maintaining an association of representatives of the several State Boards of Pharmacy, to be engaged in the general advancement of pharmacy and in the keeping of records pertaining to the reciprocal licensing of Pharmacists, and at its discretion the Board may give to such association information which it possesses relative to such aims. The State Board of Pharmacy at an expense not to exceed one hundred ($100.00) dollars, per annum, may subscribe for and secure the service of an association engaged in the compilation of pharmaceutical information, knowledge and progress, specially adapted to secure efficiency in the work of the Board.

Section 16—The license of any Pharmacist, Assistant Pharmacist, Medical, Dental or Veterinary Dispenser or Drug Dealer, may be suspended or revoked by the Board of Pharmacy, when the license is proved to the Board to have been obtained by fraudulent means, or when the licentiate has been convicted of felony or is found by the Board to be guilty of gross immorality, or to be addicted to the liquor or drug habit to such a degree as to render him unfit to compound, sell or distribute drugs and medicines. Suspension or revocation of a certificate shall be only after due notice and hearing and for the purpose of such hearing the Board or any member thereof or its secretary is authorized to examine witnesses under oath and to take oaths or affirmations, and to reduce the testimony given in any such case to writing. Within thirty (30) days after the suspension or revocation of a license the licentiate may take an appeal to any court of record of the state, of competent jurisdiction, and pending such appeal the decision of the Board shall be suspended until the court renders judgment which shall be final in the case, and if the decision of the Board is not sustained, the licentiate shall be reinstated.

Section 17—There shall be kept in every Pharmacy and in every Medical, Dental or Veterinary Dispensary, a copy of the latest revision of the United States Pharmacopœia, and the latest revision of the National Formulary, and if homeopathic remedies are compounded and dispensed, a copy of the latest revision of the Homeopathic Pharmacopœia of the United States, which books must be open to the inspection of the Board of Pharmacy, the Drug Commissioner and their properly authorized agents and employees. Any person violating this Section shall, upon conviction, be fined the sum of ten ($10.00) dollars and the cost of prosecution.

Section 18—All certificates as Pharmacist and Assistant Pharmacist, Medical, Dental or Veterinary Dispenser, and Drug Dealer, shall at all times be conspicuously displayed in the place of business or dispensary where the licentiate is engaged as such. Any licentiate violating this Section, upon conviction, shall be fined the sum of ten ($10.00) dollars and the cost of prosecution.

Section 19—Every place in or from which drugs, chemicals, medicines, prescriptions or poisons are compounded, dispensed or sold at retail shall (except as otherwise provided by law) be a pharmacy or drug store in charge of and under the supervision of a licensed Pharmacist; a dispensary conducted for the need of patients only by a licensed Medical, Dental or Veterinary Dispenser; or a store conducted by and under the supervision of a licensed Drug Dealer. Every such place shall be annually registered in the month of January with the Board of Pharmacy, on application forms provided for that purpose by the Board, on request, and the Board shall thereupon issue a suitable certificate of registration which shall be conspicuously displayed in the respective place of business. Applications for registration as a pharmacy or drug store shall include information regarding the names of all pharmacists, assistant pharmacists and registered apprentices who are employed therein. Only places in charge of a licensed Pharmacist may use the title "Pharmacy", "Pharmacist", "Apothecary", or "Drug Store", and each must be under the separate management of a licensed Pharmacist who shall not engage to manage or supervise more than one such place, but nothing contained in this Section shall prevent a person from owning and conducting more than one pharmacy, provided each be under the separate supervision of a licensed Pharmacist. For the registration of every place herein required to be registered there shall be paid an annual registration fee of one ($1.00) dollar by the person desiring its registration. Any person failing to register his place of business as herein required, failing to have in charge of each pharmacy a licensed Pharmacist, who does not manage or supervise more than one pharmacy, or who otherwise fails to comply with the provisions of this Section, shall upon conviction be fined the sum of not less than ten ($10.00) dollars, nor more than fifty ($50.00) dollars for each separate offense.

Section 20—The Board of Pharmacy shall make from time to time uniform rules and regulations, which are to govern it and its officers, and the Drug Commissioner and all employees in the enforcement of this Act. It shall prescribe, publish and furnish all application forms for license or registration, which are required under this Act.

Section 21—It shall be unlawful for any person who is not a licensed Pharmacist, licensed Assistant Pharmacist, licensed Medical, Dental or Veterinary Dispenser, or Drug Dealer, or who is not under the direct and immediate supervision of either of such licentiates operating within their lawful spheres, to compound, manufacture, sell or distribute at

retail, or advertise to do so, any potent drugs or poison as hereinafter defined, or any other chemical, drug, or medicine, intended for internal or external use, excepting only that this provision shall not apply to the personal administration of drugs and medicines by physicians, dentists, and veterinarians, in keeping with Section 6 of this Act. It shall be unlawful for Medical, Dental or Veterinary Dispensers to compound, sell and distribute potent drugs, or poisons, except for use by bona fide patients, who are under their medical treatment. It shall be unlawful for any Drug Dealer to compound or manufacture potent drugs, poisons or preparations containing the same, and it shall be unlawful for such Drug Dealer to sell or distribute potent drugs and poisons, except in original packages as prepared by and under the supervision of a licensed Pharmacist of this or some other state, territory or the District of Columbia, properly labeled to meet all requirements of the law, and bearing the name of the original distributor or manufacturer. Any person violating the provisions of this Section shall be guilty of a misdemeanor, and upon conviction thereof shall be fined not less than ten ($10.00) dollars, nor more than five hundred ($500.00) dollars, or sentenced to imprisonment for not more than one (1) year, either, or both, in the discretion of the court.

Section 22—The term "Poison" shall mean to include all articles enumerated and defined in Schedule "A" and Schedule "B" hereinafter set out. The term "Potent Drug" shall mean all drugs and chemicals and their compounds and preparation which are not in Schedules "A" and "B", specifically, or by general inclusion defined as poison, but of which the adult medicinal dose is stated in standard works of medicine, materia medica, or toxicology, to be less than one fluidounce if liquid, and one avoirdupois ounce if solid.

Schedule "A" Poison

Arsenic and the compounds and chemical derivatives of arsenic, corrosive sublimate and other poisonous compounds and derivatives of mercury, phosphorus and its poisonous compounds, and derivatives, tartar emetic or other poisonous salts or compounds of antimony, hydrocyanic acid, prussic acid, potassium cyanide, other cyanides and prussiates or other poisonous compounds and derivatives of cyanogen, oil of bitter almonds containing hydrocyanic acid, opium and its preparations and derivatives, aconite and its preparations, belladonna and its preparations, calabar bean and its preparations, scopola and its preparations, strophanthus and its preparations; the following organic principles: aconitine, apomorphine, atropine, brucine, cantharidin, cocaine, codeine, coniine, digitalin, emetine, eucaine, gelsemine, homatrophine, hyoscine, hyoscyamine, morphine, diacetyl-morphine or heroin, ethyl-morphine or dionin, physostigmine or eserine, scopolamine, strophanthin, strychnine, veratrine or any of their chemical compounds, salts, or derivatives, or any other drug, chemical substance, or preparation which according to standard works on medicine, materia medica, or toxicology, is liable to be destructive to adult human life in doses of five grains or less.

Schedule "B" Poison

Cannabis, cantharides, Chinese blistering beetle, cocculus indicus, colchicum, cotton root bark, digitalis, ergot, gelsemium, hellebore, henbane, ignatia amara, phytolacca, nux vomica, veratrum, stramonium, savin, chloroform, ether, wood or methyl alcohol, white precipitate, red precipitate, silver nitrate, copper salts, salts of barium, lead salts, oxalic acid, mineral acids, arsenical solutions, iodine, tincture of iodine, carbolic acid, creosote, croton oil, oils of pennyroyal, rue, savin, or tansy, or any other drug, chemical, substance or preparation which according to standard works on medicine, materia medica or toxicology, while not considered as toxic in doses of five grains or less, is nevertheless liable to be destructive of adult human life in doses of sixty grains or less.

It is hereby provided that compounds and preparations containing poisons as defined in Schedules "A" and "B" in quantities of less than one adult medicinal dose to one-half fluidounce, if liquid, or one-half avoirdupois ounce, if solid, according to standard books on medicine, materia medica, or toxicology, shall not be regarded to be poisons and also that the provisions of this Act governing the sale and distribution of poisons unless otherwise provided by law, shall not apply to the sale or distribution of preparations or remedies which do not contain more than two grains of opium or more than one-fourth grain of morphine, or more than one-eighth grain of heroin, or more than one grain of codeine, or any salt or derivative of any of them in one fluidounce, or if solid or semi-solid preparations, in one avoirdupois ounce; or to plasters, liniments, ointments, or other preparations which are prepared for external use only, and when sold or distributed for use as medicines.

Section 23—Whoever knowingly sells or delivers to any person otherwise than in the manner prescribed by law, any poison as defined in this Act, or sells or delivers in the manner otherwise prescribed by law any poison as defined in this Act to a minor under sixteen (16) years of age, but without the written order of an adult, shall be fined not less than ten ($10.00) dollars, and not more than fifty ($50.00) dollars for each offense.

Section 24—Whoever sells or delivers to any person a poison as defined in this Act without having first learned by due inquiry that such person is aware of the poisonous charac-

ter thereof, and that it is desired for a lawful purpose or without plainly labeling the word "Poison" and the names of two or more antidotes therefor upon the box or package containing it, or if included in the list of Schedule "A" Poisons, delivers such poison without recording in a book kept for that purpose the intended use thereof, the date of its delivery, and the name and address of the purchaser, and the name of the dispenser, or fails to preserve said book for five (5) years and submit it at all times for inspection to proper officers of the law, shall be fined not less than ten ($10.00) dollars nor more than fifty ($50.00) dollars for each offense. Provided, that when poisons are dispensed in keeping with a written record made by a licensed physician, dentist or veterinarian and such written record is filed and retained by a pharmacist, physician, dentist or veterinarian for at least one (1) year, the requirements herein shall be satisfied when the container of the poisons so dispensed bears a number or mark corresponding with a number or mark on the written record, so that it may be readily identified, unless the prescribing physician, dentist or veterinarian directs that the label shall bear the word "poison".

SECTION 25—The violation of any provision of this Act for which penalties are not specifically prescribed shall be subject to a fine of not more than ———— dollars for each separate offense.

SECTION 26—All Acts or Sections heretofore enacted and now in force in this state, which are in conflict with this Act or any of its Sections are hereby repealed, provided that nothing herein contained shall be construed to amend or repeal any Acts or Sections which govern the manufacture, sale or distribution of narcotics.

The Harrison Narcotic Law and Regulations

The Act of December 17, 1914 (known as the Harrison Narcotic Law), as amended by Sections 1006 and 1007 of the Revenue Act of 1918 (these sections reënacted in the Revenue Acts of 1921 and 1924), controls the importation, manufacture, production, compounding, selling, dealing in, dispensing, and giving away of opium and coca leaves and all compounds, manufactures, salts, derivatives and preparations thereof. Every person engaged in any of the foregoing activities is required to register with the collector of internal revenue for his district and pay tax as provided in the Act. Classes of registrants with the special taxes imposed are as follows:

Class 1. The tax is at the rate of $24 per annum. It covers importers, manufacturers, producers, compounders and chemists.

Class 2. The tax is at the rate of $12 per annum. It covers persons buying and selling stamped packages of narcotic drugs or preparations produced by others.

Class 3. The tax is at the rate of $6 per annum. It includes persons selling narcotic drugs from the original stamped package, *i.e.*, prescription pharmacists.

Class 4. The tax is at the rate of $3 per annum. It applies to physicians, dentists, veterinary surgeons, and other practitioners lawfully entitled to distribute, dispense, give away, or administer narcotic drugs to patients, upon whom they in the course of their professional practice are in attendance.

Class 5. The tax is $1 per annum or any fractional part of a year. It covers manufacturers of and dealers in narcotic preparations and remedies not subject to stamp tax.

How to Register—Persons first engaging in any narcotic business must file application for registry and special tax stamp on Form 678 a with an inventory on Form 713 for each class in which registration is desired except classes 1 and 2. Blank forms are procurable from the collector for the district. Application on form 678 a must be made within the month within which business is commenced. Persons already registered must *on or before July 1* of each year file application for registry and special tax stamp on *Form 678* with an inventory on Form 713 for each class, forms being procurable in like manner. Collectors will mail blank forms to all registered persons annually between May 15 and May 25 without request. Failure of any person to receive these blank forms will be no excuse, however, for failure to make application for

reregistry and special tax stamp within the required time. Address the collector of internal revenue for the district if blank forms are not received.

Inventories—An Inventory on Form 713 is required for each class except classes 1 and 2. Ordinarily druggists will have no stock of taxable narcotic drugs in class 5. No inventory whatever is required of non-taxable (exempt) narcotic preparations and remedies. A single Form 713 may be used for classes 3 and 5 by listing the taxable narcotic drugs and preparations on hand with the notation "No taxable narcotic drugs on hand in class 5" written at the bottom of the list. Any date from January 1 to June 30 of the current year will be acceptable for the inventory required on Form 713.

How to Procure Narcotic Drugs—Every registered person, except dealers in non-taxable or exempt narcotic preparations and remedies only, is qualified to buy blank official order forms from the collector of internal revenue at a price of ten cents per book of ten, requisition therefor to be made on blank Form 679, obtainable from the collector for the district without charge. Only one book will be furnished at a time except to persons registered in class 1 to 2. Official order forms for the purchase of narcotic drugs may be filled only by persons qualified as manufacturers or wholesale dealers, except an order form calling exclusively for a one ounce quantity of an aqueous narcotic solution which may be filled by a druggist qualified in class 3. Order forms must be made out according to the instructions printed on the back of each form. They may be returned by the manufacturer or wholesale dealer if not properly prepared in every detail. The duplicate copy of every order form issued must be kept on file for a period of two years. The original of all order forms for one ounce quantities of aqueous solutions must be kept on file by retail dealers likewise for two years.

How Retail Pharmacists May Dispose of Narcotics—Pharmacists qualified only in class 3 may dispose of narcotic drugs only upon properly prepared prescriptions with the exception of one ounce quantities of aqueous narcotic solutions as above stated. Prescriptions for taxable narcotic drugs or preparations must be issued by registered physicians, dentists, veterinarians or other practitioners, and each prescription must be dated as of the date on which signed, shall be signed by the issuing physician, dentist, veterinary surgeon or other practitioner, and shall bear the full name and address of the patient, and the name, address, and registry number of the issuing practitioner. A physician may sign prescriptions for narcotics in the same manner as he would sign a check or legal document, as, for instance, J. H. Smith, John H. Smith, or John Henry Smith. Prescriptions for narcotics must be written with ink or indelible pencil or typewriter; if typewritten they must be signed by the practitioner with ink or indelible pencil. The pharmacist upon filling the prescription must preserve it in a separate file for a period of two years from the date indicated thereon. A narcotic prescription for taxable narcotic drugs or preparations must not be refilled and such prescription must not be filled in part. Neither is it permissible for a pharmacist to supply narcotics pursuant to telephone advice from practitioners without prescriptions whether or not prescriptions covering such telephone requests are subsequently received.

Each package of drugs or preparations put up in pursuance of a narcotic prescription must bear a label showing the name and registry number of the pharmacist, the serial number of the prescription, the name and address of the patient and the name, address and registry number of the practitioner writing the prescription. It is preferable not to use the stamped container in which drugs are purchased from the manufacturer or wholesale dealer for filling a prescription. However, it is permissible to use such a container provided the stamp thereon is so obliterated as to prevent its further use and a label is attached thereto bearing the foregoing data.

A narcotic prescription may be filled only if issued for legitimate medical purposes. If the pharmacist to whom the prescription is presented for filling has any knowledge or entertains any suspicion which would cause him to believe that the drugs will not be used for such purposes, he should not fill it. The mere presentation of a prescription issued by a registered physician or other practitioner does not compel the pharmacist to whom it is presented to supply the drugs requested. A prescription issued to a person for a narcotic drug for the purpose of satisfying his craving for the drug and not for any legitimate medical purpose does not come within exception (b) of section 2 of the law and must not be filled. Any pharmacist who fills such a so-called prescription may be held correspondingly liable with the physician who issued it. Prescription pharmacists should carefully guard against the filling of prescriptions issued for addiction purposes.

Public officials, such as officials of the United States, District of Columbia, the various States and cities, who, in the exercise of their official duties, dispense or handle narcotic drugs, are not thereby required to register and pay special tax. Prescriptions issued by such officials for narcotics for official patients must be prepared on blanks provided by the Government or Department of which the issuing practitioner is an official, or, if no special blanks are provided, such prescriptions must be prepared on official stationery. Each prescription must show the name and title of the officer by whom executed.

Non-Taxable (Exempt) Narcotic Preparations—Narcotic preparations and remedies exempt from the full requirements of the law under the provisions of Section 6 of the Act, as amended, may be sold without a prescription but a record thereof must be kept as follows:

Date of Sale	Name of Purchaser	Address	Name of Preparation	Quantity
.....	.....	.....	.....	.....
.....	.....	.....	.....	.....

Preparations and remedies which do not contain more than two grains of opium, or more than one-fourth of a grain of morphine, or more than one-eighth of a grain of heroine, or more than one grain of codeine, or any salt or derivative of any of them in one fluidounce, or, if a solid or semi-solid preparation, in one avoirdupois ounce, and which are designed for internal use, are under certain conditions exempt from tax and the provisions relating to the purchase, sale or distribution of taxable narcotic commodities. These conditions consist primarily in confining remedies and preparations to standard or recognized medicines. The regulations provide that the exemption applies only to ready-made preparations and remedies compounded in accordance with the United States Pharmacopœia, the National Formulary, or other recognized or established formula usually carried in stock by a dealer and sold without a prescription. The regulations guard against authorizing the sale as in exempt preparations of a simple dilution of a narcotic drug made by admixture with inert or nearly inert substances. Druggists will be held responsible for the sale of any so-called preparations which do not have distinct medical use, or which are sold for other than strictly medicinal purposes.

A person registered in class 3 must also be registered in class 5 in order to dispose of exempt preparations although the payment of the $1 tax is not required if tax in class 3 or any other class is paid at the same location. Exempt preparations may be dispensed on prescriptions and such prescriptions may be refilled. But the quantity of exempt preparations so disposed of must be

entered on the above record in the same manner as if no prescription is present. The Government does not furnish blanks for the keeping of records of exempt narcotic preparations.

There is no specified limit as to the quantity of exempt preparations which may be sold by a retail druggist to a consumer. However, such preparations may be sold as medicines only, and if there is any possibility of a requested quantity of such a preparation being used for other than legitimate medicinal purposes sale should not be made. A pharmacist would be liable to the penalties imposed by Section 9 of the Act if he sold any quantity of an exempt preparation knowing that it would be consumed for other than legitimate medical purposes, *i.e.*, for addiction purposes.

Classes 1 and 2—A pharmacist must be registered in class 2 if he desires to fill order forms of other registered persons for stamped packages of narcotic drugs and preparations purchased from manufacturers or wholesale dealers. The stock of stamped packages maintained for the purpose of sale on order forms must be kept separate from the class 3 stock. Daily entry of the purchase of every package for either the class 2 or 3 stock must be kept on Form 811a. Daily entry of the purchase of every package for the class 2 stock must be kept on form 811a. Daily record of the sale of each such package by a class 2 registrant must be kept on form 811b, and all packages contained in the class 2 stock, needed in prescription work by a druggist registered in classes 2 and 3 must be recorded likewise on form 811 b as transferred to class 3. A wholesale monthly return on the same Forms, together with a statement of stock and totals of receipts and dispositions on Form 811 must be sworn to and transmitted to the collector of internal revenue for the district on or before the 15th of the month subsequent to that for which rendered in the manner provided in the instructions and regulations printed on Form 811.

Retail pharmacists desiring to fill order forms of other registered persons with packages of their own manufacture, production, or packing must be registered in class 1 as manufacturers. Each package manufactured, produced or packed must be separately stamped. The tax is at the rate of one cent per ounce or fraction thereof on the gross contents of the package. The stamps are procurable only by class 1 registrants. Requisitions therefor on Form 786 should be made to the collector for the district. Stocks of narcotic drugs used for class 1 purposes must be kept separate from all other stocks. Manufacturers must keep daily records on Form 810 a of all receipts for the class 1 stock and of all narcotic drugs and preparations produced. They must also keep a daily record of all dispositions and all drugs used for production on Form 810 b. Monthly returns on these forms with a summary on Form 810 must be made to the collector of internal revenue similarly as monthly returns are required from wholesale dealers but in accordance with the instructions and regulations printed on Form 810.

Inquiries Concerning Narcotics—Inquiries relative to registration or reregistration under the law and the payment of taxes thereunder should be addressed to the collector of internal revenue for the district in which the taxpayer is located. Inquiries dealing with the filling of individual prescriptions should be addressed to the Narcotic Agent in Charge of the division in which the druggist is located, or to the Commissioner of Internal Revenue, Washington, D. C. All other questions pertaining to the Harrison Narcotic Law, as amended, or the regulations thereunder, should be addressed to the Commissioner of Internal Revenue, Washington, D. C. All questions pertaining exclusively to the importation into, the exportation from, or the transhipment of narcotic drugs through the United States from one country to another should be addressed to the Federal Narcotics Control Board, Washington, D. C.

Narcotic Drugs Import and Export Act—The Narcotic Drugs Import and Export Act, improved May 26, 1922, as amended by the Act of June 7, 1924, limits importations of narcotic drugs to crude opium and coca leaves in sufficient quantities to meet medical and legitimate requirements only. No opium may be imported for manufacturing heroine. Permits to import are issued only to manufacturers having apparatus or equipment for producing drugs or medicines from opium or coca leaves. Permits to export are issued only to duly qualified manufacturers and wholesale dealers. All the permissive features of the Act are administered by the Federal Narcotics Control Board.

Obligation of the Retail Pharmacist Under the National Prohibition Act

A pharmacist, before using or selling liquor, must file application on Form 1404,[1] and bond when required (no bond is required for using 60 gallons of alcohol per annum, or using and selling 60 gallons of alcohol and 480 pints of bottled-in-bond spirits per annum). The application must state the kind and quantity of liquors to be used or sold in each quarterly period and the manner and purpose of such use or sale.

A duly licensed retail pharmacist, or a retail druggist through a duly licensed retail pharmacist in his employ, who holds a permit to use and sell, may sell liquor to a qualified permittee on approved purchase "Form 1410–A", when such sale is in ordinary trade practice considered a sale at retail. He may also make sales of liquor on properly executed official prescription "Form 1403". Such liquor must be labeled according to regulations, and the prescription canceled and filed as required. The pharmacist is held responsible for the authenticity of these prescription forms and should become thoroughly acquainted with the genuine form. A retail pharmacist selling intoxicating liquor as such is required to pay special tax as retail liquor dealer under the internal revenue laws.

A retail pharmacist holding permit to use intoxicating liquor may use intoxicating liquor for compounding medicinal preparations on physicians' prescriptions or otherwise, in quantities not exceeding 5 gallons in 90 days, provided such preparations contain no more alcohol than is necessary for extraction, solution or preservation, and must be unfit for beverage use. The pharmacist is to use his individual judgment as to the sufficiency of the medication, and is held strictly accountable as to the non-potability of such prescriptions or medicinal compounds. Such medicated prescriptions are not required to be written on "Form 1403", but must contain the patient's name and address and be filed on a separate file or with the prescriptions written on "Form 1403".

Retail pharmacists holding permits may sell alcohol, medicated according to one of the formulas in Regulations 60, in quantities not exceeding one pint without physicians' prescriptions to persons who do not hold permits. Each container of such medicated alcohol must bear a "poison" label.

A retail pharmacist holding a permit may use alcohol and wine in the manufacture of U. S. P. and N. F. preparations considered fit and unfit for beverage use. However, the U. S. P. and N. F. preparations considered fit for beverage purposes can only be sold subject to purchase "Form 1410–A" or official prescription "Form 1403". They may be used for compounding medicinal preparations on physicians' prescriptions or otherwise, medicated sufficiently to insure unfitness for beverage use.

Retail pharmacists who purchase and sell intoxicating liquor are required

[1] All forms mentioned may be procured from the Prohibition Administrator in your District, or upon application to the Prohibition Unit, Treasury Department, Washington, D. C.

to keep a record on "Forms 1455 and 1455–A", showing detailed entries of all intoxicating liquor received and sold by them, each transaction to be entered at the time of receipt or sale. A carbon copy or transcript of this record form must be forwarded to the Administrator before the 10th of each month succeeding the month for which the report is rendered.

Retail pharmacists holding basic permits must also render a report each month on "Form 1421" showing all information called for on this form, even though no liquor was received, possessed, sold or used during the month. This report must be made in triplicate, two copies being sent to the Administrator, as indicated in the preceding paragraph, and one copy retained by the permittee.

Obligation of the Physician Under the National Prohibition Act

A physician before prescribing, using or administering intoxicating liquor must file application on "Form 1404", stating specifically the privileges and quantities of liquor desired, and may receive a permit on "Form 1405", granting authority to prescribe intoxicating liquor on "Form 1403". He may also have the privilege of administering liquor to patients upon whom he is in attendance, and may also use the same for compounding, and may use alcohol for sterilizing purposes. All privileges desired may be requested in the same application form.

A physician holding a permit with the privilege of prescribing may secure from the Administrator a serially numbered book of 100 authorized prescription blanks on "Form 1403". Not more than one book to be issued in 90 days except by special authorization.

A physician should not prescribe on "Form 1403" except for the relief of some ailment from which the patient is known by the physician to be suffering. A physician shall not prescribe for any person within a period of ten days more than one pint of potable distilled spirits; one quart of wine; or any spirituous or vinous liquor containing more than one-half pint of alcohol. All prescriptions for liquor must be written on "Form 1403", except that in certain cases where a "*grave emergency*" exists, a duplicate prescription may be written on the ordinary prescription blank, when the requirements of the Regulations have been complied with.

Every physician who prescribes liquor is required to keep a record of such prescriptions in book "Form 1402".

The Federal Food and Drugs Act as it Relates to Drug Products[1]

The Act, as provided for therein, applies to all drugs which enter interstate or foreign commerce, or are made, sold, or offered for sale in any Territory of the United States (including the insular possessions), or the District of Columbia.

It should be understood that the term "drug" includes all medicines and preparations recognized in the United States Pharmacopœia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals.

The law provides in effect that a drug is adulterated if, when sold under a name recognized in the United States Pharmacopœia or National Formulary,

[1] The Food and Drugs Act is enforced by the Bureau of Chemistry of the Department of Agriculture of the Federal Government.

it differs from the standard laid down in these authorities, or if its strength or purity falls below the professed standard under which sold; and misbranded, if the labeling bears any false or misleading representation regarding the product or its ingredients, or any false and fraudulent statement, design or device regarding its curative or therapeutic effect.

The term "label" as used in the Act is held to include any printed matter that accompanies the package, such as box, carton, or bottle label, wrapper, booklet, circular, etc. And any literature, though it may not accompany the package, should not exceed in the impressions produced, what may properly appear in the labeling. The law does not require that a formula or list of ingredients be stated on the label of drug products, but it does provide for a declaration thereon of certain specified substances. The intent of the Act is that the purchaser be not misled in any particular. It is, therefore, essential that the impressions conveyed to the public by the terms of the labeling, in whatever manner they may be expressed, should be fully justified by the ingredients of the product. As Justice McReynolds, of the U. S. Supreme Court, recently stated in a decision "The statute enjoins truth".

In considering the label of a medicinal preparation the Bureau of Chemistry is accustomed to take for its guide the consensus of modern medical opinion; and in its interpretation of the label it is accustomed to place itself in the position of the average purchaser, who cannot be expected to make finely drawn distinctions. The Bureau does not consider as adequate authorities for therapeutic claims, statements based on personal belief, or testimonials in general, excerpts from dispensatories, medical works, or obsolete medical practices. It is the duty of the manufacturer to carefully consider whether the representations he makes are strictly in accord with the facts.

The printing of names of diseases or disorders on the labeling of a medicine for public sale conveys to the purchaser the impression that the product in itself is a competent treatment for the diseases mentioned. The names of diseases on a label, therefore, should be limited to those for which the article, in view of the recognized medicinal action of its ingredients, considered singly or in combination, is a treatment. Names of organs or portions of the body should not appear upon a label unless the product can properly be considered a treatment for any and all disorders to which such organs or parts may be subject. Representations of curative or beneficial effect conveyed by testimonials are subject to the same requirements as other therapeutic claims. A manufacturer must assume responsibility for all therapeutic claims made in this manner to the same extent that he does for promises of benefit made in his own words.

The wording of collateral advertising in newspapers and elsewhere should in no instance exceed, in the impressions produced, the terms of the labeling. This is also true of claims made by agents or otherwise. The Act does not authorize the Department to approve or suggest labels, formulas, trade names, or advertising literature, and any printed matter upon the label implying that such approval has been granted will be without warrant. Also, it is no longer permissible to use either the serial number or guaranty legend on the label or package of products that come within the jurisdiction of the Act.

Frequent inquiry is made regarding toilet preparations, and in this connection it may be stated that unless a toilet preparation is intended or represented, directly or indirectly, to be useful for the cure, mitigation, or prevention of disease it is not subject to the law, as will be evident from the definition of "drug" previously given. It is expected, however, that the manufacturer will exercise due care that such preparations do not contain any

ingredient that might be injurious to health. It should further be noted that the issuance of a trademark, copyright, or patent for a preparation does not exempt it from the provisions of the Act. In conclusion, attention is invited to the following important quotation from an opinion of the U. S. Supreme Court on the Act:

"The Statute is plain and direct. Its comprehensive terms condemn every statement, design, and device which may mislead or deceive. Deception may result from the use of statements not technically false or which may be literally true. The aim of the statute is to prevent that resulting from indirection and ambiguity, as well as from statements which are false. It is not difficult to choose statements, designs and devices which will not deceive. Those which are ambiguous and liable to mislead should be read favorably to the accomplishment of the purpose of the Act."

Therefore, in order to avoid possible conflict with the law, manufacturers should clearly understand that it is in their interest to see to it that only well warranted therapeutic or other statements appear upon labels of drug products. It is suggested as advisable that consideration be given to what should be eliminated from the label to bring about conformity with the law, rather than to use phraseology which might incur criticism.

Patent and Proprietary Medicines

Patents—A patent is a license issued by the United States Government, giving to the holder thereof the exclusive right to make, use, and sell the thing or process patented for a period of seventeen years. This license is issued by the Patent Office in Washington. In order to secure it, an applicant must file with the office an affidavit, with appropriate charts, drawings, models, etc., showing the exact composition of the thing or process which he has invented or discovered. "Letters patent" should issue only when the Patent Office is of the opinion that the invention or discovery is both novel and useful.

The right conferred by the letters patent is an exclusive right, and all others besides the patentee and his assignees are prohibited from infringing on that right during the life of the patent. At the expiration of the seventeen year period, the right passes to the public generally. Thereafter any person is at liberty to make, use, and deal with the thing or process patented, without any restraint whatever imposed by the patentee.

Proprietary Medicines—The manufacturer of a proprietary medicine takes the risk of its being made and sold by anyone who can copy it. Unless he is protected by a patent he cannot prevent anyone from dealing at will with the article.

Trademarks—The protection given to the owner of a trademark exists by virtue of common law, *i.e.*, irrespective of any right conferred by statute. If the maker of any article chooses to mark it with a distinctive device or brand, to designate the source or origin of the article, such device is a trademark, and it cannot be copied or used by anyone else without permission of the owner. The right to the exclusive use of the trademark, however, lasts only so long as the owner or his assignees actually make general use of it in trade. As soon as such use is discontinued, anyone may step in and use the trademark and the first one to establish his right to use it, would in turn be protected from subsequent infringement of the trademark by others.

For convenience in establishing one's right to the use of the trademark, a registration office is located at Washington. There, anyone who desires to employ any distinctive and original device in marking the goods put out by

him, may register such device, and the fact of such registration will be of assistance in showing that he is actually using such mark or device at that particular time. The fact, however, that such device is registered, gives no greater rights to the one using the same than he has by common law. He has the exclusive right to employ it only so long as he actually makes use of it in the general trade.

Trade Names—"Undoubtedly words or devices may be adopted as trademarks which are not original inventions of him who adopts them, and courts of equity will protect him against any fraudulent appropriation or imitation of them by others. Property in a trademark, or rather in the use of a trademark or name, has very little analogy to that which exists in copyrights, or in patents for inventions. Words in common use, with some exceptions, may be adopted, if, at the time of their adoption, they were not employed to designate the same, or like articles of production. The office of a trademark is to point out distinctively the *origin, or ownership of the article to which it is affixed;* or, in other words, to give notice who was the producer. This may, in many cases, be done by a name, a mark, or a device well known, but not previously applied to the same article.

"But though it is not necessary that the word adopted as a trade name should be a new creation, never before known or used, there are some limits to the right of selection. This will be manifest when it is considered that in all cases where rights to the exclusive use of a trademark are invaded, it is invariably held that the essence of the wrong consists in the sale of the goods of one manufacturer or vendor as those of another; and that it is only when this false representation is directly or indirectly made that the party who appeals to a court of equity can have relief. This is the doctrine of all the authorities."

Per Mr. Justice Strong, U. S. Supreme Court, in *Canal Company v. Clark*, 13 Wall. 311.

PART VIII

THE BUSINESS REQUIREMENTS OF PHARMACY

CHAPTER LXXX

BUSINESS ADMINISTRATION

THE Profession and the Business—Every profession has a business aspect. The clergyman, the physician, the artist—all must be compensated for their services. A part of this compensation lies in the satisfaction which the individual derives from the performance of the service and in the recognition accorded him by his fellowmen for his professional achievements, but there must also be remuneration in money if the professional man is to live and take care of his dependents. Giving professional service, therefore, of necessity involves an exchange of that service for profit which is just as much a "sale" as is the exchange of a commodity for profit in a mercantile establishment. There is a commonly recognized distinction between a professional man and a tradesman, as far as selling is concerned, namely that the professional man shall think of the service to be rendered first, and the profit, incidentally, whereas the objective of the tradesman is primarily profit.

The pharmacist serves in a dual capacity. He is both a professional man and a tradesman. In giving his professional services he should not forget profit but it must not be the primary consideration. On the other hand, in his merchandising, he is justified in placing profit first, for without it, he is unable to finance the service features of his profession and business.

It is therefore apparent that a pharmacist must know something about business as well as pharmacy and apply equal skill to both sides of his calling if he is to fill the niche which modern standards of living have created for him in this country.

Business itself is now classed as a profession because it no longer depends on guess-work or "rule-of-thumb" procedures. Many universities and colleges give special courses in business administration. Business scientists in these colleges and elsewhere have evolved the fundamental laws underlying commercial transactions and are continually engaged in researches designed to bring out more essential facts, determine causes, and study effects, to the end that those engaged in various divisions of business may increase their chances of success. It is recognized that business researches are just as important to the welfare of mankind as researches in chemistry and the medical arts. Both classes of research lead to greater knowledge, simplified procedures, and a higher type of civilization.

If business is looked upon as a profession also, the pharmacist may be considered as the practitioner of two professions—pharmacy and business, and it stands to reason that he should be well trained in both.

One important fact in connection with the business of pharmacy must never be lost sight of and that is the desirable prestige which professional pharmacy gives to the pharmacist. No matter how commercial a retail pharmacy may be, it always stands far above the most dignified mercantile establishments in the eyes of the public, because it is quite generally recog-

nized that the pharmacist is, by training and legal preferment, much more than an ordinary merchant. It is unfortunately true that some pharmacists do not conduct their businesses in a manner calculated to enhance this inherent prestige, and this adversely affects public opinion of pharmacists as a class. There are enough pharmacists, however, who realize the importance of the professional stamp upon their stores, even from a commercial viewpoint, to emphasize that feature whenever possible.

It is evident that the average merchant recognizes the value of the association of "drug" or "pharmacy" with "store", for all sorts of attempts have been made in recent years on the part of such merchants to take advantage of the public confidence in drug stores by giving their establishments a pharmaceutical aspect. Such terms as "drugless drug store", "medicine store", etc. have been used as signs over establishments of the general store type which sell package medicines and toilet articles, together with the usual non-pharmaceutical side lines and sundries that make up a large part of the stock of a modern legitimate pharmacy. This has gone so far that in the interest of the public health as well as in their own interest, pharmacists in several states have petitioned their legislatures to pass laws prohibiting the use of the words "drug", "drugless", "medicine", and similar words or phrases in connection with names of establishments that are not pharmacies in the legal sense of the word. A number of laws of this character have been passed.

Pharmacists who go into business should at all times emphasize the professional side of their calling even if it represents only 10 per cent of their total volume of business. It is their greatest asset, commercially as well as professionally, and should be protected and preserved for business reasons, if for no other.

The most successful pharmacists are those who have learned how to coördinate the professional and the business activities of their calling and have never given the general public an opportunity to question their status as pharmacists first and merchants only secondarily. The slogan now so frequently used: "Your druggist is more than a merchant" must be lived up to if it is to create any lasting impression upon the public.

The Need for Business Training—By far the larger portion of this book is devoted to the technical training required in the professional side of pharmacy but, for reasons already set forth, it has been considered necessary to introduce a section dealing with the problems of business as they apply to pharmacy.

Twenty-five years ago it would have required much argument to prove the necessity for training pharmacists in the science of business. It was only after a struggle that Joseph P. Remington, in 1900, established the first compulsory business course in a college of pharmacy. Today, however, the importance of such training is universally recognized and it is made a requirement in the model courses outlined in the Pharmaceutical Syllabus. It is but natural that the subject matter of the chapters on business in this book is particular rather than general. It deals with various phases of the science of business as applied to the conduct of a retail pharmacy. For a broad consideration of the fundamentals of business science, such as is given in the courses of graduate schools of business administration, the student is referred to other sources.

The ability to maintain efficient and progressive professional service in any pharmacy requires that it be conducted on a profitable basis. Profit will result only if the business is carried on with a due regard for economic and professional principles. This involves a knowledge of and continued search for facts. Knowing how to buy intelligently, display attractively, sell rapidly and abund-

antly, at prices that are fair to the consumer and profitable to the seller, may be considered as the chief ingredients of the *success formula* in merchandising.

The fact has been emphasized that profit is essential and the student of pharmacy will soon realize that while there is ample opportunity throughout the activities of every business day for the pharmacist with professional ideals to serve mankind, and also for those who enjoy business as a game to have their fill, yet all opportunity and satisfaction vanish when there is no financial profit.

The Necessity for Knowing the Facts about a Business—Coördination of the factors entering into what has been called the "*success formula*" is a prime essential. The *stock* of a store and the *buying policy* for example, should bear a reasonable relation to *sales*; the total *expense* must be known and compared systematically with sales figures.

If buying is in excess of sales, there is need for better buying judgment or for more capital; if expenses are mounting, a sharp reduction in some items of expense may be necessary, or perhaps a stimulation of sales is the proper antidote. Increased expenses or lowered sales volume will proportionally reduce and often wipe out profits.

The beginner in business who has received no special training, usually fails to recognize the importance of these basic principles. He does not realize the need of having the facts systematically assembled for study. Frequently, there is no definite plan and each problem is handled as it arises without relation to the last or to the next that is to follow. If, under such circumstances, there is ultimate success, it comes only at the expense of many embarrassing and often costly mistakes and, only too frequently, ventures which might have enjoyed extraordinary success, yield only a mediocre return and often end in financial failure.

Planning and Organization are Necessary—Business training as now recognized and taught in leading colleges and universities takes cognizance of the fact that guess work must give way to intelligent planning if the number of failures is to be lessened. An effort will be made in these chapters to point out and briefly discuss the essential planning required in the conduct of a retail drug business. It may help the student to carry in mind a picture of the factors entering into a successful scheme of organization, by recalling the form of organization of the U. S. Army in the late war.

In the stress of those momentous days when the finest brain and brawn of our country were being molded into an effective fighting force, Colonel Samuel P. Wetherill, Jr., worked out a plan of organization which was approved by General Pershing and his staff and put into effect throughout the entire American Expeditionary Force.

The plan was vividly pictured to every man in the army through a graphic chart, consisting of a soldier whose right hand typified the *division of command.* By means of the right hand an order is written or directions are given. The left hand typified the *intelligence department.* The left hand holds the map or notebook from which information is obtained on which to base the next move. The right foot typified the *attacking force* including infantry, cavalry, tanks, artillery, etc., for it is with the right foot that the soldier always takes the first step in an advance. The left foot represented the *supporting divisions,* the commissary, hospital and ammunition trains, etc., and it of necessity rests on solid ground. All of these elements were coördinated by the *head* thus completing the "man chart" of A.E.F. fame.

The same form of organization may be applied with equal effectiveness to a retail business. The head of the business, whether it be a corporation, a partnership, or a one-man store must coördinate the various factors to produce

a smoothly running machine. In order to accomplish this he must oversee the various tasks that make the machine run smoothly. In other words he *commands* his staff or himself, formulating policies and giving directions for the carrying out of these policies.

His *intelligence department* furnishes him with buying and selling information, knowledge of finances, general business conditions, and information about the goods he has for sale. The sources of such information may be salesmen, journals, newspapers, financial agencies and his own education.

The *supporting division* may be visualized as the store itself with its stock and all that pertains to it and the *attacking division* consists of the methods of exchanging commodities and service for profit, with proper aggressiveness and a due regard for the professional background of the retail drug business.

Summarized, the factors entering into the administration of a retail pharmaceutical business are:

1. Administrative organization as considered in this Chapter
2. The store or place of business.
3. The service and commodities offered for sale.
4. The methods of exchanging service and commodities for profit.

Administrative Organization

Under this heading will be considered the necessary qualifications of the owners or managers of a retail drug business. What must be their knowledge of business in general and how can they organize to the best advantage for financial success?

If the owner of a pharmacy is a trained pharmacist he will, of course, be prepared to carry on the technical portion of his calling. If he is not a pharmacist he must engage someone with the proper technical qualifications to act as the head of the business. The same is true of a corporation. In the case of a partnership, where one of the partners is not a pharmacist, the partner with pharmaceutical training must assume the responsibility of management in order to satisfy the legal requirements.

There is still a lack of uniformity in the pharmacy laws of the various States but all of them require that a pharmacy shall be in charge of a registered pharmacist at all times. Provision is made in some cases for temporary absence and in several States, notably New York and Illinois, it is now a legal requirement that the owner of a pharmacy must be a registered pharmacist. This law rules out corporation stores and non-pharmaceutical partnerships which were not already established when the law became operative. In all cases the technical training of those in charge of retail pharmacies is fixed by law, but the head of a business must be informed on all branches of that business if he is to retain the respect of his employees and the confidence of the public. Both pharmacy and business are constantly developing and this development brings changes in the knowledge required and the methods involved in business.

Practices which are modern today may be entirely out of date a few years hence. How often it is said of unsuccessful men: "He did not keep abreast of the times", or "He persisted in the old fashioned methods of doing business and the younger generation simply does not take to them". Continual study, both of the technical and business phases of pharmacy, is the price of success in this field just as it is in any other. The well-informed physician or chemist of ten years ago is technically ignorant today unless he has by hard study kept up with the rapid strides made in these professions in recent years. The same is true of the department store manager or the hardware storekeeper. Therefore

the head of every business and especially the manager of a pharmacy should make an earnest effort to keep informed on all developments in his field. To this end pharmaceutical and other related journals as well as an up-to-date library of books on the professional and the business side are indispensable. (see page 1625).

Division of Labor Essential—The proprietor or head of a business must learn very early in his career that time is valuable and must not be squandered on non-essential tasks. As soon as it is possible an organization should be built up which will relieve the proprietor of the details of conducting the store, that he may become, in every sense, a manager or directing head. The more time the proprietor spends in taking care of petty details the less time will be available for the proper planning and development of the business as a whole.

The management of a modern retail drug store, when analyzed, naturally divides into the following subdivisions: Buying, selling, stock-keeping, delivery, manufacturing, dispensing, bookkeeping, and supervision of departments such as soda fountain, cigars, sundries, confectionery, etc. In a very large store it may be possible to have heads for all of these subdivisions, or two or more divisions may be placed under a single head.

In smaller stores the proprietor may be required to assume all or most of the many duties theoretically assignable to various administrative heads but the sooner this situation is remedied the more certain will be the growth of the business. No one person can hope to function efficiently in all of these fields and in attempting such an impossible task a definite limit is immediately established for the business.

Occasionally some one takes pride in the seeming ability to handle all of the innumerable details involved in conducting these various departments but the result will be a failure to grow properly. A "one-man organization" is always dangerous, and if the one man should break down or leave, the entire machine would be disorganized, at least temporarily.

Even in the smallest business, the proprietor should begin to divide the duties by developing reliable helpers. The multiplication of personal ideas and capacity is unlimited if one will pay the price of *careful selection, systematic training, and adequate reward* for associates.

Perhaps the first step in seeking assistance beyond the usual help of a boy to run errands, is to get help in the accounting or bookkeeping requirements of the store. This is readily available for any store, by giving some trained bookkeeper in the neighborhood an extra job or by engaging a young woman assistant who will also be able to relieve the proprietor of other minor duties. Correct and understandable facts about finances are the very foundation of growth and prosperity. (See page 1269, also pages from 1391 to 1426.)

If there is a soda fountain in the store the proprietor should seek relief from its problems by placing the right man or girl in charge there, holding them strictly responsible for carrying out the proprietor's ideals of service and also for profitable management.

Gradually, as the business grows, each department may be organized with someone at its head who is immediately responsible to the proprietor or manager. In every case the department manager or managers should be encouraged to confer frequently with the proprietor or general manager on the various problems of the business, discussing with him personally the individual difficulties of the department and receiving from him encouragement and advice regarding new plans and methods for increasing the business.

Every subordinate, no matter how low in the scale he may be, should be impressed with the important relation of his task to the business as a whole.

After all, each employee is the representative of the head of the business in the particular task assigned to him and if this fact is properly emphasized he will not only be apt to perform his own duties better but his estimate of the job assigned to him will also be greater and he will take more interest in it.

Capital—In order to begin business one must have some capital, that is, sufficient money available for the initial investment in fixtures, stock, working capital, etc. Naturally, the first question asked is "How much will be required?"

The character of the store will in part determine this, since a small neighborhood store would of course necessitate a much smaller investment than a large, down-town business. However, the amount of capital may be determined in part by the estimated business. There must be a certain amount in fixtures and equipment, also in the initial stock and adequate working capital must not be forgotten or the business will be handicapped from the start.

The amount needed for fixtures is variable and depends upon the quality and also the size of the store, but the cost of stock usually bears a definite relationship to the sales and the efficiency of management.

An illustration of the figures of a modern business are given below as the basis for discussion.

Business Factors in Percentage

If an average sale per day is anticipated, amounting to	$100.00
The sales of a month would be, approximately	$3,000.00
Then with 100 per cent representing the sales	$3,000.00
And 66 2/3 per cent the "first cost" of goods	2,000.00
There would remain 33 1/3 per cent as "gross profit or margin."	$1,000.00

Out of this margin must come the "*overhead expense*" and "*net profit*".

The "overheads" are frequently classified theoretically as a basis for study as follows:

7 per cent—rent, heat, light	$210.00
12 per cent—Salaries (including that of the proprietor)	360.00
1 per cent—Advertising	30.00
5 per cent—All other expenses, (insurance, hauling, watchman, taxes, telephones, etc.)	150.00
Thus the 25 per cent expenses, or "overheads" equal	$750.00
This leaves 33 1/3–25 or 8 1/3 per cent as "net profit" or	250.00
The "overheads" and "net profit" together equal the "gross profit"	$1,000.00
Now if the "sales" per month were	$3,000.00
In twelve months they would be	36,000.00
The average "cost of goods" (at 66 2/3 per cent of sales) would be	$24,000.00

With this graphic picture of a business as an illustration, the amount of stock required for the assumed sales volume, would be dependent entirely upon the number of "turnovers" or "stock-turns". If the merchandise has been resold (or turned over) four times within the year, the capital would be one-fourth of the yearly cost of goods or $6000. If it is possible to increase the number of turnovers, the capital can be reduced proportionally.

A fair estimate of the capital required for an average business can be made on the following basis:

Stock (based upon 4 turnovers)	$6,000.00
Fixtures (including soda fountain)	5,000.00
Working capital	3,000.00
Total capital needed	$14,000.00

The reader should not infer, however, from these figures that at least $14,000.00 in cash capital is necessary to start a business of $100.00 a day. In actual practice, this might work out more like the following actual figures taken from a store that is operating successfully and that does an annual business of $42,000.00. The exact statement of this druggist is as follows:

Assets	
Cash	500.00
Inventories	8,000.00
Fixtures, fountain, cash register	5,500.00
Goodwill (actual cost)	4,000.00
	18,000.00
Liabilities	
Accounts payable (one month's purchases)	2,175.00
Notes payable (fountain fixtures and cash register)	4,150.00
Notes payable (goodwill)	3,000.00
Capital stock issued	6,000.00
Surplus	2,675.00
	18,000.00

The fixtures, fountain and cash register may be bought on terms that permit the capital to be increased as profits are earned. The goodwill of the business often may be purchased on the same basis. Occasionally a stock of merchandise is obtained on term payments.

The purchasing of merchandise on term payments, however, is apt to be very unprofitable for the retailer, because it ties him to one or two sources of supply and puts him at a great disadvantage in getting the best price and in earning cash discounts.

There is very little lost, however, by purchasing equipment on the term basis for the simple reason that it is only purchased once and the 5 per cent cash discount that is lost by purchasing standard unit fixtures for example, on a two year term basis, is more than offset by the 2 per cent monthly discounts on merchandise purchases that in twelve months would be 24 per cent and in twenty-four months would be 48 per cent. The fact that even the Pennsylvania Railroad and some of the great countries of the world buy railroad equipment and labor saving devices on a partial payment plan is assurance that the policy is sound, provided the equipment will perform a service commensurate with the investment.

It is apparent from the above example that this store was purchased and successfully operated on a cash capital of about $7500.00. As a matter of fact, $5000.00 of that $7500.00 was borrowed on long term notes financed by the family of the young druggist.

Many times drug businesses have been financed with as little as $2000.00 or $3000.00 cash, but this is an added risk and unless such a druggist possesses unusual ability and is fortunate in his location, he will be very apt to lose his investment.

An old store may exist on its reputation and goodwill but a new store is judged very quickly by appearances; unless it makes itself presentable from the start, it has little chance of competing successfully.

If an established store is purchased there will no doubt be a charge for "goodwill". By studying these figures a fair value for a store offered for sale may be estimated.

How to Procure Capital—*Individual ownership*—In some instances the prospective purchaser is already in possession of the necessary capital or may be able to procure it through his family. If the would-be proprietor has been

able to save a reasonable amount either through a saving fund, building and loan association, or a life insurance policy, it is usually considered an evidence of character and ability, and is of material assistance in securing further credit.

If capital is turned over to a young man by his father or by relatives without other obligation, it very often is received without appreciation and, only too frequently, proves to be a weakness in the foundations for success. When capital is supplied by the family or close friends, it should be accepted as a serious obligation, notes being signed, and interest paid, and these notes should be met with the same sense of honor and exactness which would be accorded any other business agreement.

A Partnership—A second method by which capital is sometimes procured is through a partnership agreement. Frequently someone with money to invest, is willing to place it in the business on a partnership basis, balancing it in part against the professional experience and training of the pharmacist. On the other hand, the partnership may be one in which every member of the firm equally contributes the capital and shares in the professional responsibility. The obligations of partners has been discussed under "Common Law", see page 1247, and should be thoroughly understood, and the agreement should be in writing, drawn up by a competent lawyer, before any business relations are assumed. This should hold true whether the partners are total strangers or the closest friends. One never knows what differences may arise in the conduct of a business and if there is a disagreement it is best for all concerned to have a proper legal status upon which to base a dissolution. A most important success factor in a partnership is an exact understanding of the duties and responsibilities of each partner. This should also be in writing.

Financing by Wholesale Firm—A third method for obtaining capital is to secure the financial assistance of a wholesale drug house. This was at one time a more common method of getting into business than it is today. The advantage to the wholesale house is that it obtains another outlet for merchandise, but the National Wholesale Druggists' Association in recent years has cautioned its members against multiplying store owners promiscuously, in this fashion. There are some disadvantages to both retailer and wholesaler in this plan. When a wholesale house or manufacturer supplies stocks on credit, to be paid through a series of notes, it practically amounts to a temporary partnership. Rather than lose his first investment with a retail druggist who does not make an immediate success of his business, the wholesaler may be tempted to extend further credit and he may be "throwing good money after bad". On the other hand, the retailer is in honor bound to practically limit his purchases to the wholesale house, which has extended credit, and this is not always desirable.

Corporation—A fourth method is to organize a company, incorporating and selling stock, or floating bonds in order to obtain the required funds. Large business ventures frequently raise the necessary capital by this means. The affairs of such an organization should be managed through a board of directors.

When this method is resorted to it is important for the pharmacist to arrange for a controlling interest in the concern so that he may be able to dictate its policy and insure his own future as a member of the firm.

Aid from Banks—Occasionally a well-known individual may be able to obtain some capital from banks on the strength of his personal reputation for business ability, honesty, and local popularity, but in such cases a close watch will be kept by the bankers on the progress of the business.

Capital is money which remains constantly employed in the business. Bank loans should be sought only for temporary or unusual needs, in which the

money may be returned to the bank after the circumstances demanding it have passed.

The retail druggist may reasonably expect two types of credit accommodation from his bank. The following example illustrates the first type. For his Christmas trade a druggist may want to buy in October an unusual quantity of imported novelties and paying cash for them at that time whereby he may obtain an unusual price concession. Past experience gives him every reason to believe that he can sell his purchase profitably during the holiday season. If he does not have the money to pay cash, he may go to the bank and ask them to advance it to him. Suppose the amount of his proposed order is $500 on on which he can obtain a 5 per cent discount by paying cash in October. He gives the banker a note for $500, due three months later, say January 15 (when the merchandise will have been sold). The banker gives him $492.50; the $7.50 deduction is 6 per cent interest for the three-month term of the note. By paying $7.50 interest for this loan, the druggist is able to save the $25 cash discount. The profit is apparent.

The other type of credit accommodation which the druggist may obtain from his bank is known as the improvement mortgage. For instance, a druggist may feel that by modernizing his building and equipment he can enhance greatly the value of his property and also increase his business. If his proposition looks practical, the bank may agree to finance for him a part of the cost of making the improvements. Suppose the cost of the improvements is estimated to be $3000. The bank may agree to advance $2000 of this. The first week that alterations are under way $300 worth of work may have been done. After this work has been inspected and approved by an officer of the bank, a payment is advanced by the bank to the extent of two-thirds of the cost of the work actually completed. Additional funds are advanced by the bank in like proportion as other parts of the work are completed. The amount advanced by a bank on an improvement mortgage is usually limited to 50 to 75 per cent of the cost of the improvements. Funds for the rest of the cost must be obtained from other sources. Sometimes the druggist uses his own money or the contractor may give him credit in exchange for a junior mortgage. Payment upon improvement mortgages is often made serially or the bank's mortgage may be funded later into a long term mortgage.

It is, of course, not the business of banks to lend capital. As a matter of fact, a bank is supposed to be able to recover on its assets within four months and if money were loaned for capital, it would not ordinarily be available for years. Many retailers seem to take offense because their banker has refused them a loan for working capital, but as a matter of fact the banker has no other choice. It might be mentioned that a banker is seldom interested in the physical appearance of the store, nor is he interested in the great stock of merchandise, nor in the prospects of the store. If a store is in a position to borrow money for seasonal business fluctuations, then all the banker is interested in seeing are the figures, for if based upon accurate records they are representative of the condition of the business.

Personal Credit—The pharmacist who goes into business faces, early in his career, the problems which relate to credit in one form or another. He soon finds it to be a fact that the underlying foundation of business is *confidence,* which is only another word for *credit.* For himself he must build up a credit which is based, first upon the actual property in his possession, either in the form of real estate or other marketable collateral; and secondly, upon his reputation for integrity and reliability. No business man is able to avoid a consideration of the relation of these factors to his business.

Commerical Agencies—Almost immediately after opening, the new pharmacist will be visited by a representative of one of the *commercial agencies*, such as Dun or Bradstreet, and will be asked to supply the necessary information concerning his financial standing so that a "rating" can be given him in order that merchants, with whom he attempts to do business, may be able to learn, through mercantile agencies, his worthiness of credit. It is desirable, therefore, that if an agent of one of these rating houses presents himself, the pharmacist should give without restraint all of the desired information, and above all make no false statements. The facts given are always verified as far as possible, and any deliberate attempt to falsify would seriously prejudice the securing of future credit. Willingness to give information of the type desired by credit agencies is interpreted as honest and straightforward dealing on the part of the business man. Hesitancy and foolish arrogance on the part of the retailer will do absolutely no good and may do a great deal of harm to his credit rating. These agencies have methods of securing the information desired anyway so it is the part of wisdom to let them get it directly and correctly in the first place.

It is desirable throughout all business relations to maintain the strictest guard over all matters which affect one's reputation concerning financial obligations. All money agreements should be promptly met, either by payment or by some satisfactory settlement.

Commercial Agency Form—A form indicating the type of information required by credit agencies is given below.

THE ———————— COMPANY

————————,..... 19

M.....

.....

We respectfully request that you furnish us a statement of your financial condition, on the within form, in such detail as you may elect, with a view to insure the correctness of our report. By so doing the chances of error will be lessened and confidence inspired in the minds of grantors of credit.

Those of whom you buy must get information regarding your responsibility, and employ The ———— Company to make the necessary investigation. That we may be better enabled to serve them and yourself is the sole object in making this request.

We ask such attention as the subject deserves.

Banking

It is difficult, one is almost tempted to say impossible, to conduct a business of even comparatively small proportions without the facilities of a bank. Therefore the pharmacist who goes into business should immediately establish proper banking relations. To many people a bank is merely a place for the safe keeping of money, and other valuables, but this is only one of its many functions. The payment of accounts by check, through a bank, simplifies and makes safe the handling of money and insures a receipt for the amount paid. Banks also offer other services to the business man, such as assisting him in establishing credit, loaning money to him in emergencies on proper security, providing a safe place for the storing of valuable papers, such as inventories, legal documents, etc., and performing other important functions.

Whether the institution with which the pharmacist affiliates is to be a national, state, or private bank, a trust company, or other form of banking house, will depend greatly upon the opportunities, convenience, and needs.

Opening a Bank Account—It must be recognized at once, that for satisfactory relations, confidence must exist between both banker and depositor.

It is presumed that before opening an account the business man has assured himself that the institution is sound and properly managed. This establishes confidence on the part of the depositor.

Before permitting the opening of an account the bank requires that the individual or corporation officers be introduced or that they in some way establish their identity. Then in an interview, usually with the cashier, the prospective depositor is invited to state the nature of the service desired from the bank and information is given regarding the regulations established by the bank, with reference to balance required, interest rate, etc.

To be frank and absolutely truthful is the only policy to be followed in making these arrangements. It is folly for a business man to hide his financial condition from a banking institution from which he expects service. Plans, prospects, and financial conditions should be frankly explained and an endeavor made to inspire confidence in one's integrity and ability. Any deception is certain to be discovered, and credit will suffer, probably irreparably. Of course it should be understood that a bank is just as much a business institution as a retail store and the banker does not confer a special favor by accepting an account; that is the business of the bank. However, banks are usually so well regulated both by law and good management that it is common to consider the risk in the business relation between a bank and a business as being greater on the part of the bank. That naturally places the bank in a position of advantage when banker and business man get together. When a business has developed beyond a certain point it frequently happens that banks are desirous of obtaining its account and make special efforts to do so.

Signature—When the bank is satisfied that it is dealing with someone of good standing, and mutually agreeable arrangements have been made, the depositor is asked to enter his name in the form thereafter to be used on checks and other formal documents. This is done for mutual protection, since the only evidence which the bank will have that a check is genuine, when called upon to pay it, will be the similarity of the signature on the check with the one on record at the bank.

Making Deposits—The depositor is given a *bank book* sometimes called a *pass book*, in which the "receiving teller" at the bank will record the deposits that are entered to the credit of the account.

In making out deposit slips classify the deposit as indicated on the blank, entering all checks singly and indicating the name of the bank upon which the check is drawn or writing in the number assigned to the bank, which will be found printed on checks. This slip, with the properly endorsed checks and any cash to be deposited, are presented with the bank book at the receiving teller's window.

The bank book is retained by the depositor and is only returned to the bank at intervals for balancing; *i. e.*, the entering of the total drawn out and a statement of the balance remaining to his credit. Many banks today issue to their customers a monthly statement giving a complete list of deposits, checks drawn, and the bank balance. This is of great help to the customer and should be requested.

The Check Book—Banks provide check books for their customers and when the account is a large one, specially bound books are provided with checks arranged for convenience of signature, etc. The name of the individual or firm running the account may also be printed on the check. When an order is drawn on a bank to pay a stated sum of money to a third party (called drawing a check) there should always be a record on the permanent stub, of the essential facts regarding the check. This will include a duplicate

number, the date, the name of the party in whose favor the check was drawn, the amount to be paid, and any additional explanation of the purpose or reason for payment. Brief but full notes of explanation on the stub will prove of great value in keeping accurate accounts.

In drawing the checks one should see that they are numbered consecutively in order to facilitate reference to the notes on the stub, and for verifying the records when the checks are returned by the bank after payment. Arrangements can be made to have numbers printed in series on the checks.

The date should be the current one unless that be a holiday or a Sunday. To date checks ahead, called *post dating*, is objected to by the banks, and unless there is a very good reason it should be avoided.

The name of the party for whom the check is drawn should be clearly written, and all blank space left should be filled in by a line. Usually the check is printed with the words *or order* following the name, to permit the receiver of the check to order its payment to another party, if desired.

The amount of money for which the check is drawn is indicated by numerals, and also written out, and, should there be any discrepancy between the two amounts the written figures are usually accepted.

Here again any space left is filled in by a line where the amount is written, and the numerals should be placed close to the dollar sign ($), to prevent *raising*, or the increasing of the amount, by adding to the figure originally written. Many expedients have been offered to prevent the "raising" of checks. Some of these protective measures consist in the use of paper which will be changed in color if chemicals are applied to alter the figures. Others use paper covered with fine lines, which would be destroyed if scratched. Most commonly the area where the numerals are written is afterwards finely perforated and inked in such a way that tampering with a check would easily be detected, while others cut out the amount from the paper with a special machine or else stamp the sum across the check with a machine which cuts the surface of the letters and introduces indelible ink at the same time. Writing the amount in "India" ink is another safeguard sometimes practiced.

The signature should be that adopted and registered at the bank and should be consistently uniform and legible.

Endorsement—When a check is drawn to the order of an individual or firm, it must be endorsed before it will be accepted on deposit or cashed. Endorsement consists in writing the name on the back of the check exactly as it is written on the face of the check. The endorsement should be written on the end which corresponds to the left hand side when reading the check.

When the name has been wrongly written or misspelled on the face of the check, it should be endorsed similarly, but followed with the correct signature.

When it is desirable to limit the use of a check, when endorsed, the signature should be preceded by the words, "Pay to the order of————". If for deposit, write "For deposit" and then endorse.

If the payee only signs as endorser, without any restriction as to payment it is called "signing in blank" and should the check fall into the hands of a third party for whom it was not intended it is negotiable and can be cashed. It is always best to use the "restricted endorsement" introducing the words "Pay to the order of———".

Voucher Checks—A check when returned through the bank, is one of the best forms of receipt, as it requires the signature of the party in whose name it was drawn, and this is evidence that the money was received.

It is often difficult, however, to prove that the money was in payment

of a specific indebtedness, and to obviate this the "voucher check" has been introduced.

This form specifically states that the check is drawn in payment of a certain debt, which is mentioned, and that endorsement will be an evidence that the obligation is fully satisfied and no further receipt is needed.

The voucher check is frequently a special printed form and sometimes the bank will supply these without additional cost but, if this is not practicable, the ordinary check may serve the purpose of a voucher check, if a rubber stamp is provided and used on the back, immediately above the place for endorsement. This stamp should read as follows: "Endorsement of this check is evidence of full payment of the following": Below the stamp can be entered the dates of invoices or a brief description of the obligation which is being paid.

Other Types of Financial Paper—In the chapters devoted to Commercial Law (see pages 1245 to 1249), there is a discussion of financial paper from a legal standpoint, but in connection with banking it is well to call attention here to a few of the more important papers which are commonly associated with business enterprises.

Promissory Notes are frequently given in settlement for goods purchased with the object of securing prompt payment at a specified time. There is a definite legal form for such notes, which may be given as security for money borrowed or in settlement of an account to fix the amount of the balance agreed upon and a time for paying it.

Drafts are sometimes employed as means of collecting debts. A draft consists of an order drawn by the creditor on the debtor directing the debtor to pay a certain sum of money to a third party. While similar to checks in some respects the form and wording of drafts differ from those of checks and whereas a bank is bound to pay a check when properly drawn and presented, if the funds are on deposit, it is not compulsory for the merchant to honor a draft if he does not choose to do so. Of course, failing to honor a draft may influence credit adversely.

Trade acceptances and *bank acceptances* are being used extensively in paying accounts spread over a period of several months in which either a bank or a business organization are the endorsers. By means of acceptances it is possible for a business man to purchase quantities of merchandise on a time basis making regular payments at intervals through acceptances, previously filed with the bank or creditor, until the bill for the goods has been met.

The Bank—Safety is the prime requirement which everyone expects of a bank and this should be insisted upon before selecting a depository. Fortunately in the United States, a banking system has been developed through the aid of the National Government, which insures a maximum of safety and service and, with the more recent development including the Federal Reserve banks as a part of the system, elasticity has been given to the currency and many new functions have been provided, while previous defects have been eliminated.

National Banks—The first type of bank, therefore, to be considered is the *national bank*. This is established through a written application to the Comptroller of the Currency in which is stated the desired title, the location, the amount of capital to be provided and the names of at least five persons who propose to become stockholders.

At least 50 per cent of the capital must have been paid in before the organization is perfected and the balance must be paid in monthly installments of 10 per cent each, dating from the opening of the bank. In other words, there must be an approved location, where there is a real necessity for a bank,

and the capital must be all paid in within a stated period. The amount of capital is definitely fixed by the Banking Act—$25,000 is the minimum in towns not exceeding 3000 people,—$50,000 in places not in excess of 6000 people—$100,000 where the population does not exceed 50,000, and $200,000 in cities of over 50,000. The directors of the bank must own at least ten shares of the stock, which must remain free from any obligation, such as use for collateral. The director must also be a citizen of the United States.

A national bank may own its own building but that must be used exclusively for banking purposes. The bank is not permitted, however, to hold other real estate, excepting temporarily when taken over as security for an obligation to the bank. A national bank may perform the following banking functions:

(1) Discount promissory notes, (2) receive deposits, (3) buy and sell exchanges, coin, and bullion, (4) loan money on personal security or other satisfactory collateral, (5) loan on the security of farm land and on improved or unimproved real estate, (6) issue circulated bank notes, (7) act as trustee, executor, administrator, receiver, registrar of stocks and bonds, or may perform any of the routine banking functions permitted state banks and trust companies, (8) a national bank may act as agent for insurance companies or as the broker in negotiating loans on real estate but this last function may be performed only in towns of less than 5000 people, (9) they may accept drafts or bills of exchange, and (10) may establish branches, either in this country or abroad.

Loans may not be made to any individual or group of individuals for more than ten per cent of the capital and surplus of the bank. There are other restrictions on loans, such as that they must be for a comparatively short time, not more than three or four months. A national bank may not overcertify checks.

National banks are permitted to issue bank notes but these must be secured by a deposit of United States Government Bonds which are held in the United States Treasury. These bank notes circulate as currency throughout the country. This privilege is not granted to any bank other than the Federal Reserve Banks.

A national bank may not make contributions toward a political campaign. It may not loan trust funds to directors. There are also other minor restrictions which tend toward increasing safety. One reason why a national bank is considered especially trustworthy is the responsibility assumed by the shareholders. In case of insolvency, not only will a shareholder lose the value of the stock owned, but will be also responsible personally, if called upon, for an amount equal to the par value of his stock.

A regular and important feature of the National Banking System is an examination by representatives of the Comptroller of Currency. These examiners must visit the bank, inspect all books of accounts, securities, and assets, as well as liabilities, and may demand information from any officer concerning the condition of the bank. The examinations may be as frequent as is thought necessary and are without notice. All expenses, however, must be paid by the bank.

The establishment of the Federal Reserve System in 1913 greatly enlarged the functions and influence of the National Banking System. Every national bank was required to subscribe to the Federal Bank stock an amount equal to 6 per cent of its paid-up capital and surplus. In other words, the Federal Reserve Banks serve in the same relation to member banks as the individual national bank serves its depositors and stockholders.

When a National Bank is in need of further currency to loan to customers, a Federal Reserve Bank will discount the collateral already held by the National Bank, thus providing it with additional currency for re-loaning. A Federal Reserve Bank also establishes the rate of discount, preventing excessive charges which in times of money stringency had always been one of the serious defects of the old system.

The Federal Reserve Banks also issue bank notes, a privilege originally granted only to the National Banks.

The functions of the Federal Bank are as follows: (1) To discount the endorsed paper of member banks, maturing within ninety days if the proceeds are to be used for commercial purposes. If the proceeds are to be used for agriculture or livestock, it may be nine-month paper. (2) To discount acceptances upon imported or exported goods if they carry shipping documents or warehouse receipts, such paper to be endorsed by a member bank, and to be due within six months. (3) To deal in cable transfers, banker's acceptances, and bills of exchange. (4) To deal in coin or bullion. (5) To establish rates of discount, and (6) to make advances to member banks on their notes, when secured by approved collateral. The entire Federal Banking System is under the management of the Federal Reserve Board of eight members, who are the Secretary of the Treasury, the Comptroller of the Currency, and six others appointed by the President of the United States. Federal Reserve Banks have been established in some of the larger cities throughout the country and are geographically distributed so that all parts of the country may be adequately served.

The Clearing House—An important part of the National Banking System is the clearing house. This is an association of national banks and such other banking institutions as subscribe to the regulations. The clearing house is for the purpose of exchanging drafts and checks and settling the balances between the member banks. It furthermore serves to promote the general welfare of all of the banks in the organization.

A clearing house is established in every banking center and, on every business day, representatives of each bank present themselves at a stated hour, usually ten o'clock, a desk being provided for each. A clerk of each bank remains at the desk to which the bank has been assigned, and the second clerk moves from desk to desk with the packages of paid checks, made up for each member bank. The envelope of checks carries a statement of the amount involved and a receipt is given upon delivery at each desk. When every clerk has systematically presented the package of checks to all banks involved, the totals are quickly made up and a check drawn for the difference by either the bank representative, if there is a debit, or by the clearing house clerk if there is a credit. In this way the accounts of every bank with every other bank are quickly balanced and settled every day. Smaller banks in outlying districts, which cannot send personal representatives, arrange for one of the city banks to "clear" their checks.

The benefits of the clearing house are evident. The expense of collecting on checks is greatly reduced. The use of actual money in settling between banks is not required. Should a member bank meet with temporary misfortune, though fundamentally sound, the other member banks will come to its assistance.

In time of panic, the clearing house also provides opportunity for united action, even to the extent of issuing clearing house certificates in lieu of cash, should that become necessary. The clearing house also keeps all banks up to a high degree of efficiency.

Other Banking Institutions—A number of other financial institutions have been organized under State laws, and are well established in many places. The most important among these are the so-called *trust companies*. They originally possessed some advantages over National Banks, being permitted to act as trustee, administrator, etc., of stock, but the Federal Reserve Act has broadened the functions and privileges of the National Bank so that it may now perform many of the same services.

Trust Companies—A trust company receives its name from the service which it renders corporations through acting as the trustee of the collateral upon which bond issues were secured, and guaranteeing to the purchaser of bonds a proper record upon the books of the company. The trust companies also very largely assume the obligation of trusteeship or executorship for estates, especially in taking charge of affairs of minors.

Another function of trust companies in many localities is that of guaranteeing the title of property. This is referred to on page 1288. Trust companies usually pay a small rate of interest even upon deposits subject to check. As a rule, this is not more than 2 per cent.

State Banks—Another form of bank is the State Bank, organized under the laws of the State in which it is located. It is subject to supervision by the State banking department only. The general business conducted is similar to that already described, excepting that the banks are not permitted to issue notes. This function, prior to the establishment of the National Banks, was a common custom for State Banks; but in 1863, when the National Banks were established, a 10 per cent tax was placed upon circulating notes of State Banks and this is prohibitive.

The importance of this is readily understood, since the issuance of notes must of necessity carry confidence and reliability and the old bank notes were frequently found to be valueless.

Savings Banks—These banks occupy another field among financial institutions. Small amounts are accepted for deposit and the depositor cannot withdraw money by check but must give two weeks notice. Savings banks are mutual, that is, profits are shared by the depositors since the assets are entirely their property, there being no stockholders. Because of their character, the State banking laws rigidly control the kind of investments permitted. Safety rather than large return is the primary consideration. As a rule, the only types of investment permitted are loans on approved collateral, investment in government, state, or municipal bonds, and loans on approved first mortgages.

The object of savings banks is to cultivate thrift and provide safety and interest for the small as well as the larger depositors. As a rule, a saving fund does not pay more than 3.65 per cent interest.

Private Banks—This is still another form of bank which is an important factor in financial circles. Such an institution is dependent only upon the financial standing and credit of the owners. Such banks have at times performed very important services, especially in international affairs, as they are free to give help which may involve large risks but which may be of very great merit. Private banks also frequently serve an important function in stock market transactions through over-certifying for those in whom they have confidence. Such houses as Drexel and Company, Philadelphia, J. P. Morgan and Company, of New York, and the Rothschilds, of Europe, are illustrative of firms of this character which have become internationally known.

Postal Saving Banks—The small private banks in the foreign sections of large American cities, are usually conducted by one or a group of the foreigners

themselves. They do not, as a rule, offer very satisfactory security. Largely for this class of citizens, the Government has established a postal saving system which permits the individual to deposit any amount, from 10 cents up, at any post office. As evidence of the deposit, stamps are issued for amounts less than $1.00, and postal saving certificates for $1.00 or more. Two per cent interest is allowed if the money remains on deposit for a full year.

The depositor may withdraw his money at any time by presenting his stamps or certificates to the proper officer at the post office or payment may be made by mail upon request. In this way, safety and confidence are provided for those who may not be in a position to open an account in a regular bank.

Building and Loan Association—A consideration of financial institutions would not be complete without briefly discussing building and loan associations. These organizations are always established for local benefits and were started in Philadelphia in 1831. The primary object is to enable the members to become owners of their own homes. They also serve to stimulate saving. The association issues shares, usually of $200.00 each, the members paying monthly installments at the rate of $1.00 for each share, until the accumulation of dues and the interest on investment has created a value of $200.00 for each share when the amount is paid over to the shareholder. Frequently the building and loan association will advance money, on first mortgage, to the shareholder who then pays the monthly dues and also six per cent interest on the loan, in monthly installments and, usually, in addition, a small premium. In this way, month by month, an amount is paid which is generally less than would have to be paid for rent, but which within from eleven to twelve years builds up a surplus which insures the ownership of the property.

Building and loan associations are subject to very exacting state regulation and inspection, and, with a few exceptions, have been of great benefit to the shareholders, providing perhaps the largest return on investment available to the average individual.

Insurance

The head of a business, being responsible for its welfare, seeks to protect it against all possible losses such as those from fire, accidents, death, or illness of important officers, errors, or other unavoidable factors. To guard against such financial losses he may take advantage of the various types of insurance now available.

Insurance in its various places has been one of the developments of modern business. It involves the principle of a number of individuals uniting to share a possible loss, each paying a small percentage but receiving the protection agreed upon in a written document known as the "policy". This document should be carefully drawn and should enumerate all of the conditions and agreements.

Insurance companies may be stock companies in which the profits are divided among a limited number who hold stock, or the company may be "mutual", in which case all policyholders share in the profits, through a reduction in rates or the distribution of a "surplus".

Insurance companies are controlled in their business methods and in the character of their risks by state or federal laws and are subject to regular governmental inspection.

The rate to be charged, known as the "premium", is determined through years of experience and varies according to the conditions. When the risk increases, due to a greater fire hazard in case of fire insurance, or when an

individual is no longer young and the expectancy of life is less, as in the case of life insurance, then the premium is larger.

The first essential in considering insurance is the selection of a reliable company. In taking out insurance, it is usually preferable to insure through a local agent. This has the advantage of securing personal interest in the protection purchased, through the desire of the agent to give service and acquire a good reputation and more business, and also in case of loss it will be a matter of personal pride with the agent and good business for him to make satisfactory and prompt adjustments.

The principle of insurance is today applied to any condition which may involve a risk. There are insurance companies which will insure any individual against any loss which might occur. The most important applications of insurance are protection against loss by fire, against marine disaster, against accident, injury, or sickness, or it may be liability insurance, which covers responsibility for injury to someone else, or perhaps life insurance, or burglary or plate glass insurance, or title insurance for property, or any other of lesser importance, such as tornado, steam boiler, property damage, parcel post, weather, etc., etc.

Considering the more important of these individually, fire insurance probably should come first.

Fire Insurance—The first consideration is the amount for which to insure. Naturally the policy should not be taken out for more than the property is worth. In case of fire, strict inventorying of all losses and the proof of the loss will have to be provided before the amount of the policy is paid. Fundamental honesty is a basic requirement. It is always wise to keep a copy of a recent inventory of the store in a safe deposit box outside of the place of business.

Re-insurance—Re-insurance is a practice common among insurance companies whereby they share risks in any one locality. Should one insurance company write a large fire insurance policy for an industrial plant or many individual fire insurance policies in one community, rather than risk the possibility of a large loss in case of fire, the company will re-insure these risks in a number of other companies. This is also true of marine insurance, one company writing the policy for a ship and then dividing it among many other companies.

The Eighty per cent Clause—Having determined the value of the property to be protected, the policy should then be drawn for at least 80 per cent of the value. What is known as an 80 per cent clause, is a feature of practically every fire insurance policy. This means that unless the owner is insured up to within 80 per cent of the possible loss, he becomes a *co-insurer* and shares in the loss. The equity in this is evident, since it might otherwise be possible for a $100,000 plant to be protected by a $10,000 policy on the assumption that there was not likely to be more than a $10,000 loss at any one time.

If this were done, however, with the 80 per cent clause in operation and a fire occurred, the owner of the property would receive only one-tenth of the loss, it being recognized that he had assumed nine-tenths of the risk.

The Rider—An insurance policy always carries a rider which is a typewritten form attached to the standard policy, setting forth the specific conditions applying to the property insured. There should be permission to make repairs, to close the store or property for a limited time, that is, months or weeks during the year, to use electric lights or other form of lights, if necessary. It should also carry the standard clause, protecting the property against fire by lightning, and should permit the use of gasoline or oil stoves, if this is necessary, or any other special privilege desired. (See page 1397 for a typical policy.)

Assignment of Insurance—If the property is mortgaged, the insurance policy is assigned to the owner of the mortgage through a special form.

In Case of Fire—In case of fire, all reasonable means must be taken to prevent further loss, such as might occur through theft or breakage. Notice should be given immediately to the insurance company, setting forth all of the facts. Usually the company retains the privilege of re-building if it desires to do so, and most insurance policies include the right to pay the loss within six months, but, as a matter of fact, good companies make every effort to pay promptly as it places them in good repute and stimulates more business.

An inventory of fixtures and stock will be discussed elsewhere, but its importance in the adjustment of a fire claim cannot be overestimated, since an evidence of loss must be produced for the settlement of a claim. If a recent inventory is available, the adjustment is simple and if the inventory is arranged according to sections of the store a claim can be readily substantiated, even should only a partial loss occur.

Life Insurance—If an individual has assumed grave responsibilities, either for entrance into business or involving the duties toward a family, and if there is not ample reserve capital available, the taking out of life insurance becomes an imperative duty. Fundamentally, life insurance is only for the use of beneficiaries, although policies are being written today which provide protective features for the person insured, such as income for life in case the insured is incapacitated by accident or sickness, or when the policy becomes "paid up" and is then operative at a certain age. If the individual has no large obligation and no one who is dependent upon his support, then life insurance is not considered so desirable a form of investment, as larger returns can be secured from many other safe investments.

Forms of Policies—Policies are written in many forms. The *ordinary life policy* requires a relatively low premium, since it pays only for the estimated cost of carrying a policy. A *limited payment life* policy is one in which the premiums are paid for a fixed number of years when the policy becomes "paid up". This form of policy is only paid to the beneficiaries after death.

Another form of life insurance, commonly written, is known as an *endowment policy*. The premium in this case is larger, since the policy guarantees the return of a fixed amount to the insured at the termination of an agreed period, usually ten or twenty years. The cost of the policy must cover the risk, plus the principal, which accumulates. A *joint life policy* is one which insures two or more lives, the amount to be paid to the survivor or survivors. It is especially applicable to partnerships and is intended to cover the loss of capital or service incurred in case of death.

A limited term policy is one in which the amount of premium is fixed for definite periods, say five or ten years and is the cheapest form of life insurance. Should the period terminate and the insurance be renewed, it must be at a higher rate, based upon the age and conditions. This policy may usually be converted at any time into other forms.

An annuity policy is one which insures the payment of fixed sums of money after a stated period of years, or at death. This policy is of particular value in the protection of a family, for it guarantees definite income for a number of years, without the probability of loss. Frequently insurance policies are paid to the beneficiaries who invest the money thus acquired unwisely and the policy thus fails to perform the purpose for which it was intended. Annuity policies avoid such a contingency.

All life insurance rates are determined through what are known as *mortality records*, assembled over many years, from all civilized countries. This has

established an average *expectancy of life* and all life insurance companies use this as a basis for their rates.

Insurance policies which involve the endowment or annuity features possess a cash value which may be obtained at any time should the insurance policy be canceled, or which may be used as collateral for the securing of a loan. The person taking out insurance may direct the payment of the benefits accruing from the policy to any individual named. This person is termed the *beneficiary*. This, of course, is usually a near relative or some individual or interest to be benefited.

There is no limit to the amount of insurance that may be placed on the life of an individual, except the passing of the physical tests and the possession of the ability to pay the premiums on the policy.

Accident and Health Insurance—This form of insurance is being extensively carried by those who are dependent upon an income from their service. It usually covers a weekly allowance in case of illness, and frequently includes the cost of hospital and operative charges in case these should be required. The policy establishes a fixed amount for the loss of an eye, an arm, etc., or in case of death by accident. A policy of this character should be very carefully scrutinized to be certain that it does not include special clauses, which may render it of no value when most needed, for instance, illness from tuberculosis may exclude the policy holder from the benefits.

Burglary or Theft Insurance—This form of insurance gives a double protection. Not only is there remuneration in case of theft, but the company always provides a plate to be attached to the property, in a prominent place, and the robber knows that when property is so protected there will be special efforts made to apprehend the thief, through the employment of skilled detectives. There is usually some hesitation therefore to burglarize the property.

Plate Glass Insurance—The retail drug store is particularly in need of plate glass insurance. This may be written to cover the plate glass windows, also the glass-shelving, case-tops, etc. The windows are particularly prone to meet with accident from the outside.

Title Insurance—In many states the guaranteeing of the title of property by a special company which writes title insurance, is a requirement in case of mortgage. In fact, anyone buying property should make it an "iron-clad rule" to insist upon receiving, with the bill of sale, a guarantee of the title. This necessitates the company making a "search" of the property, and unless this is done there is always danger of some other obligation, such as back taxes, or mortgage, or lien, becoming a prior claim, thus rendering the sale and title of no value.

Liability Insurance—This form of insurance, as it applies to the retail drug store or other professional service, is of special importance. Accidents may occur in any drug store or professional service may be the subject of blackmail. Liability insurance provides competent defense in the form of skilled lawyers. It covers the consequence of prescription errors, mistakes in delivery, and poison accidents. It does not, however, lessen the necessity for the utmost care on the part of the insured. It gives no permission to be careless for the ultimate defense must depend upon there being no *contributory negligence*. This means that the person insured must comply with every regulation of the law in the conduct of his business. The proprietor of the store and the individual clerks must be separately named in the policy. Liability insurance is also carried or should be carried by every person who drives an automobile. Accidents are frequently unavoidable and the driver may be held liable for large damages.

Workmen's Compensation Insurance—This insurance is a requirement of the law of many states. It guarantees the employee, in case of accidents, certain specified payments in lieu of wages. The amount is determined by the amount of wage earned. The minimum premium in Pennsylvania for this compensation insurance is 19 cents per $100.00, thus a $19.00 annual premium would cover an annual payroll of $10,000.

Fidelity Insurance—Many firms, especially corporations, require that all employees be bonded. This means that the employee must provide necessary information concerning his character and financial standing. Individuals named as references are asked to express their personal judgment concerning the character and worthiness of the insured. This form of policy has the advantage of protecting the firm or corporation against loss through theft or embezzlement, but its most potent force is in its influence upon the individual who knows that in case of misdemeanor he would be compelled to face a cold-blooded tribunal that would give no consideration to any personal friendship.

All of the foregoing types of insurance apply to the drug business, or the executives of a business. Most of them also apply to other types of retail business. Insurance should be looked upon as protective and wherever there are risks the management of a business should study the possibilities of covering them adequately. Many a reputable pharmacist has been the victim of blackmail in the matter of alleged errors in prescriptions, and has had to pay tribute to protect his good name and avoid harmful publicity, when a small sum, paid annually, would have afforded him protection through an insurance company ready to take his case to court and frustrate the scheming blackmailer.

Income Tax

The owner or managing director of a business is now responsible to the United States Government for an annual statement of receipts and expenditures in the form of an income tax statement.

The establishment of an income tax by the United States Government, while looked upon with disfavor by many, has been one of the potential influences for success in American business through its development of correct accounting methods. It has oftentimes made it possible for a concern to discover serious losses and greatly increase its efficiency of organization and management.

An income tax report is required by the United States Government from those individuals or firms receiving annually the amount of income specified in the Act which is in force at the time of making the report. The minimum amount has been so frequently altered by acts of Congress that this detail should be procured through the local collector of Internal Revenue. Exemptions are provided which become greater if the individual is married and if there are children. When the income exceeds a specified amount, the rate of tax increases.

The first essential in the making up of an income tax report, which is required every year, is that there be proper financial record of all transactions. If this is available, there is little difficulty in making up the report. Almost every bank offers expert advice to its customers in the preparation of these reports and the Collector of Internal Revenue in each district is also prepared to give information. In making up an income tax report, care should be taken to include among the deductions, all expense connected with professional service. For instance, a physician may deduct the cost of upkeep for the automobile used in visiting patients. If this automobile is also used for pleasure, an adjustment must be made.

Another important deduction frequently ignored in making up an income tax report, is that of deterioration on property and fixtures. In the case of fixtures, this is usually one-tenth of their replaceable cost on the assumption that new fixtures will be required within ten years. Income tax blanks may be procured from the local Collector of Internal Revenue.

It is just as important not to include the items that are unnecessary in the report as it is to include those which are required. The Government demands correct returns.

In the Chapter on Accounting, page 1391, there will be found a system of keeping business records which will show the exact financial status of the retailer from week to week, from month to month, or from year to year. These records will provide the facts needed for making out the income tax record required by the Government.

In general, the data which a small business man needs to have at hand for calculating his income tax are gross sales, purchases of the year, inventories at the beginning and end of the year, and the selling expense. The following information issued by the Internal Revenue Bureau is of value in this connection:

"The gross sales over the counter are known to every progressive store or shopkeeper. In many cases he has his cash register memoranda. Even if he has no register, he usually has some other records of his intake.

"Aside from cash sales, most small stores have running accounts with customers. In the case of a new business, it is important that accounts receivable for goods or services furnished during the taxable year are added to the cash receipts, the result to be taken as the gross sales of the year.

"In the case of a long established business in which the balances due from customers will average about the same amount each year, the storekeeper has the privilege of figuring his net income on a 'cash basis'. That is, by ignoring the balances due him from customers and including in his cash receipts the total of intake, regardless of when his goods were sold, he will arrive at an acceptable computation of the net result of the year's transactions.

"In any case where both the cash intake and the accounts receivable created during the year are taken into consideration as the gross sales, the storekeeper should guard against duplication of the same income by omitting the payments received on back accounts that were taken up in prior years as accrued income.

"There are, therefore, two methods of arriving at gross sales for the year. On the one hand is the 'cash basis', which is more practical for a long established store, and on the other hand is the 'accrual basis', which is more accurate from an accounting standpoint as showing the correct earnings of the store during the year.

"The purchases of goods and supplies during the year are obtainable from the inward invoices, which most shopkeepers retain for their own use in fixing retail prices. Invoices of goods not received at the end of the year should be included, and in these cases such goods must be included in the inventory for the end of the year; for, although in transit, the title to the goods has passed to the shopkeeper and they are considered as on hand. Goods or local products received in exchange for other goods should not be included; neither should cash purchases be considered if the intake for the year is figured on the basis of the daily gain shown in the cash drawer.

"The construction of inventories of goods on hand unsold at the beginning and at the end of the year is not a difficult matter in small merchandising. The stock on hand is generally well known to the owner, who, if he is wide

awake, keeps an eagle eye on his shelves and storehouse. The pricing of this stock is the thing that he must be most careful about, particularly in these years of fluctuating costs. The pricing should be by one of two methods: (1) Cost of each item or, (2) cost or market whichever is lower on each item. In either case he cannot value the stock at any price higher than cost, and by the second method the shopkeeper may use market price if it is lower than his actual purchase price, on any or all items.

"In pricing inventories there is another important rule of the Government to be observed; that is where goods are so intermingled that they cannot be identified with specific invoices they are deemed to be the most recently purchased, and the latest invoice prices on those particular items should be used.

"As to selling expenses, these are easily figured, for a shopkeeper keeps a close watch on his till and knows what it has cost to pay his help, to light and heat his store, to pay his rent, and to maintain his delivery service. Then there is the telephone, telegraph, postage, expressage, freight and repairs. He is also allowed to include *interest paid on borrowed money*, taxes on his business property, and a reasonable allowance for wear and tear on his fixtures, wagons, horses, delivery auto, or any machinery or other equipment which he owns and uses in the business.

"With the above data at hand, any small dealer may make the same computation as his big-town fellow merchant to figure the net income of the business. The procedure is as follows:

"Add the inventory for the beginning of the year to the purchases for the year; from this sum subtract the inventory for the end of the year, and the balance is the cost of goods sold. Taking this cost from the gross sales for the year he reaches a figure which is his gross operating profit for the year. From this gross profit he is allowed to deduct his selling expenses. The result is *net profit*, to which he should add any interest or other business income not included in his gross sales, and the result will be the amount which he will consider as his business net income.

"By pursuing the above method the shopkeeper eliminates consideration of his own salary or withdrawals from the business. If he made withdrawals from the business, whether daily, weekly, monthly, annually, or irregularly, in the form of cash or in goods for his home consumption, this amount must either be added back into the net income as computed by the method explained above or he should consider it as a salary withdrawn, and therefore taxable income. The point to be borne in mind is that Mr. Storekeeper is taxable on his entire net income, whether withdrawn or not.

"A merchant may have withdrawn a considerable amount of money from his business and yet have actually suffered a net loss in his year's transactions, his shelves having been depleted of their stocks. On the other hand, a million merchants are building up and extending their business, withdrawing only enough for living expenses. Their goods for sale, piled up at high purchase prices, may contain a goodly income earned during the year in the business done over the counter. Whether the earnings are put back into goods or are placed in the bank, or whether they are used to maintain the shopkeeper and his family or withdrawn by him for other purposes, the net result of the year's business must be identified and considered in its entirety when the income tax season arrives.

"It is also pointed out by the Internal Revenue Bureau that if the shop or store is operated by a partnership a return must be made on Form 1065, regardless of the amount of its net income. A partner must consider as

income his share of the net profits, whether distributed to him or not, together with his other taxable income.

"If the store is incorporated a return must be made annually on Form 1120, regardless of the amount of its net income.

"If operated by one proprietor he must consider the net income of the store, together with all of his taxable income from other sources, in determining whether a return is required. And, if he must file a return, Form 1040 or 1040-A should be prepared with due care and accuracy and filed on or before March 15th.

"In addition to the above returns there is another return required if any employee, landlord, mortgagee, or other person, or any fiduciary or partnership was paid in wages, salary, commission, bonus, rent, interest, or other determinable income, a total amount of $1500 or over during the year. Forms 1099 and 1096 are furnished for this purpose."

Legal Responsibility

In another chapter of this volume (see Part VII) will be found a discussion of the laws governing the practice of pharmacy. From a business standpoint it behooves the store owner or manager to keep in constant touch with the development in the laws and regulations governing the conduct of the drug business, for it is an axiom that ignorance of the law excuses no man if he becomes a violator. Federal, state, county and municipal laws, ordinances, rules, and regulations with respect to property, responsibility and restrictions must be lived up to and the head of a business should see to it that his employees are familiar with the legal limitations of their rights and privileges and their legal responsibilities to the business and to the public. The proprietor is in most instances legally responsible for the acts of his employees performed in the discharge of their regular duties, so it is a case of self-preservation to instruct employees in the laws governing their acts.

Briefly, the laws which affect the practice of pharmacy are as follows:

Federal Laws	State and Local Laws
Food and Drugs Act	Food and Drugs Act
Narcotic (Harrison) Act	Pharmacy Act
Prohibition (Volstead) Act	Narcotic Act
Patent and Trademark Laws	Prohibition Act
Insecticide Act	Trademark Laws
Anti-trust (Sherman) and other acts governing conduct of business enterprises	Insecticide and Fungicide Laws
Tax Laws (including income and revenue measures)	Advertising Laws
	Sanitation Laws
	Employees Liability Acts
	Miscellaneous Laws and Ordinances covering business transactions

The best method of keeping posted on the legal restrictions surrounding the drug business is to become a member of national, state, and local pharmaceutical associations which keep the members informed of proposed legislation as well as that which is enacted. In these days of great multiplicity of bills presented to state legislatures for enactment, it is very important for pharmacists to enter their protest against proposed legislation which would work a hardship on the public as well as the pharmacist. Many well-meaning legislators and professional reformers introduce, or have introduced for them, measures that on the surface seem harmless to any particular group and beneficent in their general intent, whereas close analysis will often show that if enacted into law such measures may not only seriously interfere with estab-

lished customs and business methods, but may even go as far as to have an effect directly opposite to that which is desired. "Eternal vigilance" must therefore be observed by the officers and legislative committees of pharmaceutical associations during legislative sessions and their activities can only be successful when they are backed by the moral and material support of the members of the profession, both individually and collectively.

An important factor that should never be lost sight of by pharmacists in discussing legislation affecting their calling or in requesting the enactment or the suppression of a proposed legislative measure, is the duty of the legislature toward the public which they represent. Laws are not intended to confer privileges upon a class. They are intended to protect the life, health, property, and liberty of the people. If in protecting the public health, a pharmacy law confers certain privileges upon the pharmacist, that is merely incidental and a correlative of the original intent of the law which is to protect the public against the dispensing of medicines by incompetents. A legislature would have no more right to pass a law limiting the ownership of a pharmacy or the dispensing of a prescription or sale of poisons to pharmacists than to pass a law limiting the selling of radio outfits to electrical engineers, were it not for the fact that pharmacy ownership, dispensing of prescriptions and sale of poisons are matters concerning the very life and health of every man, woman and child in the State.

The pharmacist will therefore do well to remember that pharmacy laws are not enacted to conserve his rights, but rather to protect the public against incompetents by limiting the practice of pharmacy to those having proper qualifications.

With the many "side lines" that are creeping into the merchandising end of pharmacy it is also advisable to keep in touch with the legal requirements governing the sale of such items. This can be done through membership in chambers of commerce and other organizations of business men.

Executive Functions

It has been said that every institution is the lengthened shadow of some individual. This is particularly true of a retail business. The proprietor's policy is reflected throughout the entire establishment. If his clerks are pleasant, reliable, and give good service, he is credited by the public with maintaining a progressive shop. If they are grouchy, careless, and indifferent to customers, the proprietor is condemned for their acts. Employing the right kind of help from the registered pharmacist down to the errand boy and porter is therefore a very important function of the head of a business organization.

Selection of Help—It is well to obtain all possible information bearing on the character, habits, and abilities of the prospective employee. Large firms use a form of questionnaire or application blank on which to record the information desired and it is highly advisable for even a small business to follow this procedure. One is very apt to forget to ask some questions of the applicant which are essential unless a note has been made of them before the interview. It is not neccessary to have a printed blank, but the necessary questions to which answers are required should be set down and either verbal replies should be obtained and recorded or the applicant should be asked to write out his answers. References ought to be looked up carefully since the information obtainable from previous employers may decide the question as to whether one or another applicant with similar qualifications is the better suited for the position in question, always making due allowance for the possible prejudices of a former employer.

The following form of application is used by R. S. Sherwin, manager of Petty's Pharmacy, a large retail firm located in Newark, N. J.

APPLICATION FOR EMPLOYMENT

Department.....
Name..... Salary.....
Address.....
Age.....Married or Single.....Experience.....
Registered Pharmacist.....College Graduate.....Nationality.....
Father's (or mother's) name.....
Address.....
Last place of employment.....
How long there.....
Employed in what departments and how long in each.....
Left or discharged.....
Reason for leaving.....
All other places of employment in the last five years.....

Do you use tobacco?.....Cigarettes?.....Beer?.....Liquors?.....
I have read the above and all answers are truthful
Date..... Signed.....
.....

These blanks furnish complete information of a routine nature which is helpful in making a decision but it is most unwise to engage anyone without a personal interview. Much that cannot and will not be said on an application blank or in a written communication comes to the surface in an interview guided by intelligent questioning. The human factor is the greatest of all in the employing and handling of help. "Failures" working for an average employer often become outstanding "successes" under employers who know human nature and who can bring the best out of an individual by sympathetic and judicious handling. The following comments by E. H. Cone of the E. H. Cone Inc. Drug Stores of Atlanta, Ga., on the employment of help, are pertinent and indicate the broad view which employers in this generation are taking of the help question:

The following form is used by E. H. Cone Inc. for applicants to the various departments of their stores in Atlanta, Ga.:

APPLICATION FORM

Fill out in your own handwriting and return in person or mail to above address

Date.....192.....
1–A Name.....
1–B Address.....
Street and Number City State Phone
2–A Name of person with whom you reside?.....B–What relation?.....
3 Born at.....B–Age.....
4 In what places have you lived?.....
5 Married or single?.....6–Religious affiliation?.....
7 Who is dependent upon you for support?.....
8 Give father's name.....B–His occupation.....
9 What position do you now hold?.....
B Name of company or employer?.....
C How long so engaged?.....D–Salary.....
10 Why do you wish to change?.....
11 What is it your ambition to be?.....
12 What are you doing in self-development to reach that aim?.....

APPLICATION FORM—*Continued*

13 Give record of previous employment—fill in accurately:
Company or employer: Address: Time (dates) of service Salary rec'd Reason for leaving:.....
.....
.....
.....
.....
14 Name schools or colleges you have attended?.....
.....
B What grade or class did you finish?.....
C Do you operate a typewriter?.....
D Are you registered?.....Date.....State.....
15 Name some of the books you have read in past six months?.....
.....
B What magazines do you read regularly?.....
16 To what social, athletic, religious or military organizations do you belong?.....
17 Have you a hobby?.....B–If so, what?.....
18 What exercises, recreation or amusements do you have?.....
.....
19 Are you:
Careful?.....Patient?.....Thoughtful?.....Nervous?.....
Optimistic?.....Orderly?.....Active?.....Calm?.....
20 What illness have you had in past three years?.....
B Is your eyesight or hearing defective?.....
21 What is your height?.....Weight?.....
22 How many cigars do you smoke daily?.....How many cigarettes?.....
23 Have you any income other than your salary?.....
24 What is the approximate amount of obligations you now owe?.....
25 Give name and address of 3 references not related to you and by whom you have not been employed:.....
.....
.....
26 Tell in a general way what plans you have for the future and why you think you are adapted to our line of work?
.....
.....
.....
.....

.....

"Can he smile? Smile naturally because he feels that way, I mean. That is one of the first things we want to know. To be a good salesman a man—or a woman—must be happy, friendly with the other people in the store, good humored. He must not be harassed by debts. He must be well. That is the type we try to engage.

"There are certain physical, visible qualities we prefer in engaging a clerk. For instance, he must not be above the medium height or weight. Why? Because this type is light upon his feet; he does not tire so easily from standing. And he moves about more freely in the restricted spaces behind the counter and between the cases. He does not have to squeeze past customers in the aisles.

"'Qualifications for Employment with E. H. Cone, Inc.', is a printed sheet containing twenty-six questions and blanks for the answers. After the name, address, and age, is the question 'With whom do you reside?'.

"We prefer clerks who live with their families; especially in the case of girls. They are better cared for, happier. We ask also whether anyone is

dependent upon them, for we want to know whether the salary will meet the demands upon it.

"We ask what position the applicant now holds, how long he has been there, what salary he earns. We want to know why he desires to change. If it is for some trivial reason, some disagreement, we advise him to go back, forget his troubles and stick. If he is willing to come to us for the same salary, we want to know what is the matter at the old place. If he wants a very material increase, we want to know why he thinks he can earn so much and why he did not have the chance with his present employer.

"We inquire whether he has any income other than his salary and the approximate amount of his obligations. A clerk burdened by debts, in the hands of loan sharks, harassed by demands his salary cannot meet, cannot do justice to himself or his employer. We have helped promising men out of such troubles, arranging for a gradual repayment and putting them on their feet. It made new men of them.

"We ask first of all about an applicant's health, whether he has been ill in the last three years and whether there is likelihood of its recurring. The health of a clerk is vital. If he is run-down, below normal, he cannot do his best work. We have had men who appeared to be slipping backward and we took them to a physician for examination. A bit of advice as to diet, a recommendation to take exercise at the Y. M. C. A., did wonders. We are glad to see that they have the opportunity to improve their health.

"A man's sight and hearing are important. If his hearing is defective he cannot answer the telephone properly and he is likely to annoy customers by failing to understand. If he does not see well, he is handicapped also.

"We ask how many cigars he smokes daily, or how many cigarettes. Smoking does not bar a man from our employment, but we like to know if there's an excess. We prefer a cigar-smoker to a cigarette-smoker. The latter is tempted to slip out frequently for a puff or two, and if he smokes too much his fingers are stained.

"We prefer married men because they take their work more seriously. We do not like employees who have made many changes, for they are not likely to stick. It is poor economy to keep hiring new men and we do not desire to engage men who wish a mere temporary place.

"Many of these matters are those in which employers would interest themselves, though perhaps not too systematically, but the Cone application blank goes further. Here are some of the questions that may be considered as odd:

"'What is it your ambition to be?'

"'What are you doing in self-development to reach that aim?'

"'Name schools or colleges you have attended.'

"'Do you operate a typewriter?'

"'Name some of the books you have read in the last six months?'

"'What magazines do you read regularly?'

"'To what social, athletic, religious, or military organizations do you belong?'

"'What exercises, recreations, amusements do you have? Are you careful? Patient? Thoughtful? Nervous? Calm? Optimistic? Orderly? Active?'

"'Tell in a general way what plans you have for the future, and why you think you are adapted for our line of business?'

"It is not merely the answers to these questions that count, but the way they are answered. We can get quite a good line on an applicant's character from the way he fills out that blank.

"Having graduated from a college is not a requisite. A clerk need not be a

typewriter operator, although it is convenient in prescription work. We would not bar a member of the militia. On the contrary we would be glad to have him, and would see that he could go to the encampment.

"But we do like to have a fairly intimate knowledge of the individual side of our people, their human characteristics. We like to know what they are interested in, what the natural turn of their minds may be, their temperaments. It will help us to place them in just the work they are most adapted to.

"And of course the interview with the applicant tells us a great deal more than he puts in words. If he is resourceful in applying for a place he will be resourceful in waiting on a customer. If he is slow in understanding; hesitant; if he does not look you in the eye, if he is not at ease, these are all points against him.

"The goal all modern employers are striving for is 100-point men in moral character, health, previous training, appearance; men above the normal. We may never reach that goal, but the nearer, the better."

Supplying References—References should be cheerfully given regarding former employees when asked for by prospective employers and the information sent should be fair, impartial, and straightforward. This is a business courtesy that is valuable to both the employer and employee and should be placed by employers on a basis of mutual helpfulness. Courtesy also demands that unsuccessful applicants who may have spent much time and effort in making application, be notified that the position has been filled.

It is well to establish a salary schedule that is graded on the basis of time of service and efficiency. If a profit-sharing scheme can be worked out, this will be found most satisfactory because it keeps up the interest of the employee. Many clerks who know they have reached the maximum salary which the store can afford to pay are apt to lose interest in their own productiveness and simply do the day's work without special effort to improve their value to the business.

Sometimes a druggist is influenced by the apparent economy of low wages. A registered man being paid $65 a week may very well be worth three times as much as the one who will work for $35 a week. Fair and even liberal wages tend to bring a reward out of proportion to their extra cost. In addition to an increased interest in the welfare of the store, the feeling of goodwill engendered has proved over and over again a strong deterrent to petty thievery of merchandise and cash.

If the proprietor pays living wages he can conscientiously insist upon the utmost care in the handling of his merchandise and cash. The LaWall Business Record System (described on pages 1202 to 1421) provides without extra work an excellent means of checking stock and cash leakages. Suppose the expenses and profit have been found to average 35 per cent of sales. On the 20th of each month, note the total sales for the month up to that time. Compare this total with the corresponding figure for purchases. If purchases exceed 65 per cent of sales, obviously something is wrong. The intelligent proprietor can learn very readily the cause once he knows there is a cause for investigation. The trouble may be overbuying, a falling off in sales, with no corresponding decrease in expenses, too low selling prices, or thievery by customers and employees.

It is unfortunate that dishonesty is not an uncommon trait among employees. For the protection of the business, as well as the clerks who are honest it is important to keep a close check on inventories and sales in the various departments so that leaks may be detected immediately and proper steps taken to eliminate dishonest employees. Profit-sharing schemes, bonuses, and

other methods of compensating clerks for resultful efforts may help to keep them out of temptation to take what does not belong to them.

Happily the long hours of service required in former days of both proprietor and clerks are giving way to a more rational adjustment. Whenever possible the help should be worked in shifts which will reduce the labor of any individual to a number of hours per day comparable with those of other business organizations. Drug store employees are entitled to their periods of recreation and will give a better account of themselves during business hours if they are given sufficient time for rest and relaxation.

Relation to Other Business Men in the Community

It is expected that a pharmacist will govern his relations with other members of his profession according to the Code of Ethics adopted by the American Pharmaceutical Association and most state and local pharmaceutical organizations (see page 9). The basis of this Code of Ethics is the "golden rule" and it can very readily be extended to include the relations of the pharmacist as a business man with other business men in his community.

The pharmacist may learn a great deal from other merchants and contact with them through personal association or through the medium of civic clubs, chambers of commerce, etc., will often prove decidedly beneficial. Every merchant owes a certain responsibility to the community upon which he draws for his business success. The pharmacist is considered more than a merchant so that he should stand out among his fellow business men as a personification of all that is good in their methods of doing business plus the unselfish service which he is supposed to give as a professional man.

In his relations with other business men, the pharmacist should be very tactful. He is often open to criticism because he handles many articles of merchandise which other stores consider their legitimate field. He should not be too critical of his fellow merchants and if there are occasions when the grocery man or hardware man attempts to sell drug products or poisons which are regulated by the pharmacy laws and which he therefore has no right to sell, it is better to instruct the other merchant in the legal phases of the matter and endeavor to dissuade him from breaking the law than to incur his enmity by reporting him at once to the authorities. It is plain, of course, that it is the pharmacist's duty to help enforce the law and if the general merchant does not yield to common sense entreaties, there is nothing left but to resort to legal measures.

The pharmacist should join other merchants in all endeavors to uplift the community in which they are doing business. Movements to keep business in the community, to carry on civic enterprises on a high plane, to educate the public to the use of better goods, thereby effecting certain economies, are all worthy objects and should be entered into whole-heartedly.

Relation to the Public

As the head of a business organization which combines professional service and merchandising, the pharmacist has a twofold relation to the public. As the professional man he is their counsellor in times of ill health and other misfortunes. It is common for people in the neighborhood to turn to him first for advice of all kinds because they expect him to be a man of better education and greater general knowledge than any other business man in the community. In order that he may live up to the qualifications which the average person expects of him, he must maintain a certain poise and

dignity which are essential qualities in the professional personality. It is important that he should have good health. So much depends on the head of a business that he owes it to himself, to his family, and to the community which he serves, to maintain himself in the highest state of efficiency at all times in so far as this is humanly possible. The confining atmosphere of a pharmacy is not conducive to good health and the proprietor should therefore make it a point to get out into the open at regular intervals, to seek change and recreation from time to time, so as to maintain his good nature and general efficiency.

In order to live up to the public conception of the head of a business organization, the pharmacist should be fairly prosperous. It is not necessary to possess or acquire great wealth but more than the ordinary income is required to take part in the various community enterprises to the same extent as the average successful business man. To this end, money should not be squandered on questionable stock promotion schemes and other get-rich-quick propositions. A reserve for expansion of the business and to provide the wherewithal to live up to his station in the community should be acquired as early as possible.

Most persons are apt to think a great deal more of the man who is honored by his own craft and who achieves distinction in his own line of work than of the individual who is never heard of or written about in contacts with his professional brethren. When the pharmacist is active in the work of his local, state, or national association, it is the part of good business to let the local paper print news items regarding his activities. Such information appearing in the papers enhances his prestige in the eyes of customers. It should be remembered, however, that in order to achieve distinction in any profession or business it is necessary for the individual to put far more of himself into that profession or business than he can ever hope to get out of it. If association work is undertaken merely for the popularity and distinction that may come to the individual, it will be unsatisfactory both to the association and to him. His sole idea in entering such work should be to give service to his craft. The rewards are incidental and the publicity feature is cited in these pages chiefly because so many pharmacists in the past have rendered service deserving of recognition and have never permitted the fact to become known, while others who have done much less have been heralded as public benefactors simply because they had a little chat with a newspaper reporter or editor now and then.

The great advantage enjoyed by the independent storekeeper over his chain store neighbor is that people like to deal with individuals rather than with corporations. The individual storekeeper should take full advantage of this situation by cultivating acquaintance with his customers, learning their peculiarities and endeavoring to take a personal interest in them. There is a double advantage in this, for not only does the customer have increasing confidence in the proprietor or clerk with whom he stands on a friendly footing, but it gives the storekeeper a clearer insight into the manner of people who make up his trade. The local merchant is really a buyer for his community. He represents them in the larger markets. To do this intelligently he must know the limitations of the community in which he does business but his endeavor should be at all times to improve those limitations. If he builds upon his experience wisely, he can decide very quickly whether a proposed new product will "take" or whether it will fall by the wayside. Large manufacturers lament the fact that they cannot get information regarding distribution of their products through retail storekeepers. Very often it becomes

necessary for them to send representatives into retail stores to get the viewpoint of the consumer. A wide-awake retailer should be able to give this information quite accurately, for no one has a better opportunity than he to observe the wants and desires of his community.

It is wise to establish a definite policy for a retail store which is elastic enough to provide for the constant changes that are taking place in our community life, especially as that relates to the pharmacy. The establishment of a policy involves a decision as to the kind of goods to handle. In some cases it is necessary to handle cheap, medium priced, and high priced articles because there are three distinct groups of customers. In other communities only the very cheapest kind of merchandise will have any sale and in still others nothing but the highest quality products can be sold. Investigation before entering upon the business will reveal the proper adjustment of the policy in this respect to some extent but only actual experience can verify it.

Whether to do a cash or credit business is another feature of the store policy which must be decided. In most cases a cash business is preferred but there are communities where it is impossible to do business excepting upon a credit basis. It would be suicidal for a pharmacist to attempt a cash business in such a location. A credit business naturally involves additional expense and prices will have to be adjusted to take care of this.

How far to go in the merchandising of non-pharmaceutical products is becoming a more difficult thing to decide each year. People think of the drug store as a service station and largely because of the fact that it is open during hours when other retail establishments are closed, it is expected that the drug store shall have on hand many articles of merchandise ordinarily entirely foreign to drug store commodities. The temptation to yield to the demand for constant increases in the side lines handled is very great and it becomes more difficult all the time to decide where to draw the line. It is plain that the line must be drawn somewhere unless the drug store is to become a department store entirely, with only a small drug and prescription department.

A safe rule to follow in the average neighborhood drug store is to remember that the pharmacy enjoys its reputation and popularity largely because of its professional aspect. If this is subordinated entirely and the pharmacist goes into active competition with practically every merchant in his community, he will soon find a combination of those merchants arrayed against him and he will not only lose much of his merchandising business but also his professional prestige. The "live and let live" principle should prevail.

Relation to Physicians

The Code of Ethics of the American Pharmaceutical Association is very explicit in its rules governing the conduct of the pharmacist with physicians. Tact is the great requirement here. The pharmacist stands between the physician and the public and in this position he may be subject to abuse from both but he can cultivate the friendship of both to a degree which will help him over many awkward situations.

If it should happen that a physician carelessly writes for an overdose of a potent remedy and the pharmacist detects the error, the incident should end with the detection and correction of the error. Under no circumstances should the pharmacist use the incident either to injure the physician or to exact tribute from him in one form or another. The pharmacist never knows

when he or someone in his employ may make an error in compounding and when he will want the help of the physician in correcting such an error with the least possible harm to his reputation. There should be no secret arrangement between the physician and pharmacist as to formulas for prescriptions, or rebates, or commissions to the physician. Such arrangements always lead to misunderstandings and suspicion and serve no good purpose in the end. The pharmacist should be rewarded for his professional work and the physician who writes a prescription is not conferring any favor upon the pharmacist. He is simply doing his duty by the patient and depends on the pharmacist to give the necessary compounding and dispensing service.

It is not the pharmacist's province to diagnose disease. He is not trained along this line and should never attempt to take the life of a patient into his hands by prescribing over the counter for what may seem to be a minor ailment. Many an unfortunate victim has been lulled into a false sense of security by following unskilled advice on what to take for a certain pain.

In the matter of giving medical advice and administering first aid, the pharmacist is called upon again and again to use the greatest tact. Ignorant people cannot understand why a pharmacist with all the medicine that is around him cannot mix up some sort of a concoction which will restore them to health and they frequently attribute the pharmacist's advice to see a doctor to commercial motives. Even at the risk of such suspicions the pharmacist should always maintain this ethical position. If he is asked to sell a certain product he may do so, but recommending a product for a given set of symptoms is wrong and should not be tolerated in a high class pharmacy.

When there is an injury to someone from an accident nearby, it is natural to run to the pharmacist for first aid. Here again, it is important for the pharmacist to know his limitations. He should immediately send for an ambulance or for a physician and only employ such emergency measures as are plainly indicated as necessary by the conditions.

CHAPTER LXXXI

THE STORE OR PLACE OF BUSINESS

To DEVELOP a professional or commercial retail drug business there must be an opportunity for service; that is, there must be a public demand for it. The *location* of a store therefore becomes a vital factor. There must be prospective customers somewhere within a reasonable distance, and real professional service is only possible when physicians and dentists are also nearby. Most of the purely professional pharmacies in the United States are located in or near "medical buildings" or in a medical center. In an outlying, thinly populated territory, where but one physician is found on a twenty mile drive, but little prescription filling or clinical analysis could be expected. Here, however, there might be very important professional opportunities for the pharmacist in helping to maintain community sanitation and health.

The distance customers must travel to reach the store has a number of important effects upon the character of the store's business. If people must come ten to twenty miles, their visits will not be as frequent but their purchases on any one visit will be larger. (Incidentally, the extent and condition of roads and other transportation facilities has a determining effect upon the extent of the territory from which the store can draw.) Such a store has the possibility of developing a mail order business. It may also find an automobile delivery profitable.

In stores where automobile delivering is required, it should be watched very closely, as the cost of light truck maintenance and operation is often much more than the sales justify and the service is not always appreciated at its full value by the customer.

These services naturally add to the cost of doing business; an attempt to do a cut-rate business under such conditions would be suicidal. In the thinly settled sections of a city, where many customers must come several blocks to reach the store, the proprietor may expect to do a large telephone and delivery business. The opening of charge accounts may also become necessary (see page 1391). In such a store, window and store displays do not have the drawing power that they have in a transient location and the proprietor therefore must resort to circular letters, handbills, billboards, and perhaps advertising in the street cars to attract trade.

The selection of a location therefore calls for a careful consideration of the conditions.

In selecting the place of business, it is well to bear in mind that the 22,000,000 automobiles in this country provide gasoline transit for practically every family. With the rapid increase in good roads, a decided change has been made in the entire structure of retail business. People will travel from eighteen to twenty miles to a shopping center, or, in other words, will give an hour of their time to reach a city or town that is an accepted shopping center. Progressive towns with active retail associations, bright show windows and good theaters are growing rapidly in their volume of retail business.

In selecting a location, therefore, the druggist should pay more attention to the activities of the neighboring stores rather than for the actual population of the town. In some sections, such as in West Virginia, a town of 500 often has a drawing power of 5000 to 10,000 people and a town of 5000 will often

support six or seven prosperous drug stores. In short, the business man should look behind the superficial figures and analyze the real facts.

When our communities were small and the pharmacist's business was largely in drugs and medicines, the location of his store was not a great problem. He usually fitted up his laboratory and storeroom near the business center of the community and whether it was on a corner or in the middle of a block was of little consequence because the people had to come to him for their medical supplies. Things are vastly different now. The matter of location of a store has a tremendous influence on its possibilities of success. This is true because the rapid development of our cities and the multiplication of our activities as a people require conservation of time and effort. It is therefore only natural for people to go to the most accessible establishments for their supplies of all kinds, other things being equal.

The druggist need not feel, however, that limitations upon his natural trading area forever circumscribe his activities. Anyone familiar with drug stores knows that some druggists attract trade from wide areas in spite of natural limitations. There are drug stores in American cities which fill prescriptions and sell other merchandise to persons all over the world. In general, there are three influences which help to extend a store's normal trading area. They are:

1. Character of the service rendered.
2. Extent of the stock carried.
3. Prices.

Location of the Store—It is impossible to lay down definite rules for the location of a pharmacy which will cover all cases. The so-called transient store must be situated where it will attract the greatest number of people in a given time. The neighborhood store, while commonly located at a corner, has often been successful even though it was located in the middle of a block. In smaller towns and rural communities it is customary for the pharmacy to be located in what is known as the business center or main street. Very often three or four stores are found within one block of each other in such towns, each one serving its own clientele and having established its trade among the farmers and others who come to town to do their shopping at stated intervals.

Transient Location—Transient customers are not such a factor as they were once thought to be. Chain stores have almost discarded the idea that their customers are transient even in the busiest sections of the city and are endeavoring more than ever to build permanent customers. For instance, in one busy chain store on Fifth Avenue near 42nd street, New York, the manager says that less than 10 per cent of his volume is from transient customers. To prove this he points out that at the soda fountain the same faces can be seen there at the same hour every day. The transient customer is not, as a rule, a profitable customer but the fact must not be lost sight of that nearly every transient customer is a potential permanent customer and he should be treated with the end in view of making him a regular supporter of the store.

In opening a store for transient business, which will naturally depend for its trade on the people that pass, it is important to be able to decide which of several locations may be best. Given any four corners in a large city there will always be an advantage at one intersection over another. This advantage may be brought about by the fact that street cars or buses may stop at one corner and not at the other or there may be a large office building, theater, auditorium or department store closer to one location than to another, and this of course means that a larger number of people will pass one particular point in twenty-four hours. There is only one way to decide intelligently

on the advantages of a location of this kind and that is on the basis of facts. An investigation of the immediate neighborhood of the location is necessary.

Consideration should be given to the character of the surroundings of the proposed store. Women form the largest proportion of the patronage of a pharmacy. Surroundings which are distasteful to them should be avoided. For instance, billiard rooms, garages, and saloons are poor neighbors for a pharmacy. The physical appearance of the store itself also affects its value. Good window display space can be used effectively to increase sales and consequently enhances the value of the property. An awkward entrance and interior arrangement decreases the value of a location. Large chain stores organizations desiring to determine the advantage of one location over another will frequently station observers at various points and will actually count the number of passersby during certain hours of the day so as to determine where the most people pass. They will further analyze the situation from the standpoint of whether these people are on their way to and from business or whether they are more or less of a leisure group with time to glance at window displays and with sufficient interest to step into a store and buy. It may easily happen that more people go by one location than another but that the percentage of possible buyers in the location where fewer people pass will be greater than where the larger number pass. As a general rule, however, it can be demonstrated from actual observation that the gross sales of a transient store will be greatest where most people travel because ways and means are devised to interest a certain percentage of those who pass, in the merchandise for sale.

The question of rent naturally enters into these calculations. It may be found more economical to take a corner where there are fewer passersby, at a reasonable rent, than to occupy another corner where more people will pass but where the rent is exorbitant or the lease unsatisfactory. Transient stores like any other type can attract people by their advertising, their service, and their merchandise values, but in this highly competitive commercial era these factors are apt to be well taken care of by all store owners and it must be borne in mind that people will not cross a street, especially in a busy section, in order to trade with a certain merchant if they can get what they want under equally satisfactory conditions on the side of the street on which they happen to be. If one contemplates the opening of a transient store in a city or town not well known to the prospective owner, it is advisable to consult reliable real estate dealers, officers of the local chamber of commerce and merchants in other lines, for the purpose of gaining as much information as possible about the present and future development of the business section of the town. Very often the business districts of the city have developed in an entirely different direction from that planned by the founders. In the older cities the trend of business is well established, but in growing towns it is sometimes difficult to determine the direction of future growth if there are possibilities in more than one direction. The newcomer should not depend entirely on his own judgment or that of friends. It serves his interests best to obtain information from as wide a group of people as possible before coming to a definite decision.

It is important to study beforehand not only the characteristics of the location itself, but also those of the area from which the store expects to draw its trade. If the store is located in a city or neighborhood which is growing and which has every indication of continuing to grow, the proprietor may expect a normal increase in his business, solely as a result of this growth. On the other hand, if the population of the community is stationary or declining, constant

and increasing efforts will be necessary merely to maintain the volume of business that he has.

As a further consideration, any changing tendencies in the population should be noted. A fine residential section may be rapidly becoming a center for rooming houses. Native American workingmen may be in the process of being succeeded by recent immigrants. These changes do not mean necessarily a loss of business but they do mean a change in the character of the business. The proprietor should consider himself in relation to these changes. A pharmacist may be very successful in serving a high class residential clientele, but a flat failure in dealing with recent immigrants. Likewise stock which would be salable in a high class residential section would be entirely unsuited to the demands of foreigners, not yet accustomed to American habits of life.

Buying a Transient Store—When it comes to buying a transient store which is already established it is important to get all of the facts about the business of that store not only for the past year but for the past ten years, if possible. Such information will immediately show whether or not there has been a steady decline or a healthy increase commensurate with the general growth of the section, and it may also reveal the real reason for the owner's desire to sell. If a transient store has for any reason acquired a bad reputation, it should be remembered that a considerable expenditure will be involved in correcting that reputation. If at all possible, the building should be purchased with the store. If this is not possible, the lease should be very carefully investigated. If it has only a year or two to run, there is great danger that when the lease expires the rent will be greatly increased, perhaps beyond the amount justified by the business that may be done at that location. It is not uncommon in the present day of growing real estate values, when old leases expire for rents to multiply fivefold and more, for desirable locations. In this matter, as in any other involving legal phases, it is most advisable to consult a competent attorney and to have the benefit of the advice of a reliable real estate man.

Neighborhood Location—The selection of a location for a pharmacy in a neighborhood section presents problems of a slightly different type than those mentioned in connection with the transient store, although most of the factors applicable to the transient store apply with more or less force to the neighborhood store. Assuming that a new store is to be opened, it is important to inquire into the character of the neighborhood, the possible number of people that might reasonably be expected to trade at the store, taking into consideration the proximity of other pharmacies and the tendency of the people to buy in the down town sections. In addition to studying the potential buying power of the people, it is also advisable to consider what percentage leave for summer or winter homes during a part of the year, whether or not they depend for their income upon one industry which may be subject to shutdowns or strikes and any other local factors that may influence business. The greatest mistake that the prospective owner can make is to go into the proposition blindly. The facts are obtainable and should be sought.

Builders who are developing new sections of our cities usually make preparations for the location of stores of various kinds. If one contemplates the opening of a pharmacy in a new section and storeroom is provided, it is well to consult with the builder and give him some idea of the peculiar requirements of a pharmacy in the way of space and layout.

The question of ownership and the possibility of obtaining a satisfactory lease holds good in this case just as in the case of the transient store. When an established business is to be purchased, it is well to ascertain the following facts: The total annual volume of business, with information as to its increase or

decrease in the past five years or more; the character of the business done in the store, that is, whether it is largely in package medicines, in side lines, in prescriptions, in loose drugs and products of the pharmacist's own manufacture, or in soda and confectionery; the character of the community, whether it is rich or poor and whether it is possible to educate the neighborhood to purchase its pharmaceutical needs near home rather than in the transient districts where the people work or shop; the reputation of the present owner in the neighborhood, in other words, the value of his goodwill; the reason for selling the store; a careful investigation of the prices at which goods are sold to determine whether or not a reasonable profit is possible. All of this information coupled with a careful inventory and satisfactory arrangements regarding lease or purchase of the building should be at hand before a decision is made to buy.

It is also wise in all cases to obtain an option to buy the building, as a part of the lease, so as to avoid the possibility of having the building purchased over one's head by a competitor.

The location of a new store or the purchase of an established store in a small town requires consideration of all of the factors, in a greater or lesser degree, which have been outlined under the transient and the neighborhood stores.

Of course, no location can be considered perfect and it is important for the pharmacist to know both the advantages and the limitations of the particular site selected. Knowing this, the policy of the store and its management can be so adjusted as to overcome disadvantages of the neighborhood and to profit fully by its advantages.

Location is of course important but it is not always the greatest factor in the success of a store. Some druggists are unsuccessful in merchandising even in the best locations, whereas others will be successful in localities which ordinarily are considered extremely poor.

Name of the Store—The name of a store in a transient location is a very important asset. If the business has been conducted by a reputable individual whose name is attached to it and has become fixed in the minds of the people of the community, it would be folly to change that name, although it is entirely proper to advertise the name of the new owner in connection with it. If on the other hand, the former owner has not enjoyed the confidence of the public, it would be equally unwise to continue the establishment under his name. It is difficult for the public to disassociate names and personalities. The thought of the former owner and his lack of service or other faults will come up in spite of the knowledge that a new man is in charge, if the former owner's name is continued.

Very often a substantial sum is paid as part of the goodwill that goes with the sale of a store for the name under which the establishment is known. It is to the interest of the new owner or the prospective buyer to establish by inquiry and observation the value of the name to the store. The name of the individual associated with a store lends a personal touch and is to be preferred whenever possible even in a transient section. General designations, such as "Red Cross Pharmacy", "Purity Pharmacy", "Service Pharmacy", etc., are usually employed when the store is owned by a group, or when the proprietor has some reason for not wishing to use his own name. In such cases, it is difficult for the public to recognize the real owner and the store is apt to lose the personal touch which is so advantageous to any retail business.

It is true that some store owners today are thinking only of the establishment of a paying business, for the purpose of re-sale. In that case, impersonal names such as "Palace Pharmacy", "College Pharmacy", etc., seem to be

preferable, as they can be retained by the new proprietors without letting the public know there has been a change in ownership.

One of the chief assets of a neighborhood store is the fact that it is possible for the owner to cultivate acquaintance and friendship with his customers. It follows that the owner's name on the store window or over the door will carry more confidence and commercial value than an impersonal designation. In general, it would seem to be the part of business wisdom for every pharmacist who is in business to make his name the name of the business establishment.

One danger of handing down the name of an established pharmacy is the possibility that its reputation may not be sustained. This depends, however, very largely upon the manner in which the organization is continued. Many firms of established reputation have existed years after the founder had sold out and died and the original policies and reputation have been fully sustained. This is largely a matter of control.

What Should be Paid for an Established Store—Many elements enter into the final answer to the question "What should be paid for a store"? First, the location; second, the actual physical value of the fixtures and stock; third, the business being done and the net profit earned. Location and goodwill have already been discussed. Whatever is paid for goodwill should be charged off to a large extent within the first year, for after a short time the continuance of the patronage of the community will depend on the personality of the new owner or manager. A strategic location has a value which must be paid for and which can always be redeemed. The value of the physical equipment will depend upon age and adaptability to the present demands of the community. Today, many consider ten years as the life of fixtures and soda fountain and consequently write off ten per cent depreciation each year. If the store will have to be refurnished to bring it up to date, the old fixtures are worth nothing to the new owner. He probably would not be able to give them away if he wanted to dispose of them. It is a wise plan to ask the judgment of a good store fixture man before agreeing upon the value of the fixtures in an established store.

The value of the stock should be determined on the basis of a recent inventory. It is folly to buy on the prejudiced guess of the one who would sell. A real inventory by a disinterested and qualified third party should be insisted upon even if made at the buyer's expense. There are always men in wholesale drug houses trained to do this and it will give a real basis for value in discussing the sale price, and if the sale is consummated, it gives the new proprietor correct figures for starting his accounts. An inventory has other values but these will be discussed later (see page 1417).

The value of stock in the store should be determined not alone by its inventory. Stock which is salable in one store may be useless to another. For instance, a store removed from the central section of a city and serving a workingmen's neighborhood can sell many novelties which could not be handled by another store whose customers are wealthier and accustomed to shopping downtown. The inventory should be studied to determine the quantity of unsuitable or slow-selling items and allowance made for them in determining the value of the stock to the prospective purchaser.

Store Arrangement—The change in the nature of the drug business, which has added considerable merchandising to the original function of the pharmacy, has brought with it necessary variations in the planning and arrangement of modern drug stores. When the pharmacy was almost exclusively a place where medicines were compounded and sold, it was only necessary to provide enough

room and proper facilities for the storage of the various drugs and preparations, a comfortable place for patrons to wait for their prescriptions, and perhaps a counter or two with an occasional display case. As the various side lines were added, it became necessary not only to provide storage space but also space for display. "Goods well displayed are half sold" is a phrase that is commonly used today and there is no question about the fact that much merchandise is sold because it is attractively displayed and can be seen and handled by the prospective purchaser. One of the great problems in organizing a new store is to know how to plan for adequate display for the various items that constitute the stock of the modern retail pharmacy. The matter of quick service is also of importance, and a store, particularly one of the type that is handled largely by one man, must be so arranged as to have things convenient for quick service. It is now customary to relegate the old time show bottles to the back room and to use all shelf and counter space for the display of attractive packages. Of course, the requirements of the one-man store are different from the larger stores where numerous clerks are employed and where these clerks frequently remain in one department and do not sell goods in other departments. There should be ample aisle room between wall and floor cases. Twenty-four inches of space is advisable and it is not safe to allow less than 20 inches in any case. Space at the front of the store is generally considered more valuable than space at the rear so that it is customary to lay out a store with the departments that yield a rapid turnover and good profit in the portions most accessible to the public. Very often the layout is so planned as to require customers to pass counters or cases where special merchandise is on display in order to reach the place where items frequently called for may be obtained (see also page 1310).

The fundamental principle involved in a store layout is that departments and goods be so grouped that maximum sales and profits result. This means that full advantage must be taken of every available space in the store which can be used to promote sales. Non-productive departments should be located elsewhere. Departments should be grouped, as far as possible, to distribute customers through the store.

On this and following pages are shown typical layouts for stores of varying dimensions. The dimensions of the store and its location will greatly influence the planning. It will be seen from some of the illustrations that it is possible to economize considerably on space if necessary and to secure a great deal of shelf space, counter space and places for keeping necessary things, such as wrapping paper, string, the cash register, etc., if proper plans are made. Very often only a limited space is available in a high priced locality and it becomes the problem of the druggist to get as much stock and the necessary things to work with into that space, as would ordinarily occupy twice the room in a more commodious store.

In planning the store it is wise to get the advice of experts. The designers and manufacturers of drug store fixtures have naturally had a great deal of experience along this line and this experience is available to the retailer for the asking. It is possible to obtain fixtures at various prices, depending upon the quality of the material, the workmanship, and the reputation of the manufacturer.

Creating Store Atmosphere—Every store reflects a certain atmosphere which becomes characteristic and is associated with it in the minds of customers. It goes without saying that the conditions should be pleasing. To make them so requires careful planning. What may be a proper atmosphere for a confectionery store, a stationery store, or a grocery store, would not do for a high class

pharmacy. Among the features which distinguish the pharmacy from the average retail store are the prescription and drug department which should be so located and so outfitted as to quietly dominate the store. In other words, there should be something which will immediately indicate to the customer that he is in a pharmacy and not in an ordinary merchandising establishment. There is, on the one hand the constant demand for making the store a greater asset in the merchandising field and on the other the necessity for maintaining a professional background. Some of the illustrations in these pages indicate how this atmosphere has been provided and maintained.

For those who are interested in conducting strictly professional pharmacies with a minimum of merchandising the illustration of the front of the store of Hynson, Westcott and Dunning, in Baltimore, will be of great value. It has been suggested that the decorative scheme of the store interior might follow along the line of some medicinal plant design (see J. A. Ph. A., 1917, p. 376). The old show globes which were characteristic of the apothecary's windows many years ago have their modern counterpart in some of our pharmacies, and, with their colored liquids sparkling in the ray of an electric light, they have the same attraction and create much of the atmosphere of the "show bottles" of old.

The entrance to the store should be inviting. Considerable time and effort has been spent by manufacturers of fixtures and other equipment in designing store fronts that are both attractive and efficient. One should aim to make the store easy of entrance. For this reason complicated doors and narrow entrance are to be avoided. There should be a pleasing display at the entrance if possible, so as to attract attention and hold the interest of the person about to enter.

Too much ornamentation should be avoided. The plain, rich looking type of fixture is more attractive to most people than much fancy work.

Store Fronts—In general, store entrances may be divided into two kinds. The ordinary straight store front with the window parallel to and in line with the edge of the sidewalk, and with windows running back on converging lines to the door.

Arcade store fronts have become very popular in recent years. They have one or more show cases located in the vestibule or store entrance, with passageways on the side, and at the rear of the show case. The arcade type of store front is generally impracticable for stores with a span of less than thirty feet. Such fronts should not be less than 10 feet in depth. Arcade fronts increase show window display space. They give shoppers an opportunity to examine displays without being jostled by the crowds on a busy street. They give a store a very attractive appearance from the street. In stores facing the south and west, arcade fronts are of value because they give less exposure to direct sunlight than the shallow straight type of store front. There is therefore little danger of fading in the displays. They are desirable for shelter in bad weather thus affording the passerby an opportunity of studying wares in a comfortable frame of mind conducive to sales. They permit of unit displays. On narrow frontages they permit maximum show window footage.

On the other hand, arcade windows are expensive. They hide the doorway and congest the store entrance. They take space from the actual selling space in the store. They darken the store to some extent. They require a larger amount of samples for display, increasing the possibility of losses from light, dirt, and handling. They are more difficult to keep clean and will require more of the window dresser's time.

Windows in the store should be shallow, about two or three feet deep from the street. Aisles in arcade store fronts should not be less than 5 feet wide.

Bulkheads should be about 18 inches high. The plates of glass in the front should generally be 7 feet 6 inches in height. Prismatic glass should be used for transoms in all cases where the maximum of daylight inside the store is desired. All angles should be made 90 degrees to eliminate reflections in the windows if this is possible.

The light sources in the vestibule ceiling should be few in number so as not to detract from the show windows. One good light is sufficient.

The General Layout—In the planning of a retail drug store, when newly established or if being refurnished, various objectives should be kept in mind. One objective is the stimulation of sales. Another is to arrange things so as to enable the minimum number of sales people to handle the business with

FIG. 440

Professional pharmacy of Hynson, Westcott and Dunning

the least fatigue. Mechanical efficiency is of great importance. By carefully studying mechanical efficiency in its relation to the human element, the cost of help has been materially reduced in the last ten years in one of the largest pharmaceutical organizations in the country. Figs. 442 to 444 illustrate the layout of drug stores as planned by organizations having large experience. It will be noticed that there are three primary divisions, and this is common to most retail drug stores. It should be understood at the outset that the character of the business planned will largely determine both the number of departments to be established and also the space allotted to each. If the pharmacy is to be strictly professional, then the number and the character of the departments will be materially altered. In other words where the entire store is devoted to the handling of drugs, prescriptions, sick-room requisites, and hospital and surgical supplies, a particular layout would be planned. An excellent illustration is seen in Fig. 440, representing one of the largest profes-

sional drug stores in the United States, namely, that of Hynson, Westcott and Dunning, of Baltimore.

While all large centers are now developing strictly professional pharmacies, their number is limited and, therefore, greater consideration will be given to the type of drug store so largely established at the present time in the United States. In these stores there seems to be a generally accepted classification into at least seven departments as follows:

(1) *Drug and Prescription Department*—This section includes in addition to prescriptions and poisons, household remedies, or other medicines which are not classified as package goods, and which must be sold through the intelligent control of a registered pharmacist.

(2) *Package Medicines*—In this department are included medicines of a proprietary character, also insecticides and veterinary remedies.

(3) *Hospital Supplies*—The items in this department consist of hot-water bottles, syringes, surgical dressings, bedpans, etc.

(4) *Fancy Goods*—This department primarily carries the perfumes, soaps, chamois, and brush goods of the old-time drug store, but today there may be added innumerable fancy novelties and other merchandise. Its scope seems to be almost unlimited in modern stores.

(5) *Candies*—The candy department may offer both bulk and package candies.

(6) *Cigars*—Proper handling of cigars, cigarettes, and tobacco, either loose or in boxes, involves facilities for their storage, under proper conditions of humidity.

(7) *Soda Fountain*—The scope of this department is a matter of personal opinion and opportunity.

In stores in transient locations the soda fountain frequently has become one of the most important departments in the store. A cash business and quick turnover make the department especially profitable. In addition, it acts as a magnet to attract people to the store, resulting in their making purchases in other departments. The emphasis given to the soda fountain in some stores has been frequently criticised. Objections are made to the sale of sandwiches and the performance of other restaurant services. These are undesirable, however, only if, as a result, the store tends to lose its distinctive character as a pharmacy.

As an illustration of efficiency in planning, the general organization of a Liggett store (see Fig. 479) may be studied with profit. It will be found that as the store is entered the soda fountain occupies one side near the front. On the opposite side is placed the cigar case with such other merchandise as men may want. Next to the cigar case is the candy department. These two departments being side by side, may be served by either one or two clerks. If two are provided, they may relieve each other during the meal hours. Next to these departments will be found, on one side, the hospital supplies and package medicines. Here again, if two clerks are provided, one may relieve the other during meal time.

Opposite these counters are the sundries, one or more clerks taking care of the sales.

The drug and prescription department is located in the rear of the store and is in charge of registered pharmacists.

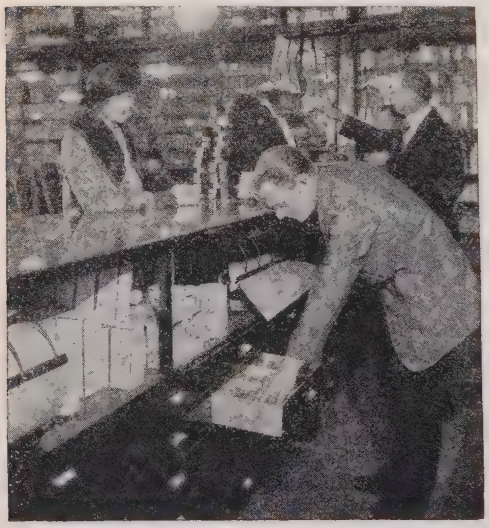
In such a layout the clerks remain within a small area and thus conserve both energy and time. It also provides a maximum of coöperative service.

The so-called one-man store can be arranged somewhat along the same lines but everything must be compact, the space available must be utilized to the

utmost and, above all, things should be so arranged as to save useless steps and thus conserve the energy of the one in charge.

The fixtures in all stores should be so constructed that they give the maximum of display, since this is an important factor in sales. The cases should also be accessible to the clerks. Several more or less standard plans are in vogue. In one arrangement the counters are placed in front of the wall cases and this is approved by many who have carefully studied various layouts. Other experts advise the use wherever possible, of wall cases only, so constructed that the bases and tops offer a large display area. It is argued that this type permits the clerks to stand in front of the case and readily reach the specific item in which the customer is interested, there being more or less difficulty when the clerk stands behind the counter and tries to find an item in the case which has been pointed out by the customer.

FIG. 441



An efficient sales and wrapping counter

The general *drug sales and wrapping counter*, illustrated in Fig. 441, shows a careful study of the principles of efficiency. The rolls of wrapping paper are accessible immediately below the counter but do not occupy valuable display space. The entire back of the case is arranged with drawers, suitably partitioned, and in which may be placed many of the small items that are frequently called for. The object again is to give quick service, save the clerks' time, and reduce the amount of physical labor required. The front of this case carries an appropriate display, special bins being provided for sponges or similar merchandise. This counter is made by the Wm. B. McLean Manufacturing Company.

The type of show case used will depend somewhat on the other fixtures. If the room is narrow, wall display cases will probably be more efficient than display cases in the center of the room or counter display cases. An effort should be made to avoid the appearance of crowding even though it is necessary to use every inch of space. It is now possible to obtain units which will give satisfactory display and at the same time avoid the appearance of crowding. Enough has been said on this subject to indicate that the planning of a layout for a store and the decision of the kind of fixtures to use require the most careful study and that proper layouts and fixtures will contribute very largely to the financial success of a business.

Display Fixtures—The furniture in a store, including wall and counter cases, stock shelves, prescription and laboratory equipment, etc., is generally referred to as fixtures. We distinguish, in this discussion, between permanent fixtures, such as wall and counter cases and movable fixtures, such as special types of show cases, tables, soda fountain, etc.

In selecting the style and quality of furniture for a store, attention should be given to the natural light, location and size of the shop. A dark location

may be brightened by the selection of light fixtures and a very bright store may be toned down by the selection of dark fixtures. Beech, birch, elm, gum, mahogany, oak, Circassian walnut, and willow are the woods generally used, with oak and mahogany finish predominating.

The lightness or darkness of the room is not however the vital factor. First, because the natural light that flows into the room is often a disadvantage rather than an advantage since it casts a shadow on the front of the goods. Light bills are the cheapest advertising the store has and the vital factor after all is to set the merchandise off to advantage. Great retailers like Wanamaker, Liggett, and Marshall Field, have studied this. There is no color that sets off the items of display better than rich tone mahogany.

The druggist is interested in selling, and therefore in showing his merchandise. His fixtures are simply a necessary piece of machinery, but in providing conveniences, the fixtures should not conflict or compete in any way with the display. The fixtures should merely be a frame that sets off or accentuates the merchandise. As a matter of fact, the actual amount of square feet area of fixtures showing, should be so small that they could not detract either from the display or from the lighting. Inasmuch as most drug store merchandise is light, the equipment to show contrast or accentuate display should be dark.

Fixtures vary in price according to the quality of material and workmanship. It pays to buy something that will last and will not lose its attractiveness. First cost is not always the main consideration. Something substantial and conservative is to be preferred to gaudy furniture that covers up poor quality of material and workmanship.

The manufacturers of fixtures will gladly submit sketches of furniture with the general layout so that the buyer may visualize just what he is purchasing. Furthermore he may incorporate some ideas of his own into the plans submitted. The experience of experts in this line is worth a great deal because they know the advantages and disadvantages of various plans and types of fixtures now in use.

Special kinds of cases and display units are required for the different lines of merchandise handled. Long experience in the manufacture of drug store fixtures leads to special knowledge along this line so it is advisable to buy fixtures from concerns that specialize in the drug store fixture business.

Individual department furniture and supplies, as cigar cases, soda fountains, candy cases, etc., will be discussed in connection with the organization and selling methods in these departments.

Lighting Facilities—The problem of lighting show windows and the store itself, with artificial light, is not a simple one if pleasing effects are desired.

A good show window and a fine display, well arranged, can be greatly lessened in value by lack of attention to proper illumination. Furthermore, glaring light from badly placed fixtures inside the store is not conducive to the comfort of a customer and will not tend to prolong his inspection or conversation regarding merchandise.

Engineers from the larger electric lamp manufacturing companies will gladly furnish lay-outs for the proper lighting of the storeroom and windows. These engineers will make such layouts without charge, and if the pharmacist will listen to their helpful suggestions, he will obtain much valuable information.

In the selection of lighting fixtures and the placing of sources of light one must remember that these should be entirely subordinated to the goods to be shown and sold. This is also true of other store fixtures. It is of no value to the pharmacist to have the greatest impression made upon the customer by the

intense illumination in his store or the beauty and elaborateness of his fixtures. The object of a lighting system should be to illuminate the store and merchandise adequately so that favorable impressions of these rather than of the fixtures, shall remain with the customer.

After nightfall, if the store is illuminated with diffused light, and all sources of light are out of the range of vision, the effect will be most pleasing and the whole interior can be taken in at a glance. The ceiling will have a "raised" appearance. Signs, price cards and departments will be readily distinguished and whatever artistic lines the general layout may possess will be accentuated.

Direct lights or bright bowls produce exactly opposite effects. The attention of the customer will be concentrated on the fixtures and as these are not for sale, in most instances, there is just that much loss of interest in the things which really are for sale.

It is much easier to plan the lighting system with the store than to make it an after-thought.

A properly planned lighting system should accomplish the following results:

1. Create favorable publicity through its pleasing impression on the customer, without making him realize that the lighting is the cause of the good impression.
2. Eliminate sharp, annoying, disagreeable shadows without destroying the necessary shaded areas which are required for proper contrasts.
3. Eliminate excessive cost of wiring and current.
4. Cut depreciation to the minimum. When the right kind of fixtures are selected, practically the only actual depreciation occurs in the lamps used.

The consensus of opinion among lighting experts seems to be in favor of indirect or concealed lights. The 200 watt color lamps or 300 watt "daylight lamps"—a light which resembles natural daylight in color quality—are suggested for good effects.

The space between the lighting units should not greatly exceed ten feet. The lamps should be properly shaded and both shades and reflectors should be of dense white glass rather than of colored or frosted glass. Shades should surround or enclose the lamps. Shades and lamps should be cleaned frequently. For uniform illumination in stores over 16 feet wide, it is well to have two rows of lights. In stores with 12 to 14 foot ceilings, lights should be mounted not less than 10 feet from the floor. Walls and ceilings should be painted a light color and have a mat finish so as to prevent reflections. The effectiveness of a lighting system is, of course, greatly influenced by the amount of light reflected from walls and ceilings.

Various devices can be purchased for securing extraordinary lighting effects in display windows. The window may be considered as a miniature stage with the passersby as the audience. Whatever lighting effects are pleasing on the stage will probably be relatively so in a show window.

In stores, catering to transient trade, where the windows are of prime importance, the window dressers often produce beautiful effects by adapting certain stage devices in their schemes of illumination. In the smaller stores this can be done in a limited way and creates much favorable comment.

Both in window and in show case lighting it is always advisable to have the source of light in front of the goods displayed. This avoids undesirable shadows. Lighting units should be placed in the upper front part of windows. Small lamps are preferable to one large unit here in order to have greater diffusion. By varying the intensity of light at either end of the window, different effects may be obtained. Footlighting is used in show windows to some extent but is

not satisfactory in all cases and always requires some overhead light to cut shadows. Except under special conditions lamps should not be placed in the middle of the show window ceiling, as this causes the front of the goods displayed in the foreground to be in shadow. Lamps so placed cannot be concealed effectively. This is another disadvantage.

It is not wise to place a lamp directly outside of the window. The glare is very bad and while it illuminates the sidewalk, the window will fail to "stand out" and the goods in the window will not be lighted effectively. Such a light may attract attention but, on the whole, the impression of the window will be unfavorable. Colored lighting effects do not work out successfully on dark backgrounds.

Lights and reflectors at the top and front of show windows are now most often concealed either by painted signs or by short curtains known as valances.

Good valances are very ornamental and lend to the store an artistic appearance which cannot be supplied in any other way. The initials or trademark or full name of the proprietor are frequently worked into window draperies giving an air of exclusiveness and individuality to the store front. It is customary to allow 2¼ to 2½ inches for every foot of window height, measuring from sidewalk to transom bar or point at which valance will hang. Thus a window measuring 10 feet high from sidewalk to transom bar will require a valance finished to a depth of 22 to 25 inches overall.

Every storekeeper has experienced difficulty from reflections in the plate glass of his window. These may be of the sky, opposite buildings or passing objects. Under certain conditions they are so severe as to prevent the merchandise being visible. There has been no entirely satisfactory method developed as yet to overcome these reflections. Provision of suitable awnings for some situations partially solves the matter. A patented design of curved plate glass will entirely eliminate the trouble; however, this is quite costly, detracts from the general appearance of the window, particularly at night, and uses valuable space. Artificial illumination of the show window during the daytime is often attempted as a solution. Its effectiveness depends on local conditions and it has serious limitations, chief among which is the expense of the great amount of electric current used.

In show case lighting it is advisable to avoid, as far as possible, casting reflections of the tops of glass show cases. This cannot be avoided entirely but, by careful planning, can be kept to a minimum. In the cases themselves the lights should be concealed in the corners and the light thrown directly on the product, away from the eyes of the prospective purchaser so that the lights will not drive the eyes away from the case, but will lead the vision easily into it, and allow it to rest with comfort upon the product. By careful observance of these principles, by keeping the lights in the cases scrupulously clean, and replacing the units which have burned out, a store may add materially to its public appeal.

Floors and Floor Coverings—The floors in old stores are not infrequently unsightly. When new fixtures are installed the contrast makes them appear even more so. The ordinary method of repairing a floor in an old building is to lay a new hardwood maple floor of good kiln dried stock, so that it will not open up in cracks. In new buildings the floors are generally of good quality and need no special attention.

Various methods and preparations for preserving wood floors are in use. The preservative preparations, applied to the floors are usually liquids which fill the pores, cement the wood fibers and make it impervious to water, thus

preventing decay and splintering. Such treatment of wood floors also makes them more sanitary.

Various plastic coverings for wood floors are on the market. Most of these are comparatively new and it is wise to inspect a store where the covering has been in use for some time to note the effect and also inquire as to the satisfaction given, before deciding on any special one.

Linoleum and similar compositions of various qualities and kinds have long been used as floor coverings and have given general satisfaction. The use of carpets and rugs is now rare. Mosaic tile and stone floors are in use to some extent with corrugated rubber or carpet runners to relieve the extreme hardness and cold appearance.

Show Cases—The first show cases that had any extended use were small counter display cases a few inches high and frequently built with German silver corner moldings. These were placed on top of wooden counters or cast iron legs in the old-fashioned stores. One still finds occasional small cases of this type for the display of odd articles but more modern types are now in general use.

For display purposes, plate glass is far superior to other forms of glass. It should not be confused with window glass, a much less expensive product.

The difference between the two materials is clearly set out by the Bureau of Standards in the United States Government Master Specifications for Flat Glass for Glazing Purposes:

"*Plate Glass*—Transparent, flat, relatively thin glass having plane polished surfaces and showing no distortion of vision when viewing objects through it at any angle. Plate glass is made at present by rolling large sheets periodically or by rolling a continuous sheet. The sheets are then ground and polished.

"*Clear Window Glass*—Transparent, relatively thin, flat glass, having glossy, fire finished, apparently plane and smooth surfaces, but having a characteristic waviness of surface which is visible when viewed at an acute angle or by reflected light. Clear window glass is made at present by hand blowing, or by machine blowing and drawing into cylinders and flattening or by drawing directly into a sheet, the surface finish being that obtained during the drawing process."

An additional element of importance in getting the specified material, beside the difference in price of market value, is the fact that at least some of the companies who insure plate glass store fronts have declined to issue policies covering windows glazed with other materials than genuine plate glass.

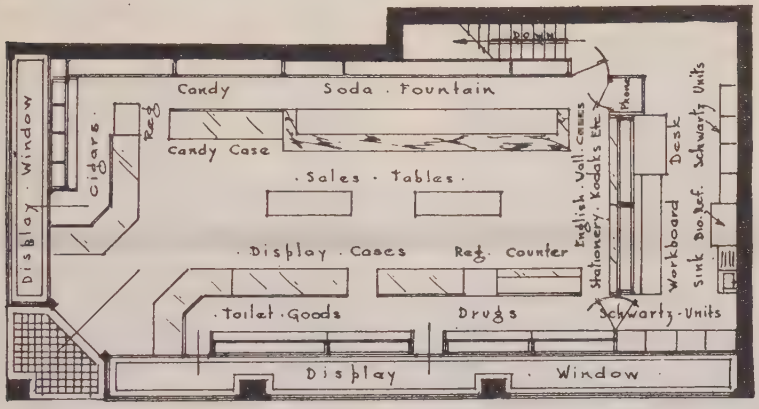
Full height cases made entirely of plate glass and bolted or cemented together with bases of wood or marble are the prevailing style at present. A point to keep in mind, however, is that the insurance companies in insuring the all plate glass type of show case—that is the type of case in which the plate glass corners are bolted or cemented together—base their insurance on the fact that 90 out of 100 such show cases have a breakage of some sort on it within a year.

Some manufacturers do not make the all plate glass type of case for that very reason, but make a type of case that appears to be all plate glass from the front but has enough of a wood frame end so that breakage has been reduced to a minimum. Furthermore, there is no display lost by having this light wood frame, as it merely provides a division between displays that accentuate the display. And again, in a line of show cases, the ends can be butted together tightly, thus making a more orderly, a more sanitary arrangement than the all plate type of case, where there is a space of 1½ to 2 inches between the actual glass ends of the case. An improvement on the wood or marble base, which

allows no foot room for customers standing close to the case, is the receding type of base and the leg base. The latter is the most sanitary as it permits sweeping and cleaning the floor under the case. Lighting of show cases has been dicussed in a previous section.

Various movable display units are now available, both of wood and metal

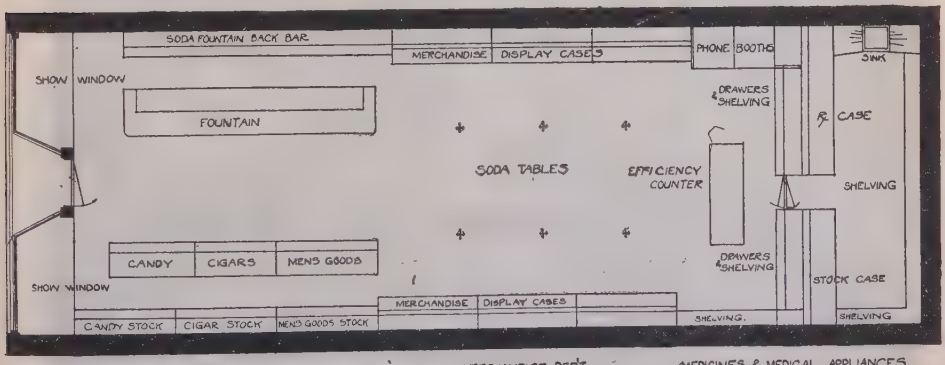
FIG. 442



A drug store layout by the Wilmarth Showcase Company

construction. These have an advantage in that they may be placed wherever there is room, either to supplement the display of a particular department or for making available something special or new. The disadvantage is that they are

FIG. 443



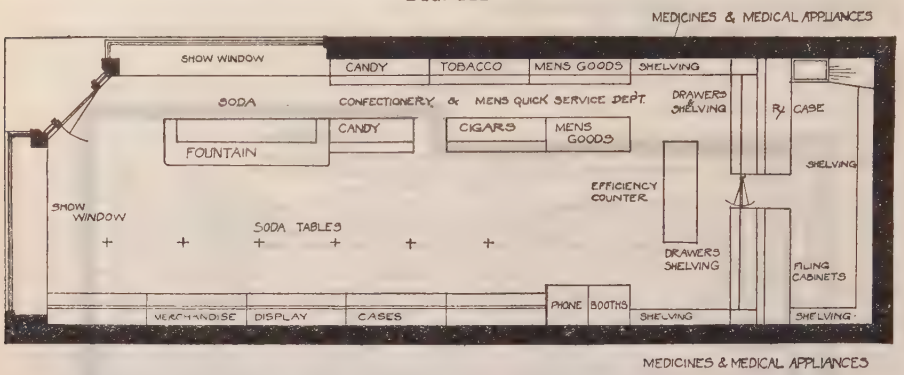
A center door layout by the W. B. McLean Manufacturing Company

not covered and merchandise may become dusty and shopworn or may be stolen readily.

Fig. 442 represents a store layout as planned by the Wilmarth Showcase Company, Grand Rapids, Mich. Note the space for display windows at the front and along one entire side of the store. Cigar and candy departments are close together and the soda fountain immediately adjoins the candy department, differing from the usual layout which places the soda fountain close to the entrance of the store. In this plan the toilet goods department shares

with the cigar counter, the advantage of attracting first attention upon entering the store. Other features follow more or less conventional lines.

FIG. 444



A corner door layout by the W. B. McLean Manufacturing Company

Fig. 443—A layout supplied by W. B. McLean Manufacturing Company, Pittsburgh, Pa., pictures a store with a center door and window display space on either side. Here the fountain occupies one side of the entrance while candy,

FIG. 445

A typical Liggett drug store

cigars and commodities for men, in the order named, are opposite the fountain. Merchandise display cases occupy both sides of the store in the central portion and the drug department is in the rear.

Fig. 444—Another layout supplied by the Wm. B. McLean Manufacturing

Company which represents a corner entrance with show windows at the front and part of the way on one side. There are no counters along one side at all,

Fig. 446

The front of the Hynson, Wescott and Dunning Pharmacy

display cases taking their place and making room for soda tables in the center. The opposite side provides for installation of the soda fountain, cases for candy, cigars, and merchandise for men, in the order named, with drugs at the rear.

Fig. 445—A typical store of the Liggett chain. Note the soda fountain arranged partly with seats and partly for standing room along a greater part of one side of the store, while on the opposite side, cigars, candy and toilet articles, are arranged in the order named, and the drug department is in the rear. In the center, are special display cases and tables providing striking dis-

Fig. 447

The Powers and Reynolds Pharmacy

plays, some of which must be passed no matter what department of the store a customer is patronizing.

Figs. 440 and 446 show the front of the pharmacy of Hynson, Wescott and Dunning, Baltimore, Md. Note the professional atmosphere and the dignified displays of pharmaceutical and toilet supplies. The absence of ordinary merchandising displays with the comfortable chairs and the writing table carry one back to the period when pharmacies were places where people came to have prescriptions compounded very much as they visited the physician for the diagnosis of their ills.

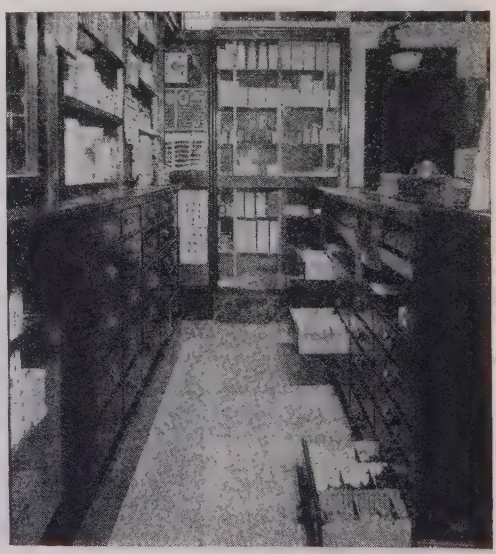
Fig. 448

The pharmacy of Rees C. Roberts

Fig. 447 illustrates a well arranged store. Note that soda fountain customers are within sight of practically all departments. The display wall cases near the tables doubtless act as salesmen very often. This is the Powers and Reynolds store of Philadelphia and was fitted by the Wm. B. McLean Manufacturing Company.

Figs. 448 to 452 illustrate the store of Rees C. Roberts in the Chalfonte Hotel Building, Atlantic City, N. J. Fig. 449 shows a very efficient arrangement behind the counter which enables the clerk to work rapidly and without much lost motion. Note the compact wrapping counter in which space immediately under the top is used for storing rolls of wrapping paper and the string at the end of the counter. Drawers with their various compartments containing merchandise in frequent demand, help the general efficiency plan.

Fig. 449



Combination of drug and wrapping counter

Fig. 450 is an illustration of how the proximity of one department to another frequently adds to the day's receipts. The cigar customer is here shown in the act of becoming a candy customer as well. Incidentally, the display case is one of the newer type, making merchandise visible at one glance.

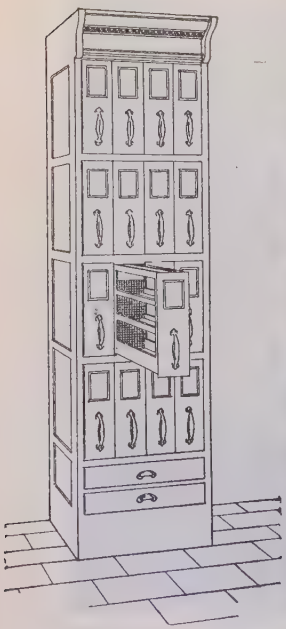
Fig. 451 shows a corner of the merchandising department in which the wall case and display case are combined for very efficient and effective service.

Fig. 456

The Schwartz System in the prescription department

Fig. 452 presents a view of soda booths and tables so arranged as to keep various items of merchandise continuously before those who are sitting at the tables. Note the styles of tables and chairs along the sides and the booth arrangement in the center. This store was planned and furnished by the Wm. B. McLean Manufacturing Company.

Fig. 457



Sectional case for small packages

Fig. 458

Typical prescription case

Fig. 453 represents part of the Adamson Drug Company's Pharmacy in Los Angeles, California, and indicates another combination of wall and show case which is very effective in a large store. This store was planned and furnished by the Wilmarth Fixture Company.

Fig. 454 is a view of the prescription department in the Hynson, Wescott and Dunning Pharmacy, Baltimore, Md.

A good method of conserving space in the prescription room is illustrated by the pharmacy of Fred Howard, Lowell, Mass., which is shown in Fig. 455. All containers are under cover in the Schwartz sectional cases. This makes for orderliness and cleanliness. Fig. 456 illustrates a similar arrangement. A similar type of case is illustrated in Fig. 457.

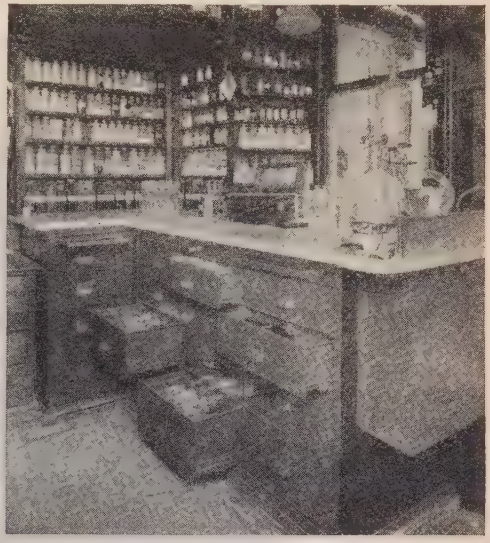
A typical prescription case and work counter for a store of moderate size is shown in Fig. 458.

Figs. 459, 460, and 461 are from the prescription department of the pharmacy of Frank E. Morgan and Sons, in Philadelphia. They show the application of steel furniture in prescription departments. The available space has been very ingeniously used through careful planning. The layout was planned by the Wilkinson Equipment Company of Philadelphia, and the fixtures were manufactured by the Watson Steel Furniture Company, Jamestown, N. Y.

Fig. 459 shows the sliding shelves equipped with plate glass tops which are used for mixing ointments and similiar operations, and the bottle drawers which are all equipped with roller bearing suspensions and subdivided with adjustable partitions for different size bottles.

Fig. 460 shows the method of storing prescription books. The shelves here are equipped with rollers and are adjustable for any size of book. This particular piece of equipment solves the problem of handling prescriptions in book form satisfactorily.

Fig. 459



Steel furniture in the prescription department of Frank E. Morgan and Sons

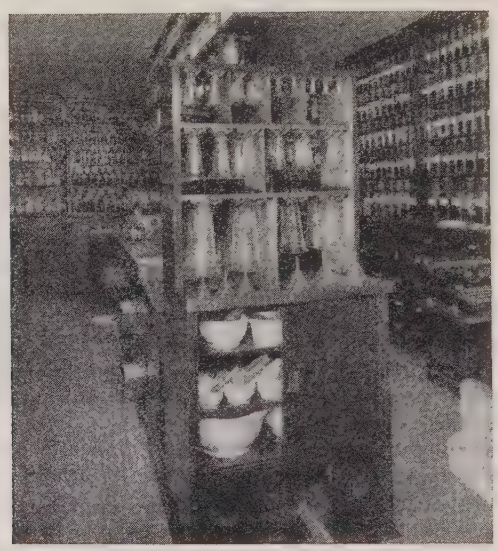
Fig. 460

Prescription book case and steel furniture used by Frank E. Morgan and Sons

Fig. 461 shows a graduate rack which is constructed of bronze. The graduates are held in position in such form that they may drain and the shelves are sloped to permit the water to run off into the sink. Throughout this construction the steel is finished in baked enamel while the tops of cases are of marble.

Every prescription department should give careful consideration to the facilities for cleaning apparatus since this often reflects the true ideals of the

FIG. 461



Bronze graduate rack, mortar closet and sink in the pharmacy of Frank E. Morgan and Sons

store. A well-arranged sink and drain board, with modern sanitary plumbing, and an adequate stock of these elementary but essential parts of the equipment, namely, the graduates and mortars, will do much to impress the visiting physician with the standards of the prescription department.

A draining rack over the sink, made by fastening round wooden sticks at an angle, in regular rows in a board against the wall, is very convenient for drying graduates, bottles, flasks, test tubes, etc. Such an equipment is inexpensive and generally satisfactory.

CHAPTER LXXXII

THE SERVICE AND COMMODITIES OFFERED FOR SALE

EVERY pharmacy has two things to offer the public. (a) Professional service, and (b) commodities. The variety of the offerings under each of these classifications are greater in pharmacy than in any other business or profession. Under the heading of professional service may be classified such individual items as prescription filling, the giving of information covering a wide field but specializing on health matters, emergency service such as every pharmacy is called upon to supply more or less frequently, and special service which takes the form of personal courtesies, such as supplying postage stamps, extending credit for goods purchased, and similar matters.

The supplying of pharmaceutical commodities, which originally centered around drugs and toilet preparations, has in recent years expanded to include many items that have not even a remote connection with pharmacy in the professional sense of that term. These commodities include, in addition to simple drugs and chemicals, various proprietary products, hospital supplies, candy, stationery, cigars and tobacco, rubber goods, bristle goods, toilet articles and perfumes, soda and allied items branching out in some cases into articles of food customarily obtained only in restaurants or food stores. More recently there has been added to the list a variety of novelty goods varying in their character according to the location of the establishment and the needs and desires of the immediate neighborhood.

As has been repeatedly brought out in these pages, ultimate success is greatest in those pharmacies which do not entirely submerge their professional background. As long as prescription and health service are continued as the main factors and the public is made to feel that these are of primary consideration, there is justification for holding out the pharmacy as a superior retail establishment even for certain kinds of general merchandise. Once this professional background is entirely removed or so subordinated as to be unrecognizable there is nothing about the store which makes it superior to the ordinary merchandising emporium. There is no particular objection in the more commercialized type of drug store, to the placing of the drug and prescription departments to the rear, provided these are arranged as a separate section and are always in charge of competent people. To maintain this atmosphere there, however, must always be that impression made upon the public that the main service of the store is the proper compounding of prescriptions and the insuring of an adequate supply of pharmaceutical products of high standard and reliability. When the public sense this professional atmosphere in a pharmacy they will automatically have a feeling of confidence in the conduct of other parts of the store. It cannot be expected, however, that this peculiar confidence will exist where there is a complete submersion of the pharmaceutical department, even though all other departments are run with the highest efficiency.

What Constitutes a Retail Drug Business?—Analysis of the sales of many hundreds of drug stores the country over, by competent observers, has established approximate percentage figures to indicate the make-up of the average retail drug business of today. These percentage figures are as follows:

Prescriptions, about 10 per cent
Proprietary medicines, about 22 per cent
Toilet Articles, about 10 per cent
Rubber goods, about 3 per cent
Confectionery, about 5 per cent
Cigars and tobacco, about 8 per cent
Soda, about 14 per cent
Miscellaneous items, including sundries and unspecified merchandise, about 28 per cent

These figures will probably not fit any single store and there are many cases where the prescription business constitutes more than 10 per cent of the total. However, these figures are based on the facts as gathered from a variety of stores.

It would be impossible to give detailed information on the many items that make up the stock of any modern individual pharmacy, so they will be considered in the main groups tabulated above and their subdivisions. The principles of buying, storing, pricing, and handling the stock of a pharmacy are, in the main, identical for all groups but where there are special considerations these will be brought out under the individual groupings.

Buying Merchandise

The Buyer—Successful merchandising depends to a very large extent on judicious buying. No matter how well the sales work is organized, profits are not what they should be unless goods are bought at the right price. Experience is a great asset in this phase of business as in all others. There are always some individuals who have a natural bent for making shrewd deals and the knack of taking advantage of opportunities. A study of market conditions and a knowledge of past performances in the various markets, with an application of the law of averages, must be a part of the mental process of a successful buyer. In large establishments the buyer is usually spoken of as the "purchasing agent" and he maintains a department, with assistants, whose business it is to follow the markets and to tabulate information as to requirements and sources of supply, so that every advantage as to price, quality, and delivery may be assured the purchaser.

In a retail pharmacy the buyer is usually the proprietor or manager although the purchasing of stock may be delegated to a subordinate who has shown particular ability along that line. One advantage in making an assistant the buyer is that the time of the proprietor or manager is conserved and if there are special deals, subject to high pressure salesmanship, and involving more or less risk, the buyer can obtain all of the information and then submit it to the head of the organization for a final decision. Whoever is charged with the duty of purchasing supplies should, of course, maintain constant contact with the various departments for which supplies are bought, as the people who do the selling know what is in demand and are likely to be in a position to give good judgment on the possibilities of selling something new or have the information concerning the quantities of standard merchandise required within a given time.

A knowledge of the buying capacity and of the demands of the community are essential to intelligent buying. Often the most expensive grades of merchandise may not be salable or the reverse may be true. The more all around information the buyer possesses the more intelligent will be his decisions as to what is and what is not a good purchase. It is not well for the buyer to attempt to carry in his mind all the information on which he depends for his judgment. With more than 3000 items to consider this is practically impossible. Records of purchases, with quantity and price, should be kept even in the smallest stores. A simple method is to keep an alphabetical card index of every commodity bought. If the card is made out at the time the goods are bought it does not involve much trouble. The information to be recorded consists of the name of the item, the date of purchase, the quantity bought, the price, and the source. A specimen card is printed herewith (see Fig. 462). The first entry indicates that 25 pounds of citric acid were purchased at 60 cents per pound

from R. W. P. Company on February 25, 1925, and so on down the line. Let us assume, for sake of example, that a chemical salesman came to this buyer with a special price on citric acid in 50 pound lots about the end of June, 1926. Naturally he would be forced to decide whether it would pay to tie up the money required for this purchase. Without a record of previous purchases he would depend almost entirely upon a guess, but with a record such as the above his decision can be based on facts and will therefore be less apt to result in an ultimate loss rather than a profit, if the deal is entered into. The card record shows that the first 25 pounds of citric acid lasted about three months. The next 25 pounds lasted about two months. Then 50 pounds were bought and that lasted five months. The next 25 pounds lasted a little more than two months. This indicates a total consumption of 150 pounds in about thirteen months or about 12 pounds per month. Fifty pounds should therefore last about four months. But it should also be noticed that more was sold in June and July than

FIG. 462

CITRIC ACID

Date	Amount	Price	Source
2–25–25	25 lb.	60¢ per lb.	R. W. P. Co.
6–2–25	25 lb.	65¢ per lb.	R. W. P. Co.
8–2–25	50 lb.	55¢ per lb.	R. W. P. Co.
1–5–26	25 lb.	60¢ per lb.	R. W. P. Co.
3–12–26	25 lb.	62¢ per lb.	R. W. P. Co.
6–30–26	50 lb.	52¢ per lb.	R. W. P. Co.

Record of purchases

in the fall and winter months. Therefore a special price on 50 pounds in June would be a more attractive proposition in this store than at another season, yet it is a question whether it would be wise to tie up the capital necessary to buy that quantity. The saving over the regular price will determine this. Having the purchasing record on hand when the salesman calls enables the buyer to decide intelligently whether the deal would be to his best interests and will prevent him from becoming merely the victim of a good sales talk. Such a card index takes up little room and becomes increasingly valuable as a buying guide. It also supplies information to those who do the buying in the absence of the regular buyers. The buyer should have access to recent price lists and to publications giving market prices and changes in these prices periodically. A monthly list is not of great value for articles that are subject to much fluctuation. Weekly trade journals and daily publications such as the *Journal of Commerce* and the *New York Commercial* should be subscribed to in order to keep an accurate watch on the trend of the market.

Methods of Buying—In the larger centers where there are wholesale houses it is now customary for such concerns to telephone periodically to their customers for orders. In the cities, daily calls are made. In outlying territories,

the calls may only come two or three times a week. These telephone calls are intended to take care of the routine orders. Special deals and orders that require conferences with sales representatives are taken care of by the traveling salesmen of wholesale houses. In many cases orders are mailed to the wholesale house at regular periods, so calculated, as to make sure of the receipt of the goods at a given time.

It is a sign of inefficiency for the pharmacist to be out of any item that is regularly called for in the average drug store and it is one of the most difficult problems of store management to prevent this happening. It is an established rule in most stores that when any clerk observes the stock of an item he is selling to be low that he shall immediately write the name of this item in the "want book". Very often the "want book" is in the rear of the store and the clerk has several customers to serve so he postpones writing the item into the "want book" and later forgets it entirely. The best method of overcoming this is to have several "want books" at convenient places and insist that the item be entered at the time the sale is made no matter how busy the clerk may be. It may happen that the same item will be entered in two or three "want books", if there are that many about the store, but it is much better for the buyer to assemble the books and check up duplications than to be out of stock when an item is called for. "Want books" are supplied by various wholesalers and manufacturers or a standard form of book may be devised for the individual store. An ordinary blank book will answer the purpose.

If it is customary to give orders over the telephone, the buyer should have his order ready at the time the telephone call is usually made and not have to depend on snap judgment when the call comes. It is important that the ordering shall be done by one person and that items ordered be checked by a distinguishing mark in the "want book", to avoid duplicating orders.

While it represents some extra work, the only satisfactory method of keeping track of goods ordered is to make out the order in duplicate on a regular form provided for that purpose. Various wholesale houses and manufacturing concerns furnish order books with carbon paper so that the druggist can retain a copy of the order sent in. However, it pays to have order forms printed for the store to suit the methods of the management. A carbon copy duplicate of all orders should be retained in the file of the store so that when goods are received there is something at hand against which the invoice may be checked. It is unsatisfactory to depend on the "want book" for this purpose although some pharmacists simply write the quantity ordered opposite the name of the item in the "want book" and cross it off when it is received. This makes it difficult to read the item in case it is necessary to check it back at a later date. For all around satisfaction in ordering merchandise there is nothing better than the individual order form made out in duplicate. The original is sent to the wholesale or manufacturing house, the duplicate is retained. If at any time it is desirable to determine whether or not certain goods were ordered, reference to the duplicate order will give the information. When the goods are received the invoice may be checked against the original order and all shorts are immediately revealed. When the bill for the goods comes in this can also be checked against the original order for quantities and for "shorts". In other words, instead of depending upon memory or the unsatisfactory record sometimes made in the "want book," but more often omitted, the buyer always has on hand a definite source of information upon which he can depend. It frequently happens that a wholesale house sends more or less of an item than has been ordered. This, of course, is revealed in the checking and should be immediately reported, unless the wholesaler's invoice indicates on their part a

knowledge of the change. It is of importance to report "overs" as well as "shorts", should these occur. In larger establishments, there are, of course, order departments and receiving departments, but in the ordinary store, this is taken care of by the regular force and does not take a great deal of time. It is also well, even in a small store, to have some single individual responsible for the checking of goods received, to approve all bills, and to order all items needed.

Whenever it is possible the buyer should take advantage of the opportunity to purchase materials directly from displayed stocks. This applies particularly to the buying of merchandise other than standard pharmaceuticals and chemicals. Regular visits to the centers of supply, whether made in the same city or in neighboring communities, are very helpful. They not only give the buyer an opportunity to see what is new but supply contacts with manufacturing and wholesale concerns which result in a fresh viewpoint, greater information about various items, and all the advantages that accrue from personal contact with individuals in the concerns doing business with the retailer. The cost of occasional trips to the buying centers is amply repaid by the advantages just referred to.

It is a good plan when making out orders to prepare a third carbon copy of the items ordered but to omit the quantities and then insist that the person unpacking the goods insert the quantity received. This list is then compared with the copy of the original order and shortages or over-shipments are noticed immediately. It will also cause greater care in the checking of the goods by the receiver.

When goods have been bought and received, a careful checking of the bills is necessary and each item should be priced in accordance with the cost and prevailing selling prices. It is routine practice in many organizations to have a receiving room of suitable size with a table upon which everything is placed as it is unpacked and upon which the articles are left until checked off and priced. The goods should then be stored properly. For this purpose there is usually provided a place where the excess stock may be carried, only a few packages being placed on sale. A feature of the Liggett store organization is the arrangement of the stock room into departments corresponding to the departments in the front of the store. The goods for each department are kept on shelves behind a locked door, the sections being divided off by heavy, rat-proof, wire screen, nailed on a frame. The stock is arranged on the shelf in the storeroom in the same order as in the store, so that it can be found readily.

An idea proposed and used by the late H. P. Hynson, in his stockroom was the utilization of wooden boxes of uniform length and depth, 5 feet by 3 feet, but of different widths. These boxes were laid upon their side to form a stack. If a low shelf was needed the narrow box was used. If the items required more height, a wider box was put in place. In this way an adjustable set of shelves was provided and also shelves which could be readily moved or rearranged. It is very convenient to have, posted on the outside, a list of the items contained in each bin or section, and an alphabetical list with a mark opposite each item to show just where it may be found on the stock shelves.

It is of prime importance that the stockroom should be dry, rat-proof, of average warmth, and well lighted, and it should also be kept free from dust; otherwise serious losses will occur through deterioration.

In some modern drug stores, the stockroom is eliminated entirely. As soon as merchandise has been checked it is placed in the store. This method has several important advantages. The fact that all the stock is in full view of the customers impresses them with the extent and variety of merchandise carried

by the store. It creates confidence and promotes "shopping". The store is less apt to be out of wanted items. Salespeople know they cannot depend upon a reserve supply in the basement, which may or may not be there. Time of customers and salespeople is saved because no time is lost looking for reserve stock.

Stock in the basement is also subject to serious losses through theft. The ashman, drayman, and many other strangers have ready access to stock there.

In marking goods, both the selling price and the cost should appear. The latter figure is written in code and is very convenient in taking inventory or referring to the cost in case of special allowances. Usually a word of ten letters or two words totalling ten letters are used to represent the figures from 0 to 9 as

1 2 3 4 5 6 7 8 9 0

PHARMOCIST and combinations of these letters are then employed to designate various cost figures. PT would represent 10; MT = 50; HM = 25 and so on. Crossed lines are also used to work out codes. By arranging 4 lines as in

FIG. 463

1	2	3
4	5	6
7	8	9

Pricing code

Fig. 463, and numbering as indicated, a code can be worked out using the diagrams made by the intersections to represent the figures 1 to 9 and 0 for zero. Thus ⌊ ⌋ would be 25; ⌊ ⌜ = 19; ⌜ ⌝ = 80; ⌊ ⌞ = 43. By starting the numbering in different corners or at other points various changes in the same code may be produced, as indicated in Fig. 464 below:

FIG. 464

3	2	1
6	5	4
9	8	7

1	4	7
2	5	8
3	6	9

6	1	7
5	2	8
4	3	9

Pricing codes

Pricing

One of the most important considerations in connection with successful merchandising of either service or commodities is the establishment of prices, reasonable enough to meet competition, but which will at the same time furnish an adequate profit. Nothing is more fallacious than the idea that everything charged above the cost of an item is profit. It is *gross margin* to be sure, but it is very far from being *net profit*. Inability to establish the cost of conducting a business, or its "overhead" accurately, and failure to include this figure in the "mark-up", has been the ruination of many a promising business.

The most recent figures on retail drug store operations and profits indicate that a common margin of gross profit is close to 34 per cent. This means that out of every dollar taken in over the counter 66 cents represents actual cost of the goods sold. The 34 cents left must pay for labor, rent, heat, light, and other expenses. In a well conducted business approximately 11 cents

of the 34 would go for clerk hire; 5 cents for rent and from 6 to 9 cents for light, heat, advertising, insurance, taxes, telephone and the many other incidental expenses that come up. This leaves from 9 to 12 cents actual profit which is spoken of as "net profit". Thus it can readily be seen that if the price on a $1.00 article is cut from 9 to 12 cents there is no net profit and if it is cut more than 12 cents there is an actual loss which must be made up in some other way if this actual loss is to be avoided. Of course it is true that there are some departments of the business which may yield a greater gross margin than 34 per cent but as conditions become more competitive these higher margins are gradually reduced and cannot always be depended upon to make good the losses elsewhere. Furthermore there are departments where the normal margin is far below 34 per cent. The point to be stressed at this juncture is that pricing of goods must be on the basis of their actual cost, plus the cost of doing business. Methods of arriving at the latter figure for any particular store will be found in the chapter on accounting but some of the factors involved will be discussed here.

It costs money to carry slow-moving merchandise in stock as can be demonstrated by checking up the profits on rapidly-moving items, comparing them with those on slow sellers. The "carrying charges" on the latter class of items increase the overhead expense of a store materially.

This is graphically illustrated in the following table published by the W. B. McLean Manufacturing Company:

Month	First cost	Selling cost	Carrying cost	Total cost	Sales price	Percentage of profit	Per cent of loss
First	$10.00	$2.36	$ .44	$12.80	$15.00	14⅔	
Second	10.00	2.36	.88	13.24	15.00	11⅔	
Third	10.00	2.36	1.32	13.68	15.00	9	
Fourth	10.00	2.36	1.76	14.12	15.00	5⅞	
Fifth	10.00	2.36	2.20	14.56	15.00	3	
Sixth	10.00	2.36	2.64	15.00	15.00	0	
Seventh	10.00	2.36	3.08	15.44	15.00		3
Eighth	10.00	2.36	3.52	15.88	15.00		5⅞
Ninth	10.00	2.36	3.96	16.32	15.00		9
Tenth	10.00	2.36	4.40	16.76	15.00		11⅔
Eleventh	10.00	2.36	4.84	17.20	15.00		14⅔
Twelfth	10.00	2.36	5.28	17.64	15.00		17⅔

The theory upon which this table is constructed is this. Suppose it is estimated that the expense of keeping $15.00 worth of merchandise in the store for one month is $.44. (This figure will vary for different stores, but it is believed to be an average.) That is to say, the value of the space occupied by the merchandise represented by rent, also the insurance, depreciation, heat and light used by or for this merchandise is $.44 a month, and allowance for it is made in the selling price. This $.44 is entirely distinct from the $2.36 selling cost. This $2.36 covers clerk hire, expenses of wrapping, delivery, advertising, etc., which occur only when the merchandise is sold. *The $.44 is incurred monthly regardless of whether or not the merchandise is sold.* Thus, if the merchandise is not sold for two months there is a carrying charge of $.88. Because only $.44 has been allowed for, the additional $.44 must come out of the expected net profit, which accordingly is reduced from 14⅔ per cent to 11⅔ per cent. Three months' carrying charges are three times $.44 or $1.32, thus reducing expected profits from 14⅔ per cent to 9 per cent. As the table shows, the merchandise, if it is kept long enough, is sold at an actual loss.

Turnover or Stock-turn

"Turnover" refers to the number of times a year a merchant turns his capital. If his inventory is $10,000 and the total purchases of goods amounted to $50,000 for the year he has turned his stock 5 times.

The Harvard Bureau of Business Research, several years ago, investigated 187 retail drug stores. The stock turnover in these stores averaged only 2.3. On the other hand, to show that more turnovers are entirely practicable under skilful management, the Liggett stores in 1924 report the following turnovers in the several departments. The figures are the ratio between the cost of goods and the sale price.

Drug department	8 turnovers
Package medicines	11 turnovers
Fancy Goods—(perfumes, etc.)	10 turnovers
Hospital supplies	8 turnovers
Cigars	13 turnovers
Candy	14 turnovers
Soda	50 turnovers

Immediately one is impressed by the importance of this phase of management and it must be recognized that the greater the number of "turnovers" the higher the proportional per cent of profit.

Expenses must include salary and rent. Some business men delude themselves into thinking that they evade certain overhead charges because they own the store building and do not allow for any salary for themselves in their accounting. To be sure they do not actually lose any more cash by such accounting methods than if they did take these items into consideration and ignored their resulting low net profits but it should be plain that if they owned a building which they did not personally occupy they would expect a rental and if they worked for somebody else they would expect to draw a salary. Modern business methods demand inclusion of rental and proprietor's salary in the overhead expense. It is also worthy of note that failure to include a rental charge and salary of the proprietor in the cost of doing business naturally increases the income tax on the business. If the proprietor should become incapacitated and be compelled to employ a substitute the salary of the substitute would immediately add a heavy load to the overhead unless this item had been carried previously. The question of how much salary a proprietor should draw may best be answered by determining what his services would be worth in another establishment or what it would cost to replace him. The proprietor's salary should not be excessive as he can depend on the net profit of the business for extra income, but it should be adequate for his current needs.

Cash Discounts

The business man should strive to secure for himself, as soon as possible, a position in which he will be able to discount his bills. The 1 per cent and 2 per cent and sometimes more, allowed for cash in ten days, amounts to a great deal in a twelve month period. It sometimes represents the difference between just "making ends meet" and a comfortable margin of profit. Cash discounts and trade discounts on quantity purchases are two different things as will be seen a little later in this discussion. The former are desirable, the latter may or may not prove advantageous.

The following table indicates the value of cash discounts:

½	per cent in 10 days, net	30	days is equal to	9 per cent a year
1	per cent in 10 days, net	30	days is equal to	18 per cent a year
1½	per cent in 10 days, net	30	days is equal to	27 per cent a year
2	per cent in 10 days, net	30	days is equal to	36 per cent a year
2	per cent in 10 days, net	60	days is equal to	14 per cent a year
2	per cent in 30 days, net	60	days is equal to	24 per cent a year
2	per cent in 30 days, net	120	days is equal to	8 per cent a year
3	per cent in 10 days, net	120	days is equal to	10 per cent a year
3	per cent in 10 days, net	60	days is equal to	21 per cent a year
3	per cent in 30 days, net	60	days is equal to	36 per cent a year

Relation of First Costs, Overheads and Profits to Sales

In discussing the general principles of business in an earlier chapter, the subject of sales being made the basis for business analysis, was briefly discussed. It seems difficult to make it clear to some who are in business that the modern basis for calculating profits, expenses, etc., is upon the amount of sales, considering the latter as one hundred per cent.

This, of course, is contrary to the method of calculating profit taught in common schools and explains the frequent discussions on this point and the difficulty of making it understood. By the older method a hairbrush bought at 60 cents and sold for 90 cents would have been considered as yielding the proprietor 50 per cent profit (using the cost as 100 per cent); but by the accepted method of estimating profit and in which the sale price of 90 cents is taken as 100 per cent, it becomes evident that the gross profit of 30 cents is only 33⅓ per cent, instead of 50 per cent. Of course, no more money is made in either case but it is very important at the outset to understand the basis of the "profit and loss" statement.

The reason for the universal adoption of this policy is found in the fact that the amount of sales is readily available and may be used daily as the basis of comparison with the business of other days. It would not be easy, in fact practically impossible without an enormous amount of labor, involving an inventory, to know the cost of the goods sold on any one day.

The following table shows the per cent of profit on cost and on selling price:

5	per cent added to cost is	4¾	per cent profit on the selling price
7½	per cent added to cost is	7	per cent profit on the selling price
10	per cent added to cost is	9	per cent profit on the selling price
12½	per cent added to cost is	11⅛	per cent profit on the selling price
15	per cent added to cost is	13	per cent profit on the selling price
16⅔	per cent added to cost is	15¼	per cent profit on the selling price
17½	per cent added to cost is	15	per cent profit on the selling price
20	per cent added to cost is	16⅔	per cent profit on the selling price
25	per cent added to cost is	20	per cent profit on the selling price
30	per cent added to cost is	23	per cent profit on the selling price
33⅓	per cent added to cost is	25	per cent profit on the selling price
35	per cent added to cost is	26	per cent profit on the selling price
37½	per cent added to cost is	27¼	per cent profit on the selling price
40	per cent added to cost is	28½	per cent profit on the selling price
45	per cent added to cost is	31	per cent profit on the selling price
50	per cent added to cost is	33⅓	per cent profit on the selling price
60	per cent added to cost is	37½	per cent profit on the selling price
65	per cent added to cost is	39½	per cent profit on the selling price
66⅔	per cent added to cost is	40	per cent profit on the selling price
100	per cent added to cost is	50	per cent profit on the selling price

The Correct Way to Figure Profits

SHORT CUT TABLE FOR FINDING THE SELLING PRICE OF ANY ARTICLE

Cost to do business	NET PER CENT PROFIT DESIRED																				
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	20	25	30	35	40	50
15%	84	83	82	81	80	79	78	77	76	75	74	73	72	71	70	65	60	55	50	45	35
16%	83	82	81	80	79	78	77	76	75	74	73	72	71	70	69	64	59	54	49	44	34
17%	82	81	80	79	78	77	76	75	74	73	72	71	70	69	68	63	58	53	48	43	33
18%	81	80	79	78	77	76	75	74	73	72	71	70	69	68	67	62	57	52	47	42	32
19%	80	79	78	77	76	75	74	73	72	71	70	69	68	67	66	61	56	51	46	41	31
20%	79	78	77	76	75	74	73	72	71	70	69	68	67	66	65	60	55	50	45	40	30
21%	78	77	76	75	74	73	72	71	70	69	68	67	66	65	64	59	54	49	44	39	29
22%	77	76	75	74	73	72	71	70	69	68	67	66	65	64	63	58	53	48	43	38	28
23%	76	75	74	73	72	71	70	69	68	67	66	65	64	63	62	57	52	47	42	37	27
24%	75	74	73	72	71	70	69	68	67	66	65	64	63	62	61	56	51	46	41	36	26
25%	74	73	72	71	70	69	68	67	66	65	64	63	62	61	60	55	50	45	40	35	25

Rule—Divide the cost (invoice price with freight added) by the figure in the column of "net rate per cent profit desired" on the line with per cent it costs you to do business.

EXAMPLE:

If goods cost	$60.00
Freight	1.20
	$61.20

You desire to make a net profit of 5 per cent.
It costs you to do business 19 per cent.
Take the figures in column 5 on line with 19, which is 76.

76 | 61.2000 | $80.52 = the selling price
60 8
400
380
200
152

The percentage of cost of doing business and profit are figured on the selling price.

PROOF

Profit	5%
Cost	19%
Total	24%
Basis	100%
If Profit and Cost is	24%
Balance is	76% represents Cost

If 76% is Cost, or $61.20,
1% would be 76) 61.2000 (.8052
60 8
400
380
200
152

Now if 1% is .8052, 100% would be 100 times .8052

$80.52 Selling Price	100
.24 Profit and Cost	or 80.5200 Selling Price
32208	$80.52 Selling Price
16104	19.32 Profit
$19.3248 Profit	$61.20 Cost

SHORT CUT TABLE FOR FIGURING NET PROFITS

If your cost of doing business figured on sales is represented by one of these figures, and you mark your goods at one of these percentages above delivered cost, your percentage of net profit is represented by the figure at the junction of the two columns.

%	10%	11%	12%	13%	14%	15%	16%	17%	18%	19%	20%	21%	22%	23%	24%	25%
25	10	9	8	7	6	5	4	3	2	1	00	1 Loss	2 Loss	3 Loss	4 Loss	5 Loss
33⅓	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	00
40	18⅔	17⅓	16⅔	15⅔	14⅔	13⅓	12⅔	11⅔	10⅔	9⅔	8⅔	7⅔	6⅔	5⅔	4⅔	3⅔
50	23⅓	22⅓	21⅓	20⅓	19⅓	18⅓	17⅓	16⅓	15⅓	14⅓	13⅓	12⅓	11⅓	10⅓	9⅓	8⅓
60	27½	26½	25½	24½	23½	22½	21½	20½	19½	18½	17½	16½	15½	14½	13½	12½
75	32⅚	31⅙	30⅚	29⅙	28⅚	27⅚	26⅔	25⅚	24⅚	23⅔	22⅔	21⅔	20⅚	19⅔	18⅚	17⅔
100	40	39	38	37	36	35	34	33	32	31	30	29	28	27	26	25

Explanation—If your cost of doing business is 15 per cent of your gross sales and you mark a line at 25 per cent above cost, your net profit is 5 per cent on sales, as shown in the diagram. If your cost of doing business is 18 per cent and you mark a line at 60 per cent above cost, your net profit is 19½ per cent on sales.

Source of Supply

The Wholesale Druggist—If pharmacists were compelled to depend upon the individual manufacturers for their supplies of materials and merchandise, their business would be much more complicated than it is. Imagine for a moment upward of 3000 items being supplied to the individual retailer by the manufacturers. Not only would it mean hundreds of accounts to open, hundreds of checks to be written each month, hundreds of orders to be sent to as many concerns, but also a vast amount of correspondence and bookkeeping which would overwhelm the ordinary shopkeeper. Most of this burden is avoided by purchasing from wholesale druggists, often referred to as "jobbers". There are about 500 wholesale drug houses of one type or another in the United States and they are so located, geographically, as to place every drug store within easy reach of at least one of them. These wholesale houses carry vast stocks of items, sold in drug stores, estimated as between 30,000 and 40,000, and it is possible to buy practically everything from them or through them. This very greatly simplifies the problem of securing supplies for the retailer and also enables the wholesaler, who gives good service at reasonable prices, to do a very satisfactory business.

Coöperative Buying—In recent years there have sprung into existence various organizations of retailers organized for the purpose of buying rapidly selling products in sufficiently large quantities to obtain the wholesaler's discount and thus supply their members with these articles at reduced prices, thereby

increasing their profit by eliminating the "middleman". These organizations first took the form of buying clubs and more recently developed into coöperative wholesale houses. Under the coöperative scheme the retail druggists desiring the buying privilege purchase a specified number of shares of capital stock and agree to pay their bills weekly. In return they obtain an extra discount on the goods and a dividend on their capital stock if the company makes money. This amounts to a considerable saving in a year and there are some 15,000 or more druggists who are taking advantage of this opportunity. However the regular wholesale houses—usually referred to as the "Service Wholesalers"—enjoy the advantage of being able to sell a wider variety of goods and by extending credit for thirty days or more retain a large proportion of the retailers as customers.

As a rule, a retailer is not able to obtain all of the goods he needs from the coöperative concerns because some of the manufacturers refuse to sell to such houses. He is therefore obliged to buy from at least one service wholesaler or direct from certain manufacturers. Very often the service wholesaler is used merely as a convenience to supply those items which the retailer cannot obtain from his coöperative house. Much has been written and said as to the fairness of the coöperative method of obtaining supplies but it is clearly evident that the ideal method of supplying goods from manufacturing pharmacist to wholesale druggist and wholesale druggist to retail druggist and retailer to consumer is being violated by all groups. We have manufacturers selling direct to wholesalers and often to the public by mail or through establishments other than retail drug stores, thus ignoring the interests of their regular wholesale and retail distributors. We have wholesalers who manufacture or put up the same products as the firms for which they are selling agents and who sell to general stores as well as to pharmacists and in some cases directly to the public. It is therefore not surprising to find organizations of retailers also functioning as wholesalers and manufacturers. The various factors that enter into competition in the drug trade, such as price cutting, special manufacturers' discounts to large buyers, chain store organizations, etc., have brought about this confusion of interests and there is very little hope that the orderly, single procedure of supplying the consumer with all manufactured goods via wholesaler and retailer will ever become the only method of distribution in the drug business any more than in any other line, even though there are powerful influences at work to improve the present situation. A wide-awake retailer naturally takes advantage of all the opportunities offered him to obtain merchandise at a reasonable figure so that he may make a fair and honest profit. As long as he does not violate the code of ethics and the dictates of his own conscience he is within his rights and is using good business judgment in doing so. He should be fair in his dealings with all sources of supplies and bear in mind that unfair methods are often reciprocated.

Direct, Indirect, and Quantity Buying—Some retailers do a sufficiently large business to become preferred customers of certain manufacturers. This means that they obtain better discounts on direct purchases than are usually allowed by the manufacturer, in return for a guarantee to purchase a certain minimum volume of the manufacturer's goods within a given time. Arguments can be presented pro and con as to whether this procedure is better or not than indirect buying, through a wholesaler, as the goods are wanted or needed. What really decides the argument is whether there is more profit in a particular case when goods are bought from the wholesaler in the quantities needed from time to time and at the long price, or when a certain amount of capital is tied up for a period in order to obtain the special discount. Figures alone will tell the

story. Any pharmacist who has been in business for a sufficient time and has kept records can answer the question for himself by a simple calculation.

The same kind of a calculation is involved in determining whether it is profitable to make a quantity purchase of a fairly good-selling proprietary article. It is assumed that the sale of the article totals $10.00 per week and that the cost of this quantity is $6.00 with a net profit of $1.00, or 10 per cent on the selling price. In 25 weeks this would represent a net profit of $25.00 and the investment would at no time exceed $6.00. Should the manufacturer now offer an extra 10 per cent on a quantity purchase, which would be sufficient to last for 25 weeks, the net profit would rise to $1.60 per week.

The profit on 25 weeks sale of this item would total therefore $40.00 on an investment of $135.00 whereas in the other case the total profit is $25.00 on an investment of $6.00. It is apparent immediately that the total profit is greater in the case of buying in quantity, but that the percentage of profit is greater on the small quantity purchase. In the latter case, in 25 weeks, there is a profit of almost 30 per cent in the merchandise investment while in the other case it is over 400 per cent.

If the proprietor has limited capital it would be far better, of course, for him to buy in small quantities and distribute his purchases over as many items as possible in the hope that he could obtain a similar rate of return on them. On the other hand, if the proprietor has sufficient capital, the quantity purchase should prove attractive because of the greater total profit and the fact that a 30 per cent profit in 25 weeks is a far higher return than he probably could get by employing his surplus funds outside of his business.

But of course there would be many other factors to consider, as storage space, breakage, depreciation, danger of obsolescence, etc.

Extra discounts often sound attractive but when all the facts in the case are considered they may, in some instances, show an actual loss instead of a gain over the profit made on small purchases as needed and each proposition should be carefully analyzed before entering into it.

When a new line or even a single item in a line has been added to the commodities to be sold, care should be taken that the entire force of the store becomes acquainted with it. The buyer's foresight and judgment in providing salable merchandise may become a liability instead of an asset if there is no coöperation in selling or popularizing new goods that have real value. Knowledge of new things on the part of clerks must not be assumed. It must be imparted, for even the best clerks often fail to familiarize themselves with all new developments. Clerks coming from another store should be well schooled in the policies and methods of their new employers and it should be insisted that methods and policies that do not conform to the organization which they have joined must be discontinued.

If there has been an error in judgment or something unusual has arisen in marketing conditions to prevent the movement of merchandise as rapidly as anticipated, steps should be taken to move the goods by means of greater advertising, special sales, or instructions to the clerks to specialize on the sale of the overstocked item. Occasionally it is possible to resell overstocked goods to other dealers or to return them for credit to the source of supply.

Merchandise ordered in quantity on the representation of salesmen who are promoting a local advertising campaign, should be purchased with a written guarantee covering the salesman's promises and the proviso that payment be deferred until the advertising is in actual progress, or that the goods may be returned for full credit if the advertising does not materialize. Often pharma-

cists are induced to stock unknown goods on the strength of a salesman's promise which does not materialize, therefore this precaution must be taken.

It is unwise for a pharmacist to permit his store to be advertised as a source of any product unless he conscientiously feels that he can endorse it. The manufacturer's object in advertising a local pharmacy as the source of supply of his article is to capitalize the local reputation of the pharmacist for his own benefit. This is not objectionable if the product is a meritorious one, for in that case all parties, including the customer, are benefited. However, if the article is one of questionable value and origin the pharmacist is just as culpable as the manufacturer if he permits his name to be used publicly in connection with it. He cannot escape the accusation that the use of his name amounts to a virtual endorsement.

Prescription Service

The prescription department, located usually at the rear of the store, should be provided with sufficient room for the storage of materials and for a proper compounding space for more than one man. In stores with a high ceiling it may be found advisable to locate the prescription department on a balcony or mezzanine floor but this is not practical unless there is sufficient prescription work to keep one or more men constantly in the department. Stairways to such mezzanine floors may be built in circular form to wind around a post so as to consume little floor space. A dumb waiter can be arranged for service to this mezzanine floor from the wrapping counter.

The maintenance of sanitary conditions and scrupulous cleanliness are among the first requisites of proper care of a prescription department. Too often small, dirty, and unsanitary quarters are allotted to prescription work. Such conditions are not conducive to accuracy, neatness, or cleanliness in dispensing. The most progressive type of pharmacist will so arrange and equip his prescription department as to make it a show place. This is good advertising and inspires confidence. The prescription counter should not be used as a convenient place for unpacking boxes and cartons nor should this department be a loafing place for visitors to the store. There should be a gate of some kind between the store and the prescription department enabling the man in the prescription room to see the front of the store and yet acting as a barrier to those who have no business behind the counter. The gate should be so arranged as to make it possible for clerks to either see through or over it and avoid danger of collision with other clerks about to enter the prescription room. The gate should be at the side and not in the center in the ordinary establishment, although there are plans in which the center gate or opening to the prescription department is preferable.

Various arrangements can be made in supplying fixtures for the prescription department. Those who desire to hide the operator from the view of the customer can do so by selecting partitions to accomplish this end. On the other hand those who take pride in the appearance of their prescription department and wish to open it to the full view of the public can install low partitions which enable the prescription clerk to see the front of the store and at the same time give the customer a glimpse of the activities behind the counter.

There are advantages and disadvantages in having prescriptions filled in full view of the customer. If the customer sees the pharmacist looking for an item or hesitating over a prescription before pouring out the proper quantities of the ingredients, he is apt to become nervous or suspicious of the pharma-

cist's knowledge and ability to fill the prescription properly. The advantage is that it shows the customer there is nothing about prescription work that is secret or that the pharmacist is not willing to have his customer see. A number of stores doing the largest prescription business in their respective towns have their prescription departments so arranged as to give the customer a full view of where and how the prescriptions are compounded.

In most stores where prescription business amounts to anything the system of providing the customer with a duplicate check, bearing the number which is immediately attached to the prescription, is in vogue. This prevents errors in delivery and inspires confidence in the care exercised by the pharmacist. It conveys the impression of systematization, which is helpful.

It goes without saying that a stock of reliable, fresh, standardized drugs should be kept on hand and that proper storage facilities for various preparations should be provided. The refrigerator is a necessary fixture in a high class prescription department not only for the storage of biological products which are discussed fully in Part XIV but also for other pharmaceuticals which may be injured by high temperature or which appear better when kept cool. Provisions must also be made for keeping certain products dry and away from light, and others moist and warm. In this matter the pharmacist must depend upon his professional knowledge and in planning a prescription department, containers, shelf room, and location of the stock should be based on that knowledge. An index of the items on hand should be prepared and kept up to date. It is well to number the shelves and also to number the containers, in addition to labeling them, so that everything can be kept in place even though it is put away by a junior assistant. By means of a card index or a book in which the items are entered in alphabetical order they can be located readily by relief clerks unfamiliar with the stock or by the regular force. If one depends on a look around the shelves to find some odd tablet or pill it will often not be found and failure to find it at once leads to reordering or sending out for it when, as a matter of fact, the product may be somewhere on the shelves. With the many thousand items that make up a prescription stock it is no longer possible for even those with a good memory to remember the location of each item. The card index or a substitute for it is therefore at once economical and safe.

When marking the price of a chemical or drug product on the label in the prescription department it is customary to figure the cost per ounce and if the quantity is less than an ounce to figure it to the cost per grain. In this connection it should be remembered that the ounce used in purchasing is the avoirdupois ounce of 437½ grains and not the apothecaries ounce of 480 grains.

It is well to obtain the manufacturers' literature on all new products and to look it over carefully so as to be able to discuss the pharmacy and chemistry of the new products intelligently with the physician who may prescribe them. Such information can frequently be obtained most satisfactorily by a talk with the detail men or salesmen of the manufacturing houses. There should be someone instructed to obtain information particularly on new prescription products and, while it is essential that all members of the staff keep up their general information, it is inexcusable to have no one on the staff who knows about the latest therapeutic products. Fluctuations in the price of chemicals and pharmaceuticals should be watched carefully so that any increases in the prices of materials entering prescriptions are promptly noted. It should be the business of the buyer to follow at least one good market report regularly and keep those who have to do with pricing prescriptions informed of the changes.

Pharmaceutical Products

Under this heading come simple drugs and chemicals, hospital supplies, proprietary products, including lines of "home remedies" manufactured by various concerns.

Simple drugs and chemicals such as senna leaves, chamomile flowers, sulphur, Epsom salt, etc., should be kept ready in packages for immediate distribution upon call. The old time paper package frequently made up while the customer waited, by scooping some of the material out of a drawer and weighing on the scale in the front of the counter, is a thing of the past. People have been told so often that packaged products are more sanitary than the same substance bought loose, and most of our food products are supplied in that fashion, that they are no longer content with receiving paper packages of drugs. It is of course required of a good clerk that he be able to fold a neat paper package and the public appreciates the neatness of the package but, for the convenience of the customer, packages of drugs and chemicals should be sold in paper cartons, tin boxes, or bottles. Such boxes fit into the medicine closet in the home and continually keep the name of the distributor before the person using them. In some sections people are given to much self-medication and the package trade in drugs and chemicals is large. It can be made a very profitable trade if rightly handled and if a careful selection has been made of standard products even though these cost a little more. Crude vegetable drugs should be kept in metal containers to prevent the ravages of insects and rodents. The packaging of simple drugs and chemicals can be carried on during the spare time of the various members of the store force or the drugs and chemicals can be purchased from wholesale or manufacturing houses in packages all ready for sale. These products may be kept in drawers or in a wall case behind the wrapping counter. It does no harm to keep them near the rear of the store as this causes the customer to follow the clerk to the wrapping counter where he has an opportunity to talk to the customer while reaching for the item and wrapping it, and it also brings the customer within view of other merchandise which he may purchase but would not have thought of, had it not been called to his attention.

The handling of proprietary articles or so-called "patent medicines" takes a considerable share of the pharmacist's time but frequently does not yield him a fair profit because many of these remedies are sold at cut prices. It has been conservatively estimated that there are in the neighborhood of 30,000 different patent medicines on the market. Many of these have only a local sale but others are distributed over the entire country and because of national advertising are in great demand. Every druggist has to carry a fairly complete line of these products to satisfy the particular demand of his neighborhood. With the exception of the so-called "agency lines" of proprietary products in which the druggist usually has a special interest, the tendency is not to give patent medicines very much display room. It is assumed that they will be asked for when wanted and therefore do not require display and, in fact, much display is not desired for them by the druggist because he does not profit greatly by their sale. It is a matter of economy however to keep these medicines where they can be wrapped quickly and the usual place is behind the wrapping counter at the rear of the store. Surplus stock may be carried in cupboards or closets in the prescription or storeroom or in the top of display cases at the rear of the store. Small package patent medicines such as headache tablets, corn cures, laxative tablets, etc., should be carried in drawers with adjustable and removable partitions so spaced as to divide the stock in each drawer.

The agency lines such as Rexall, Nyal, Penslar, SanTox and others occupy a different position with the pharmacist because they are usually sold at the full price and the agencies are given only to certain stores, thus making the line exclusive for any given territory. When these products are advertised to the public the pharmacist holding the agency profits directly from the sale of goods in the line and also because of the decrease in the unprofitable business in other patent medicines used for the same purpose. There is no labor connected with handling patent medicines excepting the ordering, unpacking, and placing them on the shelves ready to be handed out. The fact that the pharmacist as a rule has no special interest in the sale of proprietary medicines should not keep him from giving good service in the distribution of these products, as the public judges service not by the manner in which the retailer sells an item in which he is interested but by the manner which he assumes in his dealings as a whole. The maintenance of fresh stocks, keeping the packages properly enclosed or otherwise keeping them free from dust, are just as essential here as in any other class of merchandise.

It is now common practice for pharmacists to paste a price sticker on every package of patent medicine—such stickers bear the name of the pharmacist and have space for inserting the selling price. While excellent protection is afforded by the food and drug laws of Federal and State Governments against fake remedies, new products are constantly being put on the market and sometimes their manufacturers are not as scrupulous as they might be. It is therefore advisable to carefully watch the claims and methods of marketing followed by introducers of new remedies. If the claims are palpably false the pharmacist should not lend his name to their advertising or sale. Any proposition to advertise the pharmacist in connection with a patent medicine should be looked at from the ethical standpoint before it is viewed from the standpoint of financial returns and permission to use the pharmacist's name should be refused unless it can be demonstrated that the product is a worthy one.

In opening and stocking a new store where the demand for certain proprietary products is entirely unknown, the wisest procedure is to order only from one-twelth to one-fourth of a dozen of each commonly sold patent medicine as a great deal of money can be tied up in dead stock of this kind if not purchased conservatively. The lure of special discounts and free goods should be resisted until definite information is at hand as to the sales possibilities of any article. So often it happens that a proprietary product which has a large sale in one section of the city is only rarely called for in another section.

Patent medicines are the favorite mediums for price cutting on the part of chain store organizations and other down-town stores. They are singled out because they are extensively advertised and the price is printed on the package, as a rule. When a reduction of some magnitude is made the glib-tongued salesman can show the customer how much cheaper he sells his goods by a comparison of the printed price and the actual price charged. This system of cut prices has undoubtedly added to the disrepute in which some patent medicines are held by pharmacists and efforts are being made by manufacturers to prevent price cutting because they realize that when a pharmacist is compelled to sell any item at cost, or a little above cost, it is natural for him to recommend something else on which he makes a decent profit.

Hospital Supplies

Comparatively few pharmacists realize what great possibilities there are in building up a business on hospital supplies which include such things as absorbent cotton, gauze, various antiseptic and sterilizing agents, catgut, surgical

instruments, sick-room appliances and similar necessities. As a rule a minimum number of items under this class are carried in stock for emergency purposes but it is a fact that the stores which become known as headquarters for supplies of this type are usually the ones that are sought out in case of necessity. Very often several other neighboring stores are passed in order to get to the one which is known to have the articles wanted in stock.

This is a distinct type of service which every pharmacist should be prepared to render. It is not necessary to tie up much capital in stock of this character if a real effort is made to acquaint the neighborhood and particularly the medical profession with the fact that it is available. Many pharmacists bid on the supplies ordered by hospitals in their communities and virtually act as buyers of these items for the hospital authorities. A reasonable profit can be made in this field as well as in any other.

Rubber Goods—Atomizers, rubber gloves, hot water bottles, syringes of various kinds, nipples, rubber tubing, bed sheeting, rubber bandages, oiled silk, finger cots, etc., constitute a part of the stock of the rubber goods department and very often the business in this line is large enough to warrant someone devoting considerable time to it. Rubber goods are among the most profitable items sold in the drug store. Proper display in a suitable case and an occasional window display no doubt help sales of these items. In recent years it has been possible to obtain a manufacturer's guarantee for practically all articles coming in this class, and the methods of manufacture have been so improved that flaws in the goods are very rare. They can therefore be sold with confidence and with a "money back" guarantee or an exchange guarantee which inspires confidence. The location of this department is usually toward the rear of the store where people have an opportunity of examining the goods privately and without haste. There are stores in certain neighborhoods where hospital supplies are added to this line and where trusses, crutches, and similar items are also handled. If the pharmacist goes into the business of selling trusses, a separate room is, of course, necessary. Whoever has charge of this department should be well acquainted with the uses of the various articles sold, should be qualified to do some fitting of trusses, and should give proper instruction as to the best methods of preserving the rubber and also what is most economical for the customer to buy. The selling of trusses in a pharmacy is much more frequent in a location some distance from the larger cities, for in the latter special dealers are usually found, well equipped to permit an assortment of the various supplies in this line and with trained attendants for taking measurements and making fittings. If a pharmacist finds an opportunity for such business in his community it will be to his advantage to become the agent for one of the well-established firms, which already has gained the confidence of physicians, and learn from them all about assortments and even the proper methods for fitting, measuring for, and handling this line of surgical goods.

Tobacco Products

Cigars, cigarettes, and other forms of tobacco have come to be a part of the regular stock of the average pharmacy. There was a time when the so-called drug store cigar came in for considerable criticism and was made the butt of many a vaudeville joke. However, modern methods of keeping cigars and handling them have lifted this prejudice and have in fact made the drug store a more desirable place from which to purchase tobacco goods than many of the old time cigar stores.

The smoker wants his tobacco neither too dry nor too moist and he appreciates quick service and the ability to obtain his particular brand of tobacco. Comparatively few drug stores display or handle chewing tobacco because as a rule they do not care to cater to the class of trade that purchases it. A small stock is frequently carried for the convenience of other tobacco customers but no particular drive is made for this kind of business.

The cigar, cigarette, and tobacco trade often leads to trade in pipes, pouches, humidors, fancy cases and holders for cigars and cigarettes, cigar cutters, tobacco jars, etc.

There is no more particular trade than the cigar trade. A man will often walk several blocks out of his way to get the particular cigar he wants. A study of the tastes of customers will be an asset to the pharmacist who wants to make the tobacco trade profitable. He can have a special brand of cigar made up under his label or become the exclusive agent for certain brands which will help to build a reputation for him. Proper fixtures are of considerable help in this connection. A good display of cigars, with proper atmospheric conditions maintained, cannot help but please the eye and the taste of the customer. Cigars should be kept at a humidity of 68 degrees and at a temperature of about 65° F. Slight variations are of course immaterial. Thermometers and hygrometers are not expensive and should be kept in the cigar case and used. Tobacco should not be permitted to become dry, for even though it is remoistened it will not have the original flavor. There are various types of moistening devices. Most of them depend upon some absorbent medium which takes up a quantity of water and gradually loses this by evaporation, keeping the case moist in the meantime. Electric moisteners have been placed on the market but on the whole have not met with great success. The amount of moisture in a case may be increased by warming the water placed in the case with electric lamps. Lining of cases has been suggested as a method of maintaining proper humidity but it is a question whether this has any effect as the opening and closing of doors and reaching into cases after stock causes many changes in the air in the case during the day. The only way proper conditions of moisture can be insured is by carefully watching the case and supplying additional moisture whenever necessary.

Cigarettes are an important feature of the tobacco department and are sold in very large quantities. They may be displayed in wall cases or in top display cases placed on the regular show cases. These move so rapidly as a rule that the foil in which they are wrapped acts as a sufficient protection to make them reach the customer in good shape. The same is true of packaged tobacco.

A separate mailing list of cigar customers is desirable so as to keep them informed concerning the addition of new brands and to advise them of special sales or quantity offers. It is quite possible to cultivate and encourage a box trade in the cigar business and this adds considerably to the profits of the department. Where the tobacco trade is sufficiently large it pays to have an expert in charge of this part of the business. A periodical devoted to the tobacco trade should be among the journals subscribed for by those interested in building up this department of the business.

Effective display at the tobacco department is very profitable to the store. For instance, men are said to buy 76 per cent of the box candy. In addition to this they buy shaving supplies and hair tonics. If these are all kept within easy reach of the tobacco department, very many more profitable sales will result at that department. The small margin derived from tobacco and cigarette sales may be counteracted somewhat by the larger margin on men's toilet goods. Men, as a rule do not go shopping to see what they can see.

They make their purchases where it is most convenient and consequently the items that interest men must be placed where they are accustomed to buying.

Confectionery—The amount of candy sold in the United States during a year is enormous and a large part of it is sold in drug stores. The sales of confectionery in stores which handle it amount to about 5 per cent of the total volume of business. Under the general heading of confectionery there is included both box and bulk candy, fruit tablets, cough lozenges, cake chocolate, chewing gum, and other items. The gross margin on confectionery approximates the standard figure of 33⅓ per cent on the selling price and the rapid turnover of this business makes it a very profitable asset, provided the store is so located as to be able to cater to the candy consuming public. Much of the business on candy is attracted by proper display and inasmuch as this is a line which deteriorates and under certain conditions becomes unsalable, it is important for the pharmacist to give some attention to proper methods of preservation as well as display in handling confectionery. There are some stores in which a penny business is developed and where bulk candy is sold to a much larger extent than package candy. The package trade is to be preferred because it does not require the great care necessitated by bulk candy to keep the display from looking mussy and unattractive and it also does away with the pilfering of the stock which is often indulged in both by clerks and customers. Package goods are usually so attractive that they will enhance a display although the actual sight of tempting chocolates or bon bons will be a greater inducement to the purchaser than a pretty box. For this reason an opened package, particularly one which is very attractive, is an asset to any display. Bulk business very often leads to a good package business also, and it has an advertising value from that standpoint.

The possibility of developing a candy business depends somewhat on the character of the competition in this line. For example, if there is a high grade confectionery store within a short distance of the pharmacy a considerable part of the candy business will naturally go to that establishment. In such cases it pays the pharmacist to take on a line of superior package candies for which he may be able to obtain an exclusive agency, thus drawing a trade to his store which will not be tempted away by the confectionery establishment as long as the package line is well advertised, reasonable in price, and of a sufficiently good quality to be sought out by customers.

Where the stores are equipped with soda dispensing tables it is possible to display candy either under the glass top of the table or in the wall cases in front of which the tables are placed. It is unwise and unsanitary to display bulk candy in such a way that it may be handled by customers or exposed to dust and flies. Slant front show cases are better for the display of candy than straight front cases. In making window displays of candies it is important to shield the window from the sun so as to avoid discoloring chocolates or causing other pieces to collapse. Usually a candy window is provided with dummy packages furnished by the manufacturers thus giving the effect of the display without subjecting any of the stock to deterioration. In some localities, as for example, at the seashore and in very warm climates, it is extremely difficult to keep chocolates in good condition during the summer. Many pharmacists discontinue handling certain candies during this season, especially in bulk, or they specialize on confectionery put up in metal containers which are more apt to preserve the candy than the ordinary porous pasteboard or paper box. Some pharmacists have installed refrigerator display cases which are kept cool either by means of an electrical device or by the presence of ice in the upper or lower portion of the case. However, it has not been found very practical to properly

refrigerate an ordinary large show case, such as is usually used for the display of candy. High temperatures soften chocolates and when the temperature drops, the cocoa butter in the chocolate solidifies and causes a discoloration. The melting point of cocoa butter is around 91° F. but the ideal temperature for keeping chocolates is considerably below that. Some candy manufacturers claim that their products will keep at as high a temperature as 85° F. without discoloration, provided there is no sudden chilling. The ideal temperature for preserving chocolates is in the neighborhood of 70° F.

Refrigeration of candy is sometimes objected to for the reason that the rapid change of a package of candy from the low temperature of a refrigerator to the high summer heat of the atmosphere causes the chocolate to turn gray. The dampness of a refrigerator may also cause molding of the candy.

Reserve stocks of candies may be kept in a cool basement or other storeroom during very warm weather and the display during that period can be made up of dummy packages.

The turnover of candy stock is usually very satisfactory. In most stores it averages from six to nine times a year as compared with the average total stock turnover of approximately three.

It is advisable to place the candy case somewhere near the soda fountain or the cigar case as soda fountain and cigar customers are frequently also candy customers or can be made candy customers by placing before them an attractive display. The man buying cigars for himself is apt to think of candy for the ladies if he sees a display of confectionery. The fountain customer has his mind on sweets and is in a receptive mood to purchase candy if it is close at hand. At one time, drug store candy was not considered of as high a quality as candy purchased in a confectionery store. This was in all probability due to the fact that candy bought in a drug store acquired the odor and taste of drugs. Sugar, and confectionery in general, absorbs odors and if the drug store is charged with odors of pungent drugs and the candy is not properly protected against such absorption, it is certain to have a "druggy" taste. However, the modern candy case prevents this absorption of odors, if it is kept closed when sales are not being made. The newer methods of packing candy and covering the containers with impervious paper prevents the absorption of odors to a large extent and candy purchased from drug stores no longer has the objection that was once offered. As a matter of fact the drug store has become an acknowledged source of high grade candies because so many pharmacies have received exclusive agencies in their territory for some of the best lines.

Special days, such as St. Valentine's Day, Mother's Day, Hallowe'en, Washington's Birthday, Easter, and Christmas can be taken advantage of for the purpose of selling candy and special sales of a particular package for the particular day will add much profit to this department.

Stationery and School Supplies—The department devoted to stationery and school supplies can be made a very large one if the store happens to be so located as to attract a great many school children or high school and college students. If there is a school of any kind close by, the pharmacist has an extraordinary opportunity in this direction. Where there is no school in the immediate neighborhood the stationery business will be largely along the line of writing paper, correspondence cards, special cards at various seasons of the year, such as Easter, Christmas and New Year cards, and various accessories, such as fountain pens, pencils of the automatic type, sealing wax, and so on.

If a pharmacist happens to be the only one, in a small town where there is no progressive stationery store, he can make his establishment headquarters for information regarding the correct use of correspondence cards, invitations

to various functions, etc. He can obtain the agency for an engraving house which will supply him with samples of various styles of engraving, and an excellent business can be built up in supplying visiting cards, wedding invitations and announcements, and similar items. Here again the importance of display cannot be over-emphasized. Showing the various styles of cards and engraving and indicating that they are the styles advocated by high-priced houses in large cities, also being acquainted with the correct form and procedure for each social occasion and ready to give help when asked for, should make it possible for the pharmacist to build up this business. In the larger cities there is not so much opportunity for it, unless the store is located in a neighborhood where the people do not have the opportunity to shop in the down-town districts. The stationery and school supply line should be very profitable because it is clean, requires comparatively little attention, and turns over rather rapidly. It is not advisable to show the styles of cards, letter paper, envelopes, etc., from stock packages. It is much better to arrange a set of sample sheets of paper and envelopes of different colors and qualities, neatly on a paper or in a folder which can be shown for style, thus keeping the stock in the packages clean, neat and free from finger prints.

Soda Fountain—It seems almost impossible to think of a pharmacy without a soda fountain. As a matter of fact, in a recent investigation of what drug stores sell, out of 1000 stores picked at random only 678 operated soda fountains. When it is borne in mind that 956 out of 1000 in this investigation sold candies, 948 sold cigars and tobacco, and 996 sold stationery, the soda fountain in the drug store is not as universal as seems to be generally supposed. The question has often been asked how the drug store came to sell soda water, and, undoubtedly, this was an outgrowth of the fact that the original carbonated water was made from CO_2 gas, generated by the interaction between marble dust or, later, sodium bicarbonate and sulphuric acid, which involved a mixing process that the ordinary storekeeper would not undertake. It has not been many years since the old-style soda fountain, with its apparatus for generating carbon dioxide with which to charge the water, was a drug store fixture. The desire to improve the taste of the carbonated water led to the use of fruit syrups with the charged water and this in turn led to the introduction of the ice cream soda which it is said was developed during the Centennial Exposition in Philadelphia in 1876. Soft drinks and soda water have been popular for many years, but of course the sale of these non-intoxicating products has increased very largely since prohibition laws have been in effect. Improvements have been brought about in the building and equipment of soda fountains so as to make them more efficient, more durable and more easily operated, and the soda business has in many cases been extended to include light lunches, such as hot drinks, bouillon, sandwiches, cake, pies, etc. Once the public begins to demand articles in the food line it is difficult to know where to stop in meeting the demand. A soda fountain located in an accessible place for people who want light lunches is almost compelled to add other articles of food in order to maintain its business.

Where the soda business is large enough, it is of course profitable to conduct it as a separate department of the store with someone in charge who is held responsible for profits and losses. There is no harm in having a soda fountain under the same roof with a prescription department if both are conducted according to ethical principles of business.

Various factors enter into the location of the soda fountain in the store. Those located in a transient section near railway stations, amusement parks, or at summer resorts, would be served best by having the soda fountain at

the front of the store or very close to the front where it can readily be seen by the passing crowds. An attractive fountain will show off to better advantage at the front where the light is good, than elsewhere. Of course, if the fountain is located at the front of the store, which is considered the most valuable space, it must pay a proportionate share of the rental and the soda business must warrant this extra expenditure.

When the fountain is located toward the center of the store it can be used to draw trade to other departments by compelling fountain customers to pass the candy case, cigar case or toilet article counter. Where a quick lunch is served in addition to the usual fountain drinks, it is sometimes preferable not to have the fountain located right at the front where people can be seen through the store windows by passersby. Furthermore, a more central location does not interfere with merchandising at the front of the store and does not crowd the entrance at certain times and repel customers for other departments.

Soda fountains are not very often located in the rear of the store but in neighborhood sections where there is not a large fountain business, it may be advisable to locate the fountain at the rear, because it adds privacy and in case there is a side entrance it makes it easy for fountain customers to come and go without interfering with other departments while adding to the tendency of neighborhood customers to make the pharmacy a meeting place for discussing the news of the day, etc., at their leisure while sipping a soda or eating a plate of ice cream. The soda fountain should not be used to encourage loafing around the store but in certain districts it is to the interest of the pharmacist to cultivate the desire of neighbors for a place to meet occasionally, and if handled judiciously, the fountain, under such circumstances can be made a splendid asset. If a customer is required to walk the full length of the store to reach the fountain, there is, of course, greater opportunity for additional sales.

In most stores the fountain is located at the side with wall space acting as an accessory for display and storage and usually for a mirror which adds to the beauty of the fixtures. In large stores the fountain is sometimes located in the center either in the form of a hollow square or in the shape of an L. It is inadvisable to install this style of fountain excepting where there is plenty of room, so that no other department will be crowded as a result of the installation. Inasmuch as every portion of this type of fountain is in plain view of customers everywhere in the store, it requires additional labor to keep it spotlessly clean and in order, so as to avoid the general appearance of disorder which would result if it were not properly cared for. Fountains located in the center of the store detract to some extent from the wall case displays.

Very often separate rooms or porches adjacent to large stores at vacation resorts and elsewhere are used for fountain service. In such cases it is necessary of course, to have someone to give attention to the tables but there is an advantage in having soda customers segregated, especially if the business is very large. The disadvantage here is that people do not see the rest of the store while enjoying a soda. Some form of entertainment in the way of a victrola or radio outfit may add to the enjoyment of a special department of this kind.

In purchasing a soda fountain, preference should be given to the apparatus which is most easily kept clean and least apt to get out of order, other things being equal. If the store is a new one, it is possible to make the fixtures harmonize with the fountain or vice versa. If the store is already equipped with fixtures and a new fountain is purchased this should harmonize with the furniture as much as possible. Ordinary tables can be used in some localities whereas in the better neighborhoods and in transient sections the table with a

display top is given preference. Too much ornamentation is not advisable as it gives rather an unfavorable impression and adds to the labor of cleaning. Simple designs which are easy to keep clean are best in the long run.

The space back of a soda fountain can be used to display confectionery and other attractive articles and a mirror and some colored glass are usually a part of the equipment for ornamentation. If possible, there should be easy access to the basement where the soda fountain and the surplus stock of ice cream, etc., are kept. If a dumb waiter can be arranged it is found to be of considerable help.

The soda fountain should act as a magnet to draw people to the store and it therefore has a twofold purpose. It is not only a profit producer itself but is an advertising medium in that it brings people into the store where they may see other things or remember other items,in other departments, which they buy. In a busy section it is customary to provide for standing room at the fountain and tables for those who wish a more leisurely service. In other localities the front of the fountain is provided with seats. This will usually attract more women customers than would otherwise be the case. Men are more apt to want quick service and prefer to stand. The matter of seating is an individual problem with each store and must be worked out according to the particular requirements.

The soda fountain equipment should be adequate for the volume of business that must be transacted in a certain location and it should be of a type that will always give a neat and clean appearance. Nothing will destroy a soda business or a business in any food product more quickly than a disorderly and dirty service counter or the presence of clerks who are not neat and clean. Much soda business is also destroyed by the odor prevailing about many fountains. There is no excuse for a condition of this kind as proper cleaning of the ice cream cabinets and the apparatus in general will prevent disagreeable odors. There should be hot running water available for cleaning purposes. To do away with the trouble of cleaning glassware, paper cups and dishes have been adopted very largely in busy stores, although some of the largest stores continue to use thin glasses which they claim are preferred by most customers. Such stores, however, provide adequate facilities elsewhere for cleaning the glasses and dishes which are returned to the fountain clean and dry.

In the management of the soda fountain in a number of stores the cost of supplies is carefully maintained within 50 per cent of the sales.

This figure is readily checked each week and is of great value in maintaining a profitable business. If costs exceed this per cent it is an indication of unnecessary waste or perhaps an undue quantity of syrups, cream, or ice cream is being served or perhaps the clerks are partaking too freely of the service at the expense of the proprietor.

The type of fountain to be selected cannot be decided upon without giving considerable study to those available at the price which the pharmacist is warranted in spending. A great deal of money can be tied up in a soda fountain which will never be justified by the business that can be done in a particular locality. To prevent such mistakes it is wise to consult soda fountain experts, more than one if possible, and carefully survey the local conditions before buying.

If the soda business is being run as a profit producer, plans should be made to keep it going all the year. There are many cold drinks demanded in the winter time and the sale of ice cream in one form or another is not stopped by the coming of cold weather, furthermore, it is possible to add a few hot drinks,

such as chocolate, coffee, tea, and perhaps bouillon, which will appeal to quite a number of people at various times of the day. Of course, if it is found to be unprofitable to handle hot drinks in the winter and the cost of keeping the apparatus going and supplying the necessary materials is excessive it is unwise to continue this development, although the question of service and convenience should be taken into consideration before discarding any feature which a portion of the customers of the store have become accustomed to and which therefore has a certain advertising value.

The life of a soda fountain is not dependent so much upon the possibility of wearing out but rather upon how soon it may become out of date. The average soda fountain becomes obsolete within five years, and to use the older type of fountain after that period very often makes it a liability. Depreciation on the soda fountain should therefore be charged up at the rate of twenty per cent a year.

Toilet Articles, Perfumes, etc.—The business on toilet articles, cosmetics, etc., has grown to enormous proportions in recent years and many pharmacists have taken advantage of the opportunities for additional profit and service offered along this line. Few, if any, retail pharmacists manufacture more than one or two specialties in the line of toilet articles and while some have such products manufactured for them and labeled with their name, the greater portion of this business is on advertised goods. Lip sticks, compacts, powders, and the various accessories and varieties of these are in great demand and the favorite brands vary with the neighborhood and with the section of the country in which the store is located. Much of this business is controlled by the national advertising of the manufacturers in popular magazines, newspapers and other mediums. Of necessity the pharmacist should have on hand the most popular brands and, where the quality is equal, it is to his interest to push those brands which yield the greatest profit. Experience indicates that it is not advisable to spend very much time in overcoming the prejudices which customers for these items have already formed so that the degree of sales resistance to any particular item is also a factor to be considered in stocking it. Even though the profit may be large, if the sales resistance is great, it is better to be satisfied with a smaller profit and have satisfied customers. The packages in which toilet articles are put up are usually quite attractive and if well displayed they are bound to produce business without very great effort on the part of the pharmacist. There is keen competition in toilet articles with department stores, and unfortunately the profit in some of the leading items is lowest because of cut prices and the necessity of meeting competition. In the same department where face powders, face creams, massage creams, hand lotions, powder puffs, vanity cases, etc., are displayed it may pay to add such items as complexion brushes, nail buffers, orangewood sticks, manicure scissors and knives, nail files, cuticle remover, tooth paste, tooth powder, antiseptic solutions used as mouth washes, perfume atomizers, etc.

The sales of perfumes and toilet waters although taken over largely by the department stores in some localities still constitute quite an item in the average drug store. Proper display and the right atmosphere, in the particular section of the store where these items are stocked, play a large part in the possibility of building up this business.

Miscellaneous Items—As has been pointed out previously, the location of the pharmacy and the fact that it is open sometimes as long as eighteen hours out of the twenty-four, and frequently does not close at all, makes it a convenient point of distribution for all kinds of merchandise, so that the

pharmacist of to-day finds it very difficult to know what to handle and what not to handle. He is offered agencies for all kinds of articles, many of which are entirely foreign to the objects of conducting a retail drug store. As an example of the extremes to which the matter of using the drug store as a distributing center is carried, we might cite the fact that a pharmacy in a large hotel in New York City is reported to carry shirts and pajamas for the convenience of travelers in emergencies. Among the items which are carried to some extent in various pharmacies are bathing caps and shoes, books, paints, wall paper, cameras and photographic supplies, jewelry, glassware, cutlery, leather goods, pictures, ivory and celluloid goods, magazines, musical supplies, souvenirs and novelties, optical goods, razors, sport goods, and vacuum bottles.

It has long been customary for the pharmacy to be headquarters for brushes of various kinds including tooth brushes, hand brushes, hairbrushes, hand scrubs, bath brushes, etc., sponges, chamois, and various other items that are usually classified as sundries. These articles yield a good profit and when reliable lines are handled it is possible to build up a satisfactory trade in them.

The Inventory

Value of Inventory—It is impossible to determine correct annual profits, to make out income tax returns correctly or to file accurate corporation tax reports without taking an annual inventory of the stock of a pharmacy. There are no short-cuts if the record is to be accurate. Furthermore, the taking of an inventory, if properly prepared for and carried out systematically, is not impossible or even a terrible bugbear, as believed to be by most retail druggists. Of course if one attempts to write down the items from one end of the store to the other, then price them and afterwards extend the totals, all at the same time, and keep the store open and wait on customers, there is every reason to give it up in disgust. But when the taking of an inventory is accepted as a requirement and conducted systematically, it can be accomplished in a comparatively short time. The value of an inventory lies not alone in the revelation of what the store is worth and how many times the stock has turned in the year but it gives much more information. The proprietor has an opportunity to know the stock. It often shows what to avoid this year that caused difficulty last year. If he wants to sell, he will know what his stock is worth and what the store should bring. Should there be a fire, the inventory will give an honest basis for adjustment. It is always well to have the inventory in duplicate, one copy being preserved in a vault outside the store so as to be intact in case of fire, theft or other loss.

Most proprietors like to have their business year run parallel to the calendar year. This brings inventory time around the last week of December which is usually a busy period and a very inconvenient time for taking inventory. There is nothing compulsory about the date. The business year can just as well be adjusted to end in the summer or at some other slack season when there would be more time for inventorying. But no matter when it is taken, it should be taken at least once a year.

Methods of Taking Inventory—Very often the annual inventory results in the discovery of unsold stocks of merchandise which should be gotten rid of quickly in order to release capital or take advantage of price situations. The taking of an inventory is greatly facilitated if the stock is systematically arranged. In large organizations it is an easier job as each department is usually in charge of an individual who is thoroughly familiar with all articles on sale and who has them well classified.

The Liggett stores use their inventory as a means of control upon a number of business factors. Consequently, their inventory must be frequently taken and must represent accurate facts. To facilitate this, the stock of every store is printed upon sheets in the order in which the item appears upon the shelf, and separate lists are made up for each department. This greatly facilitates the taking of the inventory since the items can be called off in the order in which they rest upon the shelves and the quantity entered upon the sheet with the sales price, which is supposed to be written upon every package.

Notice that in this organization the inventory is taken at the *selling price,* although it is usually the custom to price items at cost. The inventories just referred to are taken at least twice a year, at irregular intervals, by a so-called "inventory team", consisting of a captain and six men. The largest Liggett store can be inventoried completely by this team within a few hours, without interfering with the regular business. Taking an inventory in this way is, of

course, only possible when a large organization and a number of stores are involved.

In a smaller store, or group of stores in which there is a division of the business into departments, an inventory may be rather easily taken by distributing ruled sheets to those in charge of the various departments, several days before the inventory is to be taken. These individuals write up the items in their departments in the order in which they are placed upon the shelf. When the inventory day comes, one person can call off the quantities and the second write them on the sheet, thus completing the task in each department in the course of several hours. The sheets are then collected, the cost inserted by the buying department, and the totals determined by the bookkeeper. This method is applicable to almost any business and is one of the most efficient plans.

Several organizations in the drug trade have offered special printed forms which are useful in making up an inventory. The National Association of Retail Druggists offer a small pamphlet in which many of the common items are printed, with space for entering quantities for several years in succession (see Fig. 465). The American Druggists' Fire Insurance Company presents its customers with inventory sheets upon which the individual items may be written and with space provided for quantity entries for ten years (see Fig. 466). Either of these would be of help when taking an inventory. If the

proprietor has little or no help and an actual physical inventory has been taken at some date within a reasonable time and the relationship between the cost of goods and sales for the preceding year has been determined accurately, it is possible to calculate approximately the present value of the stock by adding to the inventory the cost of goods bought since the inventory was

FIG. 466

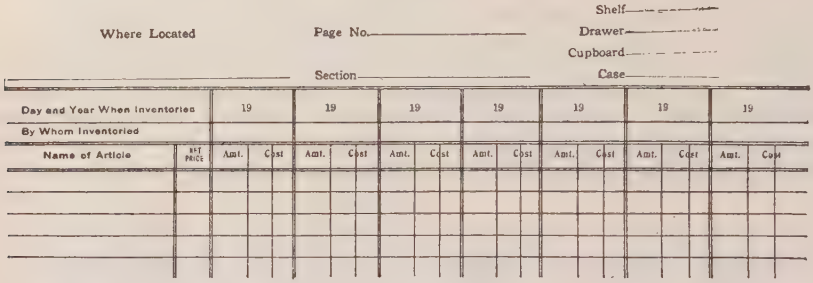

Illustration of the inventory sheets of the American Druggists' Fire Insurance Company (one-half size)

taken, and subtracting from it the estimated cost of goods sold since the actual inventory.

The following will illustrate the calculation:

If the per cent relation last year was:		
Sales	100 per cent	
First cost of goods	65 per cent	
Expenses	25 per cent	
Net profit	10 per cent	
And if the last actual inventory was		$7,000.00
And goods bought since the last actual inventory had cost		$3,000.00
The total value to account for would be		$10,000.00
Now the sales since the last actual inventory were	$4,600.00	
And as the goods sold cost 65 per cent of $4,600.00 or		$2,990.00
Therefore, the present inventory, by calculation (using the law of averages), would be		$7,010.00

This method is not recommended, but in case of necessity will give a fair idea of the value of stock on hand.

There are many items in the stock of the average pharmacy that justify the complaint that taking an inventory in a drug store presents unusual problems, but most of the difficulty lies in trying to take a correct account of open packages and partially filled containers. The inventory should be as exact as possible but there are occasions when only an estimate of the contents of a bottle of tablets or pills, or of some chemical, is justified. The experienced eye can quickly note whether the container is half full or one-quarter full, etc. If a stock container is used for the storing of chemicals and powdered drugs, an empty container of the same type, placed as a tare on one side of the scale, with the partially filled container of the substance to be inventoried on the other, the approximate weight of the contents can be readily determined with sufficient accuracy for the purposes of the inventory. In the case of

liquids a measuring stick is sometimes employed. This can be prepared for standard quart, pint, and half pint bottles by taking an empty bottle, adding an ounce of water, inserting the dry stick until it rests at the bottom of the bottle, taking it out and making a mark at the top of the moistened section, and continuing the process, ounce by ounce, until the measuring stick for that

Table for determining the cost of fractions of a dozen

particular bottle has been completed. At inventory time, it is only necessary to place the stick along the side of the bottle and determine quickly how many ounces of liquid it contains. Of course, there must be a different stick for each type of bottle. If the bottle is uniform in width it is not necessary to prepare the stick by dipping it into a bottle to which an ounce of water at a time is added. One can simply determine the length of stick required to measure an ounce and then divide the stick into sections according to that measurement.

For example, if an ounce of liquid in the bottle measures half an inch, the stick can be divided into half inch sections, each representing an ounce.

In the case of pills and tablets where a bottle is known to hold 100 tablets when nearly filled the remaining number can be estimated by the amount of space in the bottle. The same is true in the case of powders, although, of course the specific gravity of the powders must be taken into consideration and where the quantity is fairly large it is best to weigh it, using an empty bottle to balance the container.

When the inventory sheets are prepared in advance and it is only necessary to call off the items and quantities, leaving the pricing to be done later, it is not a very difficult matter to run through the stock of a store in the course of a day. Whether or not to close the store while inventory is being taken is a question that must be determined by each storekeeper. Sometimes a Sunday or a holiday is used, or the store is closed on a day when it would not be very busy anyway, giving notice to the public that prescription and emergency service are being continued but that the other departments are temporarily closed. It is also possible to avoid closing the store by taking the inventory at night and using sufficient help to cover the store in a given time. The store force can be divided into teams, one man calling off and the other writing down, with one team starting at one section, another at a different section, and a third at still another location. In this way the work can be expedited. In the larger stores this is carried out very quickly.

While alphabetical lists of the items in the drug store stock are valuable, especially when it comes to pricing—the price lists being arranged alphabetically—for purposes of rapid inventorying the lists arranged according to the location of the various articles in the store are preferable.

In some large establishments arrangements are made for weekly or monthly inventories of individual departments. What amounts to a perpetual inventory can very readily be arranged in bulk stockrooms if one has the personnel and the facilities to carry it out. In such a case the stock in the storeroom is listed on a card fastened to each bin or section. Whenever anything is removed the quantity is subtracted and when anything is added this is likewise noted. The card therefore shows not only the contents of the bin but the actual quantity of each item which should be there. The amount of stock on hand can thus be noted at any time.

A table of extensions (see Fig. 467) is useful in rapidly calculating the cost of fractions of a dozen.

CHAPTER LXXXIII

METHODS OF EXCHANGING COMMODITIES OR SERVICE FOR PROFIT

The methods of exchanging service or commodities for profit in any profession or business involve advertising and selling. Both advertising and selling are subjects of special and extensive study on the part of those interested in merchandising and it is only possible in these pages to call attention to some of the applications of these arts to the commodities and service offered in the retail pharmacy. For extensive information on advertising and selling problems the student is referred to the bibliography of the subjects given at the end of this chapter.

Advertising

Under the heading of advertising may be considered any fair means employed for the purpose of convincing people of the value of a point of view, a service or a commodity, and in the case of the latter two, endeavoring to arouse the desire for utilization or possession. When advertising takes the form of a word of mouth or printed word message in behalf of a cause—political, social, or economic—it is generally referred to as propaganda. During the World War the word propaganda achieved a more or less sinister meaning which it has not entirely lost. It was used to designate in an uncomplimentary way the efforts of foreign powers to present their cause to citizens of this country by means of special publications, lectures and the circulation of stories for newspaper publication in such a way as to malign their enemies and endeavor to secure our support. As a matter of fact, propaganda of one kind or another is essential to the promotion of any just cause. The objection to the term and to propaganda itself has no foundation as long as it does not represent unfair and reprehensible methods or activities.

If physicians through their medical organizations take steps to issue articles to the newspapers condemning the use of proprietary medicines or self-medication in general they consider this proper and legitimate propaganda in the interests of the public health. Manufacturers of proprietary medicines on the other hand look upon such publicity as propaganda directed to the destruction of their business and in favor of bringing patients to the doctor's office. The interpretation depends entirely on the point of view and it can be seen at once that there is no fault to be found with propaganda as such but rather with the point of view which the propaganda attempts to popularize. Propaganda is a form of advertising, usually in the nature of reading matter, which is taken advantage of by all kinds of advertisers and is considered legitimate as long as no attempt is made to spread information which would be seditious or inimical to the welfare of the people.

Every year during the national and local election periods the managers of the various political parties issue reams of propaganda in behalf of their candidates to various publications and much of this matter is served to the public in the form of newspaper and magazine stories. The average citizen does not realize that most of this matter which he reads in his daily paper is prepared in the office or by the direction of the campaign committee and is naturally colored to suit their specific purpose. In the Baltimore Sun of November 23, 1923, there appeared the following statement by Frank R. Kent,

a well-known Washington correspondent which gives an interesting side-light on this subject:

> "Every one of the active presidential candidates today—and some who are apparently though not actually, inactive—has a publicity machine of his own hard at work. McAdoo has one, Underwood has one, LaFollette has one, Hiram Johnson and Henry Ford have theirs, and President Coolidge has his. The public is not supposed to be aware of the existence of these machines and, as a matter of fact, is very largely unaware of them. The insiders of the political game know about them. The Washington newspaper correspondents and a good many managing editors know about them, but it is the custom not to mention them, pretend they do not exist, to keep the covers on the publicity machine. Most of the stuff—interviews, speeches, statements, articles, little human interest stories and the like—that you see in the newspapers and magazines about these candidates these days look like spontaneous news. It is nothing of the sort. On the contrary, the great bulk of them are the canned products of a nationally geared publicity machine, designed solely to promote a presidential candidacy."

Large scientific organizations and in fact all kinds of organizations whether they be religious, technical, educational, or political now maintain publicity bureaus whose sole duty it is to send out, periodically, information regarding their specific work so as to keep the public informed of what is going on in their sphere and endeavor to create a favorable reaction toward that work. Such favorable reactions often lead to philanthropic bequests for education, for scientific research, or for other purposes. This is not considered advertising in the same sense that a billboard announcement or a paid advertisement in a newspaper is considered advertising. It is really free as far as the cost of space is concerned but it is costly nevertheless because the machinery for preparing and issuing such information runs into considerable money.

With so many publicity bureaus constantly issuing material to the newspapers there is very little opportunity for the individual to get into the day's news unless he does some outstanding thing and attracts favorable or unfavorable attention. There are some individuals who maintain their own publicity bureaus. Noted musicians, actors, moving picture stars, pugilists, politicians and others all have their so-called press agents who issue stories, interviews, or news items about them whenever they desire to attract public attention. It has been generally believed that this kind of advertising is more valuable than the paid advertising because the reader does not classify it as advertising in his mind when he sees it and reads it. On the other hand there are now millions of people who are more quickly attracted through paid advertisements than through the reading columns of newspapers and magazines. This is in reality a tribute to advertising because it indicates that in many instances it has outgrown its former position of being considered a necessary evil in newspapers and magazines. In the past it was generally assumed that the advertiser departed considerably from the truth in explaining the great merits of his products. Today not only is there truth in advertising but more and more advertisements have real literary and artistic merit and frequently give extremely interesting and valuable information. A respectable newspaper or magazine will not accept advertisements that are not in accord with the facts.

The old belief in the great value of obtaining advertising through a story or the mention of a name or a product in the reading pages of a newspaper or magazine causes many advertisers to still demand so-called "reading notices" in newspapers, magazines, and other advertising mediums. The better class of publications have discontinued this practice but in small town papers one still finds in the personal columns and elsewhere short statements extolling some remedy or some individual or concern in a manner to give the impression

that it is an editorial comment. Very often such "reading notices" are paid for at a regular rate.

Pharmacists may benefit to some extent by propaganda work in their behalf but it must of necessity be limited very largely to a discussion of the merits of the profession as a whole, the service rendered, the discoveries made and the legislation fostered or opposed. There is nothing of a selling character in such propaganda, but benefit comes to the profession through the increased knowledge and respect which the public may acquire as the result of reading about what is being done by the profession. Individual pharmacists are in a position to reap the benefit of publicity resulting from their own activities in civic or professional lines and it is entirely proper for them to keep the newspapers in their locality advised of various accomplishments. Very often reporters make periodic visits to those who are apt to furnish occasional news.

Paid Advertising—In general there are two types of paid advertising. (The term "paid" is here used to denote the fact that the advertising appears in space which is purchased.) The first type is intended to sell specific products or services and the second to sell ideas about individuals, industries or members of industries. Let it be imagined, for example, that there are no talking machines of any kind on the market and that such a machine has just been invented. The first step on the part of those who are convinced that talking machines have a great future in the American home and who have backed that opinion by putting their money into an organization to manufacture talking machines would be to sell the American people the idea of getting a certain amount of pleasure out of the ownership of such a machine. They would have to demonstrate the fact that a voice could actually be reproduced and that it would be entertaining as well as educational to bring the voices of noted singers, the music of celebrated artists, and the funny stories of well-known comedians into the home whenever desired. This part of the introductory work would be entirely educational and the advertising in this case would be strictly educational in nature. Having completed the campaign of education and by demonstration convinced a sufficient number of people that talking machines are a good thing to have, the problem now turns into one of selling a specific make of talking machine and as a result there are advertisements, extolling the merits of the Victrola, the Sonora, the Pathé machine, and others, each endeavoring to point out in what particulars it is superior to all other talking machines and endeavoring to sell that particular brand.

In the matter of advertising drug store products to the public a similar example could be cited. A campaign of education to convince people that it is proper to clean their teeth or that it is advisable to use antiseptics for cuts, bruises, etc., is purely an educational proposition. On the other hand the advertising of a particular tooth paste, or tooth powder, or liquid dentifrice is a selling proposition. The advertising of a particular antiseptic solution for use in cuts, burns, bruises, etc., is likewise a sales effort.

Institutional Advertising—We have examples of various industries pooling their resources for the purpose of conducting campaigns of education which will benefit the entire industry but which do not attempt to create sales for any particular product. The national campaign conducted by the florists with their well-known slogan "Say It With Flowers", a similar campaign conducted by paint manufacturers with the slogan "Save the Surface and You Save All" and the endeavor to popularize the idea to "Try the Drug Store First" and that "Your Druggist is more than a Merchant", are all examples of this type of educational or institutional advertising. Such advertising does not attempt to sell a single product or brand of products but rather to convince the public of the value

of making a more frequent purchase of flowers, the preservative value of a coat of paint for a house or the fact that the druggist is offering professional service and that he is most apt to have the things usually associated with pharmacy which might otherwise be purchased at department stores or other establishments. Such advertising is usually followed up by the selling type of advertising in the locality where the individual member of the business or profession is located. A local florist, a local painter, or a local druggist can profit by tying up his advertising with this national goodwill advertising if he desires to reap the full benefit of it. The national campaign tells the people that druggists are more than merchants. The wide-awake individual druggist then identifies himself as the one who is talked about in this national campaign.

At this point the question might be asked when should advertising be of the educational type and when should it be designed to sell goods? The answer to this question would be that whenever an entirely new idea or a new thought regarding products or a service are to be communicated to the public, it is necessary to "sell" the idea first. If the central idea about the product already has been popularized and the individual purchaser is not any longer deciding whether he wants the thing or not but rather which brand of the thing is best, then the advertising should be of a selling nature. There are times when both kinds of advertising can be run simultaneously to advantage. In fact, large advertisers sometimes run them in the same advertisement, the one to keep the public informed of new developments or to keep it "sold" on an old idea and the other to stimulate the sales of a particular product one wishes to dispose of.

Factors Involved in Advertising—The actual publication of an advertisement, no matter what form it may take, involves first a marshalling of facts on which the advertisement is to be based, secondly, the preparation of the advertising "copy", third, the reproduction of the "copy" in acceptable form through an advertising medium. Following the appearance of the advertisement there should be a checking up of results as far as that may be possible.

Preparing Copy—The need for information about the idea or product to be advertised before an attempt is made to write anything about it cannot be overemphasized. Many small merchants while realizing the importance of advertising consider the preparation of the advertisement as merely so much space to be filled with words or illustrations but anyone who has made a study of the subject or even one who has had a fairly good general education is immediately able to characterize an advertisement as good, fair or poor, if it is on a subject about which he understands something. It therefore behooves the merchant to make the space, which he buys in some advertising medium, of real value to himself, by attracting the attention of the reader and holding his interest sufficiently to enable him to absorb the idea which he is trying to convey and to act upon the suggestion to purchase. No one can write effective advertising copy without a knowledge of the facts about a product and some knowledge of the likes and dislikes of people as well as the workings of the average mind. There are some people who instinctively possess the ability to write in a manner that appeals to the multitude. Such people are comparatively rare and are not as a rule found among small storekeepers. To the latter the preparation of advertising "copy" is more or less of a burden. In recent years there has come into being a profession of advertising writers whose life work it is to make a study of how to convince the public through the printed word and who have schooled themselves or have been schooled to write accordingly. The average storekeeper if he is asked to write an advertisement about a

product will, as a rule, look up what has been written about some competitor's product and by changing words and sentences and perhaps adding an argument here and there, produce something which has very little originality about it. What he should do and what a real advertisement writer would do would be to sit down and make a note of all of the talking points that he can think of about the product after a study of its composition and uses. He may then consult the literature and advertising of competitors and see what they say about similar products. Finally he will interview customers who have used the product in order to get not only favorable comment but also unfavorable comment, if there is any. It is important to know both the advantages and shortcomings of a product before one starts to write about it. Having made a record of all of this, it is now possible to write a series of arguments in behalf of the product which will counteract as much as possible, the arguments against it and forcefully state whatever may be said in favor of it.

It will be found when all of the facts have been collected in this way that there is more than sufficient material at hand for a great deal of printed advertising. It is not wise to use all of this information in one advertisement. Of course, when one is writing a booklet about a product all the information can be included, but when one is limited to a small space only one or two arguments can be taken at a time and driven home. By having all of the facts at hand, a series of advertisements can be written at one sitting which will be sufficient to last for several months and after that they may be altered to suit new conditions and used again as the stock arguments will of course remain the same. Anyone who follows the national advertising of popular products knows that it is largely repetition of one or two salient points that makes the advertising effective. Occasionally new thoughts may be expressed but there is always a recurrence of the stock arguments which, once having been impressed on the public mind, are recalled again and again by continuous repetition until they become as much a part of everyone's general knowledge as the days of the week.

Naturalness is most desirable in advertisements. The copy should reflect the personality of the proprietor. By imparting his own individuality to advertisements the proprietor achieves the same effects that he does in personal contacts with his customers.

In writing advertisements and circular letters the proprietor is apt to be influenced by the large number of people he is addressing and his style consequently takes the form of an oration. He should not do this. He should remember that, in spite of his large audience his advertisements are read one at a time by individuals. His style should be personal and not oratorical.

The word "copy" has been used in these paragraphs frequently. Its meaning in the parlance of writers and printers is the manuscript that is turned over to a printer to be set into type. What the writer produces is "copy" to the printer. After the "copy" is set in type, the printer "pulls" a "proof", usually on a long sheet of paper. The "proof" is corrected by the author and returned to the printer who makes the corrections in the type and then "makes it up" into pages, or if it is a display advertisement he sees that it is properly inserted in the space contracted for.

With the facts at hand the writing of advertising copy is largely a matter of stating the facts tersely and in good English that may be understood by the average twelve year old child. One need not be an expert writer in order to prepare a fairly good advertisement if these requirements are met. Very often a fact or a story told in the advertiser's own language and in his own way is far more effective than the flowery language employed by an alleged expert

copy writer. We have many examples in the advertising of the day in which the individuality of the advertiser is the outstanding characteristic and its greatest asset. With the advertising copy there should be sent to the printer a layout indicating how the matter is to appear in the space available. Some merchants are artistic and have their own idea about how they would like to have certain matter appear in print. The printer on the other hand may have an entirely different idea and very frequently if no directions are given for a layout, what would ordinarily be a very good piece of copy, is spoiled by poor display and poor arrangement of the type. To guard against this, a pencil layout indicating the ideas of the writer should accompany the advertisement. One need not be an artist to make such a layout. There are printers who set type as directed to fill space. There are others with some imagination and a sense of the artistic. Fortunate indeed is the advertiser who secures the service of the latter. He can often turn poor copy into effective advertising by his expertness in producing a pleasing effect. Printing service of this kind is worth the extra fee that may be charged.

It is, of course, an advantage to the advertiser to know something about size and style of type and art work. Such knowledge can be acquired by home study or courses on the subject. There are some excellent books on these topics. By going through the printer's book of type faces and stock illustrations and also by a study of the advertisements in our national magazines and newspapers many ideas will suggest themselves.

Advertising Agencies

Reference has been made to the fact that there exists a group of professional advertising writers and it is, of course, well known that much of the writing and placing of advertising is now in the hands of advertising agencies. The service which an advertising agency renders to its clients is manifold and when the agency is a large one its activities lead into practically all the avenues of commerce. There are small agencies which are comparable to the one-man drug store in that the proprietor usually takes care of all the departments of the business and then there are larger organizations in which the work has multiplied to such an extent that each department of the business is in charge of some expert.

The business of the advertising agency includes research work connected with the collection of facts on which to base the advertising; space buying, which includes the task of obtaining the best positions in newspapers and magazines for the insertion of the advertising; copy writing, which includes the preparation of the actual advertising copy, the layout and the art work; placing of the advertising, which includes advice on what are the best mediums for the client and how much money should be devoted to each in order to obtain maximum results; checking, or recording the actual appearance of the advertisement in the newspapers and magazines before it is paid for, and tabulating returns. As a rule when an advertiser entrusts his work to an advertising agency, it costs him no more than if he were to place the advertising direct but he receives in addition, the service of the agency in the preparation of his copy. This service can be supplied because the newspapers and magazines allow the advertising agent a commission usually about 15 per cent, on the advertising placed by them. Where the amount spent for space is very much, the commission runs into a respectable figure. On small accounts it does not amount to much and if there is much service to be rendered, the agency charges the client a fee for that service. There are localities where

advertising agents do not receive commissions from newspapers on local advertising and in this case the agency usually adds 15 per cent of the amount spent as a service charge for preparation of copy and placing the advertising.

Unless a merchant or professional man is acquainted with advertising methods and takes a special interest in the subject and has the time to devote to it, it is really more economical to turn the advertising over to a reliable agency and have them take care of it. They will, of course, confer with the advertiser in order to get his ideas but the actual work of preparing and placing the advertising is taken off his hands. It is unsatisfactory for an advertiser to leave his advertising problems entirely in the hands of an agency especially if his work is professional as is that of the pharmacist. The agency does not as a rule have the professional viewpoint and it is incumbent upon the pharmacist to impress this viewpoint upon his agent and to keep constantly in touch with him and to insist on approving the copy before it is used. Only in this way can technical errors be avoided. An advertising agency may be expert in the technic of advertising but it cannot be expected to be expert in pharmacy. This much at least must be supplied by the pharmacist and he must remain in constant touch with the situation.

The function of the advertising agency is to supply the technical knowledge of advertising. The function of the advertiser is to supply the facts about the business to be advertised. The relationship is similar to that of a lawyer and his client.

Advertising Allowance—The amount of money spent for advertising by retail druggists has been variously estimated and will naturally vary with the type of store that is being conducted. It is safe to say that the amount justified for general advertising should not greatly exceed 2 per cent of total sales and only by carefully checking the results and on indication that a larger expenditure is warranted should more than this be set aside for advertising.

Advertising Mediums—Advertising mediums may take the form of newspapers, magazines, circulars, billboards, signs and cards, letters, window displays, counter displays, theater programs and programs of church affairs, street car cards, calendars, and any other means by which a printed message can be conveyed to the public.

For the advertising of the average retail druggist this list is naturally narrowed to a few of the mediums named while larger concerns may use all of them. Obviously it would not pay the small neighborhood druggist to advertise in a newspaper covering an entire large city. On the other hand, it might be very profitable for him to advertise in a newspaper which covers his section of the city only, or if he is located in a small town where there is a weekly or even a daily paper, advertising in this publication can be made of considerable value. The deciding factor will be the percentage of the circulation of the newspaper which reaches people who are in a position to deal at the store if the advertisement attracts their attention. In a city of a million or more inhabitants it is not uncommon for a single newspaper to have a circulation of some two or three hundred thousand. The advertisement of a neighborhood druggist in such a paper might be read by many of its readers but less than 1 per cent of these readers live within walking distance of his store, consequently, 99 per cent of the amount spent for advertising might be considered waste.

As a general rule it may be stated that newspaper advertising is profitable for the average drug store in a small town newspaper, in a strictly local newspaper and only in the metropolitan newspaper when the store is located in a central section where a large proportion of the readers of the paper are able

to take advantage of the commodities or service offered for sale. The same is true of magazine advertising. It must also be remembered that magazines are usually monthly publications and unless they happen to be purely local publications it would not pay to advertise a single drug store by this means because there could be no satisfactory return. On the other hand for coöperative advertising of all the stores in a state, or in a group of states, the magazine offers splendid opportunities because magazines as a rule are read eagerly and while the reader is at leisure and has time enough to absorb the information given in the advertisement. The educational and institutional type of advertising is therefore well placed in a magazine by groups of pharmacists. Similarly chain stores or organizations of retailers marketing popular articles which are for sale only in certain stores in different cities can profit by advertising in magazines.

Street car advertising may be profitable in the line of cars which passes a store but it would not be profitable when extended to cover an entire city unless the store is located in a central section where it is available to all shoppers while they are "down town". Billboards can be used on roads leading to a town where the drug store is located but in the large cities they are of no special value for the advertising of an individual store. They are of great value in the advertising of drug store products, however.

Show cards and signs used on counters and in window displays are very effective and constitute one of the best advertising mediums of the average store. Advertisements in programs of neighborhood church affairs are considered more or less of a donation. Theater programs are not considered very good advertising mediums unless the store is located adjacent to the theater or in the theater building. Every retail pharmacist has the opportunity to constantly keep before his customers information regarding his service or products by the method of wrapping with each package a circular on something that he wishes to call attention to. Many pharmacists do not take advantage of this opportunity but there are stores in which there is always a supply of circulars on the wrapping counter so that whenever a package is wrapped up a circular is automatically enclosed. Much of this advertising may go to waste but if only one circular out of five, or even ten, is read, it may create a sale or add to the prestige of the store. It is wise to change these circulars frequently and not to depend entirely on manufacturers of proprietary products of one kind or another to furnish all of the circulars used. The opportunity is so good that the pharmacist should really take advantage of it to the fullest extent by preparing his own circulars recommending certain of his own products. It is easily demonstrated that advertising of this kind creates a demand for a product and if the product has merit, it will of course be repeated and talked about and thus gradually acquire a local reputation.

Ready-made circulars imprinted merely with the druggist's name cannot take the place of individually prepared circulars any more than slot machines can take the place of personal salesmanship. Imprinted advertising matter is far better than none at all, but the added effort and cost required for individual advertising matter is amply repaid if any care at all is used in its preparation and distribution.

In a neighborhood community the pharmacist has an opportunity to become acquainted with all of the customers in his territory and this gives him an opportunity to do a great deal of advertising by word of mouth. This opportunity should not be overlooked but even if he does meet his people face to face very often the habit of circularizing the neighborhood either with a printed circular or handbill or by means of a letter is a good one. People who

cannot be reached by the ordinary methods of advertising can be reached by mail. For the price of printing or mimeographing a letter and a two cent stamp one is able to take a message right into the home of the individual and at least call his attention to the contents and discuss business subjects for which the opportunity may never be given in any other way. If this kind of advertising is resorted to it ought to be given sufficient attention so as to accomplish worth while results. Letters should be dignified, not too long, yet long enough to tell their story completely and of sufficient interest to warrant their reading. If the pharmacist makes it a practice to send out a letter once a month to his customers it is quite certain that the first and second letter will be looked over but if there is nothing in them that is worth while, subsequent letters will be thrown in the waste basket very promptly. On the other hand, if the letters get the reputation of having something worth while in them they will be looked forward to and will always command attention. One can judge the habits of the average citizen fairly well by personal action under similar circumstances. Pharmacists are flooded with all kinds of mail advertising in the form of letters, circulars, broadsides, etc., and in practically every case it is possible to mention a few outstanding concerns whose advertising and whose letters are read and even looked forward to while the vast majority are given very little attention. Mail advertising therefore should be given very careful consideration and, if it is indulged in, should be prevented from becoming a waste, by careful study of what people would like to know and what may interest them. A haphazard letter may pull occasionally but for permanent success it is necessary to give this form of advertising the same amount of attention as one would give a customer on his personal visit to the store.

Kinds of Advertising—From the standpoint of the people to whom the advertising done by the pharmacist is directed, we may divide the subject into that which is intended for the general public and that which is intended for physicians, dentists and veterinarians.

Unfortunately, the average pharmacist does very little advertising to physicians, dentists and veterinarians. Usually the proportion of such advertising done varies directly with the amount of professional work carried on in the pharmacy. Pharmacists who are interested in building up their prescription business and making this the main feature of their work naturally do considerable advertising to the medical professions. Others leave this field entirely to the manufacturing pharmacists and their detail men.

Detail Work with Physicians—The modern method of keeping physicians informed of the advances in therapeutics, the marketing of medicinal products, etc., is to send a representative, known as a detail man, to the physician and thus give him first-hand information about the composition and merits of the product and the relief following its use. Such detail men must establish their identity with the physician and gain his confidence before they can make very much headway. It would seem therefore that the local pharmacist who has every opportunity of coming in daily contact with physicians would have a much better opportunity of acting as his own detail man for U. S. P. and N. F. products than the representatives of manufacturing houses, but it is also true that the average retail pharmacist does not take the time to do this. Physicians can be educated to look upon the pharmacist as their source of information instead of upon the literature and talk of the traveling detail man. Naturally, the pharmacist who attempts to do this kind of work must keep himself informed constantly of the developments in medicine and pharmacy, but he will find

that, once his physicians realize he has such knowledge, they will become his very warm friends and patrons.

Supplementing the personal visits of the pharmacist to explain and to give information on U. S. P. and N. F. products as well as on his personal service there should be periodic letters, on topics of interest designed to keep the physician informed of what the pharmacist has to offer in the way of improved prescription service, etc. Manufacturers will frequently offer to send letters on the pharmacist's letter head to a selected group of physicians, advertising the pharmacist and at the same time calling attention to the fact that he has in stock certain preparations which the manufacturer may be exploiting at the time. In such cases the pharmacist should insist on seeing the letter before it is sent so that he will not be called upon to endorse anything blindly. The manufacturer, of course, pays the expense of preparing and mailing the letter, the only expense to the pharmacist being the cost of his letterheads and envelopes.

Advertisements in weekly or monthly bulletins of local medical societies are helpful. They identify the pharmacist at once as one who is interested in cultivating the acquaintance and patronage of doctors. A pharmacist who is interested in developing his prescription service should read the *Journal of the American Medical Association* and, perhaps one or two other good medical journals so as to keep himself informed of new developments in therapeutics and pharmacology. It is good advertising to be able to speak to the doctor about new medicinal preparations, knowing the angle from which the subject was treated in the publications which the physician himself reads.

Giving physicians a percentage rebate on prescriptions or presents of various kinds in exchange for their help in building up the pharmacist's prescription business is contrary to the Codes of Ethics of both professions and the codes should be followed to the letter on this point (see page 9). There is no harm in occasionally presenting a physician with something as an expression of goodwill or in allowing a reasonable reduction in price on items for his personal use, but it is not necessary or proper to sell things to the physician at factory cost without figuring in the pharmacist's overhead. That would really be selling the item at a loss and no one is expected to do that.

It should be remembered at all times that the physician is a busy man and that even those who are most favorably disposed toward the pharmacist personally, cannot be expected to carry in mind the details of the latter's service. This can only be fixed in his mind by the results which he sees or hears. Constant reminders are therefore not out of order but really necessary.

Advertising to the Public

In his advertising to the public the pharmacist should feature service rather than price on articles of merchandise as well as on drugs and prescriptions. The "service buyer" is always more valuable to the store than the "price buyer". It is true that chain stores and other organizations located in transient sections feature price and often cut the prices of standard nationally advertised goods so low that the average pharmacist cannot compete with them. It is best not to try to compete with chain organizations on the basis of price but to turn the attention of the customer in an entirely different direction, namely, that of service. Independent pharmacists who have succeeded in attracting public attention to their service are rarely bothered with the price question. Where there are so many side lines it is difficult to adopt a general policy that will fit all departments, but a few general rules can be laid down.

Service is intangible but none the less real. It is the force which draws

people to one store in spite of the attractions of competitors. It may express itself in a passion for cleanliness and order in the store. Attentive, well mannered and well informed employees give a store a reputation for service. Prompt deliveries by intelligent messengers accomplish the same purpose. A willingness to pass the time of day with sociably inclined customers also helps. A stock up to date and constantly supplemented by new merchandise is a compelling factor. In fact, the customer's sentiments about service can be summarized in the following sentence, "I like to trade at Blank's because they have such a nice store and are always so pleasant and you can always depend on them to have what you want." A store with a sufficient group of customers expressing sentiments of that kind has little to fear from unethical competitors.

It is not desirable for the average pharmacist to advertise "ready made" medicines too strongly if he expects the coöperation of physicians. Physicians are opposed to self-medication and rightly so. They do not object to the featuring of household remedies as has been well demonstrated in a recent national advertising campaign by a pharmaceutical manufacturer, but they are opposed to the general endeavor of medicine manufacturers to create the impression that every ailment can be cured by some concoction of drugs. Good professional practice requires that not only the attitude of physicians but the ethical basis of such procedures be taken into consideration and that nothing offensive shall be displayed or otherwise given great prominence in the pharmacy.

The pharmacist must bear in mind that in many national advertising campaigns he is at the end of the chain which is expected to link the public with the manufacturer. A national advertising campaign will be unsuccessful if the product advertised is not available or if it does not have the support of the dealer who sells directly to the public. Many a good product has been a business failure because of lack of coöperation on the part of the retailer and some mediocre articles have acquired national prominence because of the support given them by the dealer. The pharmacist's judgment as to whether to support or withhold support from a national campaign should be based on the quality and utility of the product rather than upon its profit possibilities exclusively. He should not permit the use of his name in promoting it unless he is sure that the preparation has merit.

The pharmacist must always remember that the people who trade at his store are *his* public and that if he does not cultivate their goodwill and establish his identity with them he will simply be known as a dispenser of nationally advertised products and a convenient source of a large variety of goods. No national advertiser can establish a reputation for an individual pharmacist. This he must do himself and for that reason he must prepare and issue a certain amount of advertising of his own in which he and his service are the central themes. The methods of advertising to the public have been discussed to some extent under the various advertising mediums in foregoing paragraphs, and it has been pointed out that advertising by means of circulars and other literature wrapped with packages and an occasional personal letter are very effective for the average store.

Mailing Lists—In order to carry out such individual advertising, the pharmacist should have an up-to-date mailing list of the people in his vicinity. Such a mailing list can be obtained from a register of voters in the election district, from city directories, from organizations which make a specialty of supplying such lists, or it can be built up by the pharmacist himself. The latter procedure is somewhat tedious but it is perhaps the most satisfactory. It

will insure that the mail or other matter goes directly to people who are interested. The pharmacist starting out in a new neighborhood can request his customers to fill in a card giving name, address, telephone number, etc., on the pretext of wishing to keep the name on file for deliveries or for the mailing of something desirable in the way of a gift. A contest of some kind can be run which will require the participant to fill in an information blank at the same time that a guess is made of the number of pills in a large container or the weight of some substance. There are many other forms of contests which have been devised from time to time to attract attention, and arouse interest and they accomplish much for the pharmacist who has only a limited sum to spend for the information which he will receive as a result of such a contest. Once the mailing list is obtained, it is well to divide it into male and female groups so that if information is to be sent out on face powder, for example, it will go only to the women in the group, and if cigars are to be the subject of a letter it will only go to the men. A close watch should be kept on the new arrivals in the neighborhood, not only from the standpoint of being able to give information on this subject but that the new people may be given some sort of a welcome, personal if possible, and if not, at least by means of a letter telling about the neighborhood store and how it serves the community.

The distribution of samples of products that are for sale is good advertising, provided the samples are placed in the hands of the proper people. Samples of drug products, for example, should never be handed to children. On the other hand, samples of toilet preparations or confectionery are very welcome and can be distributed quite indiscriminately with good results. The use of trading stamps and premiums as well as rebate cards recording the sale of certain quantities of merchandise and allowing credit for a given percentage of the amount spent, are very valuable in certain cases, but wherever there is a premium of any kind offered people are apt to suspect that it is made up in some other way at their expense. This is, of course, true. No merchant can afford to give away something for nothing. Wherever this seems to be done the merchant actually goes to some expense. That expense may be charged up to advertising. It is a question whether the same amount of money spent in more legitimate advertising would not bring as great a return in the long run.

Window Displays—Window displays are, of course, among the best advertising mediums which the pharmacist possesses. The window has been called the "eye of the store" and it can have a great influence on the success of the business. Some pharmacists have a reputation for always having attractive windows and their displays are the talk of the neighborhood. In transient sections window display space is often rented out to manufacturing concerns who wish to popularize something by means of a demonstration or an attractive display, and in such cases the pharmacist should be very careful that the display is one which he can conscientiously endorse and which will not in any way interfere with his professional standing. There is nothing wrong in renting out window display space to those who want it and very often it helps considerably in meeting the expense of the establishment. However, this should not be done to such an extent as to interfere with the individuality of the store. The art of window dressing is one at which many spend their entire business lives and much useful information may be obtained from books on advertising, by studying the displays of large department stores and other concerns where experts dress the windows or by taking a special course in the subject.

The first impression made on the passerby by a pharmacy is created by the appearance of the windows. If the windows register friendliness, cleanliness,

quality, dignity, or beauty, the impression will naturally be favorable. If on the other hand, they register slovenliness, carelessness, filth, cheapness, or ugliness, the impression is decidedly unfavorable. The favorable qualities can be provided readily.

One of the chief functions of the window is to attract attention. There must be some feature which will cause the casual passerby to observe the window. This may be brought about by special lighting, attractive and unusual colors, a special sign, a moving object or a living object. Many features will suggest themselves to anyone who is actually engaged in "dressing" a window.

Window lighting and construction have already been discussed on page 1313.

No display will attract more attention than a moving object—especially if there is some mystery about it, such as the continual flow of liquid from a bottle, but most attractive of all is the introduction into the window of a demonstrator, who carries out an operation requiring special skill.

After attracting attention, there must be some central feature of the window on which the attention of the passerby is focused to the extent of converting his interest into a desire to own the article advertised. If the window fails in this it is not 100 per cent effective. The window decorator should be his own most severe critic. He should mingle unobserved with the people who are attracted and listen to their comment. Many a valuable suggestion is thus gained. Of course the articles displayed should be seasonable, reasonably priced, and of a nature to make an appeal to a large percentage of those who pass the store.

The following suggestions are taken from the "Calendar of Seasonable Window Displays" printed in the *N.A.R.D.* Journal:

January—Clinical Thermometers—Hot-water Bottles—Prescriptions—Atomizers—Soap—Sick-room Supplies—Garden Books—School Supplies—Camphorated Oil.

February—Cough and Cold Medicines—Lincoln's Birthday (special)—St. Valentine's Day (special)—Chest Protectors—Tooth Brushes and Dentifrices—Corn Remedies—Garden Seeds—First-Aid Packets—Candy—Medicinal Soaps—Spirit of Peppermint.

March—Wall Paper, Paint, Brushes—St. Patrick's Day (special)—Manufacturing Display—Sponges and Chamois—Housecleaning Helps-Stationery—Veterinary Remedies—Condition Powder—Bird Seed—Fish Food and Aquaria—Solution of Magnesium Citrate.

April—Varnish—Outing Goods—Easter (special)—Perfumes—Toilet Preparations—Cameras—Dog Remedies—Dye Stuffs—Combs and Hairbrushes—Skin Lotions—Cleansing Preparations—Borax—Soda Fountain Opening—Clean-up Week (special).

May—Thermometers and Barometers—Decoration Day (special)—Medicinal Herb Display—Insecticides, Paris Green and such—Olive Oil—Fountain Pens—Fly Paper—Food Products Exhibit (tea, cocoa, honey, gelatin, maple syrup)—Moth Balls, Camphor—Baby Week (special).

June—Vacation Needs, Toilet and Medicinal—Cameras and Supplies—Soda Fountain—Flag Day (special)—Nursery Supplies and Baby Foods—Seidlitz Powders—Razors and Strops—Outing Goods—Liniments—Fishing Tackle.

July—Talcum and Face Powders—Fourth of July (special)—Stationery—Prescriptions—Cigars—Spraying Apparatus and Sprays—Rubber Goods—The Leading Advertised Summer Merchandise—Skin and Freckle Lotions—Rat and Roach Killers.

August—School Supplies—Soda Fountain—Old Home Week (special)—Spices and Flavors—Fly Paper—Soap, both Toilet and Laundry—Shoe Polishes and Clothes Cleaners—Talking Machines—Souvenirs—Trusses—Remedies for Summer Ailments—Insect Powder.

September—Labor Day (special)—Fair Day (special)—Tooth Brushes and Dentifrices—Novelties—Hair Tonic—First-Aid Packets—Paraffin Wax and Canning Specialties—Shaving Paraphernalia—Corn Remedy—Candy—Manicure Goods—Bath Supplies—Honey.

October—Columbus Day (special)—Hallowe'en (special)—Crêpe and Tissue Papers—Books and Magazines—Farm Supplies and Remedies for Fall and Winter—Prescriptions—Gymnasium Supplies—Cosmetics and Grease Paints—Hot Drinks—Soaps—Olive Oil.

November—Rubber Goods—Election Day (special)—Thanksgiving Day (special)—Stationery—Special Winter Remedies—Chest Protectors—Shoe Insoles—The Leading Advertised Winter Merchandise—Liniments.

December—Cigars—Candy—Games—Christmas and New Year's Cards—Perfumes—Christmas (special)—Flavoring Extracts—Musical Goods—Toilet Articles in Sets—Toilet Sets—Gifts—First-Aid Packets—Talking Machines—Cold and Cough Remedies.

A desirable addition to any display is cards (see page 1384), giving the price and other information in a few terse sentences. This has proved to be important, as often a prospective customer is fearful that the price will be prohibitive, and no matter how attractive the display, he will not come in and ask the price for fear of the embarrassment that would follow his not buying on account of the high price. Again drug store merchandise often requires a word of explanation to make it suitable for display. A small auxiliary display of the goods shown in the window should be arranged inside the store near the entrance so that the passerby who has been attracted by the window will see the same thing when he comes inside and can go to it immediately for his purchase.

Displays of a single item are best because they do not distract attention. However, the modern store window is so valuable that it becomes necessary very often to display several articles related to each other and sometimes even unrelated articles. By building up such displays in sections and making them sufficiently attractive so that they will not appear jumbled, several items can be advertised at once and the number of chances of attracting people are multiplied. When there is a mixed display, it is well to focus attention on some central idea, price or product for the purpose of carrying the passerby beyond the point of interest. Once a passerby has been persuaded to come inside of the store the salesmanship there displayed will decide whether he will purchase something in addition to what he came for. Very often the lure of a sample or a small gift with a purchase, or a bargain price, or an especially attractive article will induce people to come into the store.

Planning the Window—Before starting to decorate, the window should be planned, at least roughly. This may be done on paper. The goods that are in stock will largely determine the display. Many firms are offering special window display material with their goods. Such material will usually add to the attractiveness of the window, but must be used with discretion, for it may not conform with the ideals of the store.

Several fundamental things about the show window must be right. The window glass must be clean, and if there is any tendency for the window to "sweat" this must be corrected. Sweating, and in cold weather, frosting, are caused by the air inside of the window being warmer than that on the outside. It may be remedied easily by drilling holes in the bottom of the window, below

the glass, and also at the top, above the glass, so that air from the outside may circulate. In modern store construction this equalization of temperature is taken care of in the building of the show window.

The rear of the window should be closed by means of glass doors or frames. This is important, as the window can easily become dirty from dust of the store if it is not enclosed. The enclosure should be of glass or the storeroom will be unnecessarily darkened. Provision should also be made for preventing direct sunlight from reaching the interior of the window by the use of shades or awnings. Sunlight will quickly injure candies, rubber goods, fine packages, decorations, etc.

Everything that goes into the window should be attractive. The bottom of the window should always be raised six to eight inches above the lower edge of the glass. Supports should be used to raise the display from the bottom of the window. These need not be expensive; small bamboo stools are especially useful when combined with shelves of plate glass, enabling the building of a pyramid, which gives one of the most attractive forms of display. The same stools and plate glass may be used in many other combinations. Wooden boxes of assorted sizes are also useful and may be permanently covered with burlap or other material. Ready made display units of various kinds are also on the market.

There should be no hesitancy in spending a part of the advertising money for draperies, or for coverings for the bottom of the window. Crêpe paper in attractive colors may often be used. Cheesecloth can be bought in many shades and can be arranged to give good effects where the windows are not too large, and the grade of the merchandise offered for sale justifies the expense. More costly cloths, even velvet, are often used for special displays, such as perfumes.

Harmony in the color scheme should be kept in mind and if the color combinations in natural flowers are observed, no better guide can be secured for perfect harmony. The draperies, or other hanging materials, if inflammable, should be fireproofed by the use of a fireproofing solution. This is especially important if cotton is used in the window for Christmas or Easter display. Many serious fires have started in display windows.

Sodium tungstate solution, or a solution made according to the formula given below, may be sprayed on the material to render it fireproof:

Ammonium Sulphate	8 lbs.
Ammonium Carbonate	25 lbs.
Boric Acid	3 lbs.
Borax	1.7 lbs.
Starch	2 lbs.
Water	12 gal.

One cardinal principle which the window trimmer should always keep in mind is that whatever story the window is designed to tell it must "get over" instantly into the consciousness of the passerby, as it takes but a few seconds to pass the window and usually there is but a fleeting glance bestowed upon its contents.

A window display which is crowded will fail to give this effect. It is better to have a smaller display, but attractively arranged, than to crowd the window so that no one thing stands out prominently.

Windows should be changed regularly—at least once a week—and special occasions, such as holidays, local events, and seasonal occurrences should be taken advantage of to make appropriate displays. It is well to make this the

duty of one man in the store, who will work out the details, following the policy and suggestions of the management. Frequently some clerk will be discovered who has special abilities along this line, or can be induced to make a study of it.

Factors to be Considered in Writing Advertisements

While this chapter cannot take the place of a course in advertising writing and is not intended to do so, it would probably be considered incomplete without some detailed discussion of the human factors which must be kept in mind in addressing an appeal for business to the public. In previous paragraphs some of the mechanical details of the production of an advertisement have been discussed. We now come to the actual writing. What is it that makes one piece of advertising copy "pull" and another "fall flat"? The answer to this question is constantly keeping the advertising writer on his mettle. When the cost of space runs into thousands of dollars it is necessary to say something in that space and in such a way that it will be read and bring action and thus make the expenditure bear fruit. The pharmacist's problem is the same, only on a smaller scale. Usually the first thing which must be done is to forget professional language when addressing an advertisement to the public. In preparing advertising for physicians the technical language is not objectionable although the chances are that of two advertisements of equal merit, as far as context goes, the one written in the simplest language will "get over" more effectively even with the physician. With the public it is axiomatic that the more simple and direct the language the easier will the advertisement be understood and the quicker will it produce results.

The story is told of how an advertising writer asked a chemist in a soap manufacturing concern to give him a short paragraph about the virtues of a particular soap that was to be advertised to the public. This is what the chemist wrote: "The alkaline element and vegetable fats in this product are blended in such a way as to secure the highest quality of saponification along with a specific gravity that keeps it on top of the water, relieving the bather of the trouble and annoyance of fishing around for it in the bottom, during his ablutions."

When the advertising writer got through with this statement and passed it on to the public, it consisted merely of the two now well-known words: "It floats".

It is this ability to boil things down to the essentials that is so necessary for successful advertising today. With thousands of products vying for public attention through the printed word there simply is not time enough in the life of the average human being to read a long story. A few striking words, a catchy phrase, an outstanding illustration—these are the things that get over. One has only to look at the billboards, street car cards, and magazines and newspaper advertisements to realize that the "big sellers" are advertised with striking illustrations and short pungent sentences, paragraphs, or slogans.

To portray the essentials in this manner is no easy task. It represents the hardest kind of work. Horace Greely, the noted editor, was once asked to write a short editorial on some subject of popular interest and he replied that he did not have the time to write a short editorial. He could readily produce a long one but the short one would take much more time than he could afford to devote to it. The same is true of advertising. The short, smooth, well-rounded and appealing phrases of the professional copy writer are not "just dashed off". They are the result of condensing and recondensing longer statements and of patient effort in selecting words of the proper shade of

meaning, yet understood by the average twelve-year intelligence, which, psychologists report, represents the average of learning of the American public the country over.

The Appeal—Assuming that the one who is to write an advertisement has obtained all of the facts upon which to base the copy there must of necessity be a selection of those which are most important. Judgment as to which are the most important facts depends in the first place on the public that is to be reached. If the advertisement is to be written for men, or for women or for children, respectively, it will be different than if it were written for all three groups, so it might well be said that, after the gathering of the facts, the next most important thing in the preparation of advertising is to determine to whom it is to make its appeal. Having decided on this point it is necessary to bear in mind the peculiarities and the viewpoints of each particular group of people and to lay the proper emphasis on the points which will appeal to them. This involves a study of the habits, customs, reactions and viewpoints of men, women, and children, and long experience in dealing with these groups in the daily contacts of the drug store is a valuable asset here. The important thing to remember is that the writer of the advertisement must not get the idea that a statement which would convince him, an argument which would to him sound entirely logical or which he could easily comprehend, will have the same force, logic, and conviction with a woman buyer or with a man who is entirely uninterested, or with a child. Trying out the copy on representatives of the types to which it is to appeal is a very valuable aid in this work. The more critical the test individual may be, the better for the writer of the advertisement, provided the criticism is constructive.

Types of People—It is also important to bear in mind that people are more or less easily classified into groups based upon their habits of buying and their methods of acquiring knowledge or information.

It is not difficult for one who has been in contact with people to recognize three distinct types as far as buying is concerned. There is one group which acts entirely upon its own initiative. An individual belonging to this group will consider the merits of a product and make his own decision independently of any other individual. He is of the type which will originate things. He is not afraid to try something new if it makes an appeal to him. For lack of a better name we might call this group the initiators, those who do things before somebody else does them or in spite of what somebody else does. The "initiators" are, of course, a minority group. Advertising copy of the kind which explains the usefulness of an article and the technical reasons for its superiority will appeal to this group.

Every business man recognizes immediately the very large percentage of buyers who are influenced by what others say, or do, or wear. All you have to tell this type is that the style this year is so and so and they immediately accept that as final and regulate their buying accordingly. This is the group which is influenced by the testimonial type of advertising. If some social leader or the wife of a prominent national politician uses a certain face cream this group will use the same product, not because they have investigated its merit but simply because they imagine that the use of the product puts them in the same class with the prominent person who is advertised as using it. The advertisement in national magazines and newspapers of the testimonial type, whether they be the cheap testimonial letter of the sufferer in some small town who has been cured of ailments by taking a bottle of some advertised remedy, or the respected preacher or school teacher who has been benefited by eating three cakes of

yeast a day, indicate the effectiveness of this kind of advertising. It is nothing more than taking advantage of the fact that most people regulate their habits and their activities by what the large majority are doing. They are not initiators but followers. The terms "proved safe by millions", "thousands of users in all parts of the world", "has been used for twenty-five years", etc., so familiar in various advertisements are simply a recognition of the great influence exerted upon the majority of the people by what the mysterious beings known as "they" are doing or saying.

There is a third group which, like the first, is a minority group. This group neither initiates nor does it follow the example of others immediately. It is a more conservative group than the second. It waits until things are definitely proven and settled. It does not take kindly to anything new. It looks with skepticism on the things that the majority do until such time as it is satisfied that what the majority is doing is really a good thing. This group must be convinced, not only by the attractiveness of a package, not only by the utility of an article or the low price, but by conclusive proof that all of these attributes really make the product worth possessing; then they will buy.

It is plain to be seen that advertising which is to have a value with all the people must contain statements that will carry conviction to the various groups just enumerated. In the case of new things, it is most important to attract the first group. If they are convinced and begin to use the product they furnish the basis for methods and statement which will attract the larger second group. In other words they become the mysterious "they" group. "*They* say it works all right." "*They* say it is a good show", etc., are the comments which spell success for the advertiser. The third group will come along in good time and even if they never come, the advertiser's success will be insured if he can get the first two.

Another way of grouping people from the standpoint of absorbing knowledge of products or reacting to advertising is very similar to the general grouping of students from the standpoint of teaching at colleges and schools. Educators recognize the type of student who learns best by hearing his instructor explain the topic. Another learns best by studying from a text, that is, by reading and seeing things in print. A third type learns best by actually doing things. This has given rise to the threefold method of instruction followed in the colleges, namely, lectures and recitations, textbook study, and laboratory work. Every student learns something by all three methods, but every student also learns best by one of the three. People in all walks of life are very similar. Some will be convinced by the talk of a good salesman, others like to read about a product and make up their minds as to its value on what they see on the printed pages of a circular or booklet. Still others can be convinced only by actually handling the product; they are unable to visualize its advantages from a mere talk or a printed description; they must see it and handle it in order to be convinced.

The writer of advertising, knowing that people fall into these groups will not only describe his product, but will issue an invitation to the reader to come and see the thing being advertised and offer to let it be tried. He will also offer to send a representative to explain the proposition. In this way the entire group is covered through printed advertising. Those who are convinced by the printed word alone will buy at once; those who prefer to talk it over with someone have the opportunity of signifying that fact, and those who want to handle the product are told that they can do so if they wish.

The writer of advertising must also remember that a definite fraction of

every income must be set aside for the necessities of life, including food, clothing, and shelter. If there is a balance after these necessities are provided for it may be spent for what are considered luxuries. A decision must be made as to whether the product or service advertised comes under the head of necessity or luxury. When one is advertising a necessity, the utility of the product, its economy, and its value can be stressed. When one is advertising a product that will appeal to the "free dollars" of the public rather than to their "mortgaged dollars" the appeal will be entirely different. Pride of possession, the distinction of ownership, and the pleasure to be derived from its possession are points which may be stressed.

Medicines, dental preparations, prophylactics, etc., are classed as necessities but many if not most of the articles now sold in the pharmacy, do not come into the necessity class.

The writer of advertising for drug store merchandise can resort to a range of appeals almost as wide as the variety of merchandise he offers for sale. He may attract the reader by the utility of an article. He may stress the environmental appeal in which location, climate, or custom will be featured to attract attention and create desire. He may appeal to the senses, emotions, and instincts, such as touch, taste, smell, sight, sound, happiness, sorrow, love, self-preservation, curiosity, economy, and beauty. It is not difficult to think of various kinds of modern drug store merchandise which can be sold by an appeal to any of the foregoing senses, emotions and instincts.

Appeals may be made to the imagination of the reader but such appeals must not take too much for granted. Very often they miss their mark because they assume too great an average intelligence.

Appeals involving memory tests, and advertisement or slogans set in rhyme, while very attractive, do not as a rule make lasting impressions. The public memory is remarkably short. Only by constant and frequent repetition are pertinent facts, names, or illustrations kept alive.

Association of advertising with news of the day, with the seasons, or with national events tends to emphasize it and should be taken advantage of at every opportunity. Linking the unknown to something already well and favorably known facilitates the progress of the former on its journey into the consciousness of the individual.

The habits of a community play a large part in its reactions toward various advertising appeals. A knowledge of these habits is a great asset in formulating the appeal. Habit is a rigid master over its human slaves and it is far from the line of least resistance to endeavor to break down habits in an effort to popularize something.

In recent years the policy of "satisfaction or your money refunded" has been in vogue almost universally. Starting with mail order advertising it has gradually permeated all forms of advertising and is either stated or implied wherever an effort is made to sell anything through advertising. This has in a large measure restored confidence in advertising.

The use of illustrations to convey in an instant the story of products which it would take many hundreds of words to tell is to be commended and the use of color is likewise an asset.

Enough has been said on this subject to indicate that the writing of successful advertising requires a fair knowledge of human nature, a knowledge of the workings of the human mind and its reaction to various stimuli, and most important of all, an intimate knowledge of the subject upon which one is writing.

SALESMANSHIP

Knowledge of salesmanship is essential for success in every line of endeavor. It has already been pointed out in this section that every professional man as well as every business man has either a service or a commodity to sell and his material success depends upon his ability to sell these to the greatest advantage.

Much of what has been said in the chapter on advertising applies with equal force to selling because advertising, after all, is a method of selling. The classification of minds, the classification of people according to habits of thought, customs, and reactions to various stimuli is just as applicable in sales work as it is in advertising. In selling, the salesman usually faces a customer and talks to him directly rather than at long distance. Circumstances and individuals must be "sized up" in a selling interview and the right thing must be said at the right time. In direct sales work the personality of the salesman cannot be hidden behind a screen of clever words or striking illustrations. It stands out by itself either to make or break a business transaction.

Selling involves three factors, namely, the salesman, the goods or service offered for sale, and the buyer. The goods and service sold in a pharmacy have been discussed in another chapter. The buyer has been discussed at length in the chapter on advertising. He is the average citizen who comes to the pharmacy for his needs. He is the same individual to whom we address our advertising appeal. There remains for discussion the salesman and his methods.

In the one-man pharmacy the proprietor is, of course, the only salesman but as the store grows and becomes departmentized, the selection of a proper sales personnel becomes one of the most important duties of the management. A pleasing personality is most desirable. The ordinary attributes of honesty, sincerity, willingness to work, a certain amount of ambition and loyalty are essentials. Many of these essentials can be cultivated and improved in the sales person after he joins an organization. His personality is, as a rule, fixed and difficult to change. The proprietor should set an example to his sales force in matters of cleanliness, neatness, promptness and in the courteous treatment of customers. These are absolute essentials for successful selling.

It has frequently been said that good salesmen are born and not made. This is true to a certain extent but it is also true that those who do not have natural selling ability can cultivate it by careful application and self-analysis. Very often one who has conscientiously and carefully studied the underlying principles of salesmanship will surpass a so-called natural born salesman in his record of efficiency. This is due to the fact that those with natural ability often neglect to keep abreast of the times and refuse to take advantage of the opportunity afforded for increasing their knowledge of salesmanship. Natural born salesmen are apt to have whims and fancies. They work when the spirit moves them and wait for inspirations. The ordinary salesman who is constantly working to improve himself and to increase his ability takes advantage of all opportunities, studies the underlying laws and principles and applies them persistently and consistently whenever possible. His methods may be crude at first but they become more polished with experience.

In some cases selling constitutes merely taking or filling orders. If a sales person hands out a package of something that has been asked for, he is making a sale but he is not necessarily a salesman in the modern sense of that term. If, however, he is asked for an article and he sells something to the customer that has not been sold before, or if he sells a better article than the customer intended to buy, or if he sells something to the customer which the latter has

previously bought somewhere else, or if he sells more of an article than the customer originally intended to buy, then he is practicing salesmanship. To do this the salesman must be a convincing talker. He must have the power of persuasion. He must inspire confidence in the buyer. He must be able to tactfully overcome prejudice and obstacles to a sale, and finally he must retain in practicing all of the arts enumerated, the goodwill of the customer. If, by selling more than the buyer intended to purchase in the first place, the buyer is antagonized and avoids the store in the future, the salesmanship has been detrimental rather than helpful. If, by selling the buyer an article of better quality than he intended to buy, the latter leaves with the conviction that a service has been rendered him because of the greater lasting quality of the article and its consequent economy, the salesmanship has been successful. A salesman can very easily overplay his rôle and instead of making friends for a store create enemies. Constant vigilance on the part of the proprietor or manager is necessary to enforce the selling policy established for a store. It is necessary to thoroughly train new clerks in the sales policy of the store and impress them with the fact that they represent the proprietor in their contact with customers and that they must not let their personal likes and dislikes govern their attitude toward buyers.

Commissions—In order to keep up the interest of the sales personnel in achieving a greater sales volume, it is common to add a commission or bonus to their salaries based on personal effort in disposing of a particular class of goods. Usually the specialities offered are made subject to such commissions. This has the effect of stimulating the sales person to make an effort to dispose of some of this class of merchandise, but care must be taken that no unfair and detrimental methods are used in an endeavor to have the customer purchase the specialty rather than some other product which is really wanted. The percentage of commissions allowed on sales varies with the class of merchandise and the normal volume of business done.

Sales Personnel—For the prescription and drug department, registered pharmacists and college men who are studying pharmacy should be given preference. The salesmen or clerks in the departments must be able to talk intelligently about professional matters. It is very unsatisfactory to place people without proper knowledge of drugs behind the drug counter. At the soda fountain or cigar case or at perfume and toilet goods counter or in the stationery department and elsewhere, it is not necessary to employ people who have studied or are studying pharmacy, but they in turn should know the merchandise which they are selling. It should be insisted upon that they make a study of it and instructions should be given them not only as to which are the profitable items, but what are the merits or defects of each item in the list. In a large store there will of necessity be a mixed group of sales people and it is necessary to establish harmonious relations between them and to cultivate a spirit of loyalty toward the management.

Exclusive Agencies—When it is possible to secure exclusive agencies for good advertised lines this should be done. An individual retail store can often profit greatly from the prestige enjoyed by advertised goods, not only through sales of the advertised articles, but also by other sales made to customers thus attracted to the store. An effort should be made to supply the customer with exactly what he wants. The practice of substitution of inferior but more profitable merchandise for standard advertised products is to be condemned. If the nationally advertised article is not sold at a profit there is, of course, good reason for wishing to sell something else in its place, but even if there is little profit in the thing asked for, it should be supplied on demand. If the

customer gives the salesman an indication that he wants something like a nationally advertised product and the pharmacist has something that is really more valuable, or at least as good, there is no harm in offering it, but no deception should be practiced. The transaction should be to the interests of both buyer and seller.

Profits—In previous chapters selling expense has been considered in connection with the pricing of merchandise. There are still some merchants who cling to the belief that everything they take in over and above the actual cost of merchandise is profit, in spite of the fact that it costs considerable money for rent, light, heat, clerk hire, and for their own maintenance. These expenses are usually grouped under the heading of overhead and it is axiomatic that the actual cost of an article is the amount paid for it plus the overhead. Anything above the sum of these two figures is considered profit. The terms "gross profit" and "net profit" have been used in the past. Gross profit is supposed to be the amount received for an article from the buyer, less the cost paid to the manufacturer or wholesaler. Net profit is the term applied to the difference between the amount received from the buyer and the sum of the cost of the article plus the overhead. More recently the term margin has been employed to indicate what was formerly known as gross profit. The term gross profit is no longer used in modern accounting. It really has no meaning as far as actual profits are concerned. Whether the percentage of margin or net profit is figured on the cost or on the selling price of an article does not make very much difference but it is important to know whether or not a transaction yields a net profit or margin. The fallacious method of figuring profits so commonly met with among business men is in all probability based on problems still found in the common school arithmetic books which assume, for example, that when an article costs $2 and is sold for $3, the profit is $1. Nothing is further from the truth because it is necessary to add to the cost of the article which is $2, a definite sales cost which may be a very large portion of the $1, that is assumed to be all profit. It seems to be a difficult matter to disabuse the mind of the average young man who goes into business of this faulty mathematical calculation of his primary school days.

Modern Selling—In recent years selling has assumed an aspect that is entirely different from the views held fifty years or more ago. We have graduated from the period of haggle and barter to a period of fair and fixed prices; from tricks of the trade to open square dealing; from the attitude "let the customer beware" to "let the customer be satisfied"; from the closed deal to "money back if you want it"; from merchandise of uncertain quality to guaranteed merchandise; from misleading labels to correct marking and branding; from advertising bombast to accuracy in word and print; from the dingy shop to the attractive and well-lighted store. All of this means that a new type of salesmanship has been born and is constantly being developed. Sharp trading is taboo. Honesty is indeed the best policy.

Price Cutting—Various schemes have been used in an endeavor to appeal to the "something for nothing" instinct of the average citizen for the purpose of increasing sales. One of these schemes is price cutting. Merchants who have been unable to draw trade away from established dealers on competitive service often attempt to do so by reducing prices. Stores located in transient neighborhoods frequently offer well-known nationally advertised products at or near the wholesale cost in order to attract trade. In other words, they advertise these items for sale at an actual loss, for, when an article is offered at less than the sum of its cost plus the cost of selling it, every sale of that article means an actual loss of money. The theory on which these cut price sales are

based is that people are attracted because of the low prices of advertised articles and thus get the general impression that the store is one at which low prices prevail on all goods. It is natural for the public to want to buy things at the lowest prices. The public does not reason far enough to understand that whenever the store loses money on one item it is necessary to make it up on another or go out of business and that the cut prices are merely a bait to draw them into the store where, if possible, they will be sold more profitable merchandise.

An occasional sale of shop worn merchandise, or of a large volume of some popular article at a price somewhat below the regular selling price is not objectionable but continual sales of leading articles at prices which mean an actual loss, just for the purpose of attracting trade and selling them something else is neither fair nor honest. The retailer who employs this method of attracting trade is really using the reputation and goodwill built up by others through national advertising for his own selfish ends without rendering any service excepting, possibly, to hand over a package of the advertised article when it is insisted upon. It will be found that in stores where advertised merchandise is sold at cut prices the clerks are instructed to sell substitutes for these articles whenever possible, thus making a profit for the store. It is well realized that if the advertised article were sold at the cut rate there would be a loss. Manufacturers of advertised merchandise are beginning to learn that the goodwill of the dealers toward their products is being jeopardized on account of the price cutting evil and that it is becoming harder for them to sell to the public because of the lack of coöperation of retailers who naturally would rather sell something on which there is a fair margin. They are therefore making an effort to control the resale price. There has been legislation before the Congress of the United States for a number of years, the purpose of which is to compel the selling of articles at prices printed on the package so as to assure fair competition. Such legislation, commonly referred to as price maintenance legislation, has been opposed by many large manufacturers but has the unqualified support of numerous retail organizations. Recently many manufacturers have declared themselves in favor of price maintenance. As a matter of fact, it is possible for a manufacturer to exercise some control over the prices at which his merchandise is sold without any new legislation. He can refuse to sell to the persistent price cutter. No one can compel him to sell to anyone if he does not care to do so. Certain well-known manufacturers have followed the policy of restricting sales for a number of years and have been sustained in their action by decisions of the United States Supreme Court.

Recently there has been a concerted effort on the part of retail druggists' organizations in some sections to force manufacturers to become active in maintaining resale prices. These organizations issue "courtesy cards" to salesmen of concerns, which, upon investigation are found not to offer special discounts to chain store organizations or department stores, and who do not sell to price cutters and otherwise protect the retailer's interests. If a salesman wishes to do business with a retailer belonging to the organization and does not have the "courtesy card," it is supposed to be notice to the retailer that the salesman's firm is not in sympathy with the retail organization's interests. It is claimed by some that such procedure on the part of the retail druggists' organization is in violation of the laws of the country with regard to restraint of trade but others believe that there is no violation of law in the scheme. It is a question that will undoubtedly be decided at some time by the Federal Trade Commission or by the courts.

Special Sales—In recent years there have come into existence, in our large cities, organizations known as "Better Business Bureaus". These organizations are maintained by advertising associations and others interested in retaining public confidence in sales propaganda and advertising. Agents of the Better Business Bureaus investigate advertised sales in department stores and elsewhere to check up the quality and values offered. If a store should advertise a special sale on clothing for example, in which it were said that the material from which the clothing is made is wool and that the price represents a reduction of 25 per cent and upon investigation the agent should find that the material was only partly wool and did not really represent a 25 per cent saving, the store would be called upon to reimburse its customers or be exposed and have its advertising refused by the better newspapers. "Let the buyer beware" no longer governs merchandising transactions and it is well for the pharmacist to realize this and to make sure that whenever he offers anything at a reduced price that it is really something of value and that the reduction is bona fide. It is good advertising to occasionally run a sale at which things are offered at less than the usual prices, as this provides an opportunity to dispose of shop worn and out-dated merchandise or to dispose of a large quantity of some item in a short space of time. It is essential in running such special sales to have a time limit fixed and to resume sales of the special items at the regular prices as soon as the advertised period of the sale has expired.

In line with these special sales there has come into being a type of sale known as the "one cent sale". This was introduced by a chain store organization and has been taken up to some extent by other retailers. The principle of the one cent sale is to offer two packages of an article for one cent more than the regular price of one package. Naturally a marked buying advantage of this kind finds considerable favor with the public. The one cent sales are usually conducted over a period of two days and during that time business is very brisk. Those opposed to the one cent sale say that it injures the buying public by loading them up with unnecessary quantities of merchandise. It injures the drug business in general by concentrating business into a short period of time and producing a corresponding dull period following the sale. It also is said to create a wrong public impression of the actual value of the merchandise offered, the reaction being that if the retailer can sell two of any article for the price of one, he must make an enormous profit when only one item is sold at its regular price. It is said to injure the seller because it raises a doubt in the mind of the buyer as to the legitimacy of his general merchandising methods. In favor of the one cent sale it is said many new customers are brought to the store. The head of a chain of stores has stated that a careful count and analysis shows only about 40 per cent of the items disposed of in one of these sales are bought by regular customers, the remaining 60 per cent being sold to the customers of competitors, thus drawing the latter away from their original buying centers to the new store. The one cent sale is said to make people buy when under ordinary conditions they would not be in the market for anything. It is believed to be good advertising, because it enables the pharmacist to get two pieces of his controlled merchandise into the hands of customers in place of one, thus insuring continuous allegiance to that product. It gives the customer the impression that the retailer is doing something for him.

In addition to bringing new customers to the store, the advertising, which the one cent sale makes possible for the several weeks before it is actually conducted, is of lasting benefit. There are so many ordinary sales these days and so many pharmacies advertising service and quality that one has to do some-

thing startling in order to attract more than passing attention. The one cent sale is believed to offer an opportunity of that sort. It is talked about both before and after and there is no question but that it brings people from a very large radius to the store. As has been stated, the one cent sales were inaugurated by a chain store organization and of course special controlled merchandise is sold to the units of this chain at special prices so as to assist in making the sale worth while. Outside of what is accomplished by these sales in actual profit, increased business, and the attraction of new customers, there is, of course, the value of acquainting the public with a line of products that is controlled by the chain of stores running the sales. When people have two packages of an article on hand they will certainly use them, and, having become accustomed to it to that extent, they will probably continue to use it and must naturally go to the store where the product is sold. As the line is controlled it can, of course, be obtained only in the stores of the particular chain.

Sales Management—When a store is well departmentized and certain individuals are placed in charge of separate departments it pays to establish a sales quota for each department and to make an effort to have the head of the department meet that quota or exceed it. A salesman or group of salesmen will always work better when they have a definite objective before them and of course the quota must be large enough to require an effort to meet it and yet not too large to make it impossible for them to meet it. A bonus can be based on whether the quota is reached or exceeded, or, commissions can be so arranged as to start after the quota has been passed.

Sales people should be trained never to lose an opportunity to sell as much of the store's wares as possible to any given customer. Everyone entering the store is a potential buyer of more than what he came in for. Attractive displays, a short but convincing talk, or, a suggestion here and there, will do much to increase the day's receipts. *Companion sales* are insisted upon in certain classes of stores and while it is never good policy to insist on selling too much there certainly is no objection to suggesting to the buyer of a tooth brush that he might also need tooth paste or powder, and to the buyer of soap that he might need a wash rag, or to the buyer of iodine that he might need some absorbent cotton or gauze, and so on.

If the average sale of a small store is thirty cents per customer and there are 200 customers during the day it means a day's business of $60.00. If each sale is increased only ten cents per customer it would mean a day's business of $80.00 and would probably spell the difference between prosperity and "poor business" with the average pharmacist. The time to think about increasing the average sale to the individual customer is when the individual is in the store. Once he is gone the opportunity to increase the day's receipts is reduced by just that much. Pharmacists often complain that when they take a day off and hire a relief clerk in their places receipts fall off considerably. Assuming that the relief clerk is honest there is a natural reason for the falling off. The pharmacist knows his trade and just what he can sell to each individual. He endeavors at all times to increase each sale, whereas the relief clerk is not known to the customers nor does he know them well enough to overcome a natural timidity with strangers. He is therefore more apt to simply supply what is wanted without going to the trouble of making further suggestions.

It is necessary in selling to know something about the manner in which people react to various ideas advanced by the salesman. All that has been said under advertising as to appeals to the senses or emotions, etc., is applicable here. The salesman must know how to exercise tact in all situations. Tact has been facetiously defined as "the unsaid portion of what one thinks". It

involves adjusting one's self to the customer's circumstances, to his particular intelligence, and to his environment in making the proper suggestion that will lead to increased sales. Customers range from very rich to very poor, from very old to very young, from ignorant to highly intelligent, from very active to very indolent, from ultra-careful to indifferent, and in between these extremes, there is, of course, a large group with varying degrees of carefulness and indifference, activity and indolence, ignorance and intelligence, age, and financial conditions.

Disputing with the customer is considered very bad form even though the customer may be wrong in his convictions. This does not mean that the salesman should lose his self-respect and not insist on the truth but it should be done in such a quiet way as to indicate that there are two sides to the question and that even though the customer seems to be on the other side from that taken by the salesman, there is no hard feeling over the matter but just a friendly and natural difference. Some stores work on the basis that the customer is always right, believing it to be better from a business standpoint not to argue about anything but to always satisfy the customer.

Various authors of books on salesmanship and students of the subject, have analyzed the steps taken in making a sale. Upon analysis a sale may be divided into four distinct steps: 1. The pre-approach; 2. The approach; 3. The demonstration, and 4. The close of the sale. On the part of the customer, the sale is divided into five steps, which are first, attracting attention; second, arousing interest; third, converting general interest into self-interest; fourth, creating the desire or wish to possess, and fifth, acquiring the article. Anyone who has failed in a sales effort can recall the various steps and determine just at which point the buyer lost interest. A search for the reason is thus simplified and once this is determined, the subsequent sales effort can be designed so as to avoid the error of the first effort.

Buyers may be classified as refined, sociable, argumentative, cautious, conceited, conservative, deceitful, tricky, intellectual, religious, overbearing selfish, and pessimistic. Each particular type must be met in a certain manner calculated to impress them. It is a common saying that the salesman who knows how to please a crank can please anyone, and, there are, of course, distinct appeals which work best with each one of the class of buyers enumerated. To master these is the work of many years. In fact salesmanship involves continuous study of types and situations. Deliberate planning and constant attention to details will solve the most knotty sales problem.

Deliveries and Sales Service—A delivery service of some kind is necessary in connection with any retail pharmacy. This may range from a mere errand boy service to regular automobile delivery. If a large delivery business is a natural consequence of the location of the pharmacy and the kind of business it enjoys, provisions must be made to maintain it adequately. It should be prompt enough to be worth talking about as a special service feature in connection with prescription business and yet it must not run up costs to such an extent as to make it prohibitive.

The Telephone—The telephone is a great asset to any retail business and many pharmacists have built up a good trade with families far away from their store by giving prompt, courteous and efficient attention to telephone calls and orders. Telephone customers should not be kept waiting for an answer to their "ring" or to their inquiries. A cheerful voice over the wire makes friends for the store. The speaker should imagine that the customer is before him and never venture to say anything over the telephone which would not be said to the face of the customer. A record of telephone orders should be made

immediately after they are received. Nothing should be left to memory. Convenient blank memorandum forms, close to the telephone instrument, should be provided. It is well to instruct every clerk who answers the telephone to give the name of the pharmacy rather than the usual greeting of "hello".

Items not in Stock—If a customer calls for an item that is not in stock and is either new or not generally carried, it is good business to offer to order it. In the event that the offer is accepted all possible information about the product should be obtained from the customer and information as to the customer's residence should also be secured so that he may be notified when the article arrives. An excellent blank form for this purpose is used in Petty's Pharmacy, Newark, N. J., and is reprinted here:

Selling by Suggestion—In addition to making sales by personal contact with customers, the pharmacy which is well located, well advertised and which has attractive window and counter displays will enjoy considerable sales volume resulting from the impersonal contact of the customer with the store. A store can be so arranged that suggestive salesmanship is stimulated to the highest degree. Stock can be so arranged that anyone coming inside the door to wait for a street car or consult a directory or for any other purpose will find some attention-compelling features which will lead up to a sale. Good orderly display of merchandise will accomplish this end. For instance, all preparations which relate to the treatment of the teeth may be attractively grouped so that when a customer buys a tooth brush it will be possible for the clerk to ask quite naturally: "Have you ever tried this mouth wash which we are specially recommending?" or a tooth paste of exceptional merit may be referred to, etc. Other allied toilet articles or general merchandise which lend themselves to suggestive salesmanship should be grouped. Suggestive salesmanship involves good display of merchandise with prices in plain view; convenient arrangement of cases and other fixtures so as to group the things wanted quickly where they are readily accessible; judicious use of counter signs telling a complete story briefly and attractively.

SHOW CARDS AND SHOW CARD WRITING

Attractive show cards can accomplish much in the way of suggestive selling. In the average pharmacy, so many goods are on display that it is difficult to make a show card stand out. It must either bear a striking illustration or a catchy phrase. Sometimes the size of the card or the distinctive lettering on it creates the desired effect. The preparation of show cards is not as difficult as might be imagined by those who have had little or no experience in their preparation. However, as is the case in all other arts, perfection is only obtained by constant practice. The quality of the materials used has considerable bearing on the final product. There are show card writers who are sufficiently artistic to get good results even with poor materials but the average amateur in this work needs all of the advantages which good materials provide. If the

FIG. 468

Illustrations of brush lettering

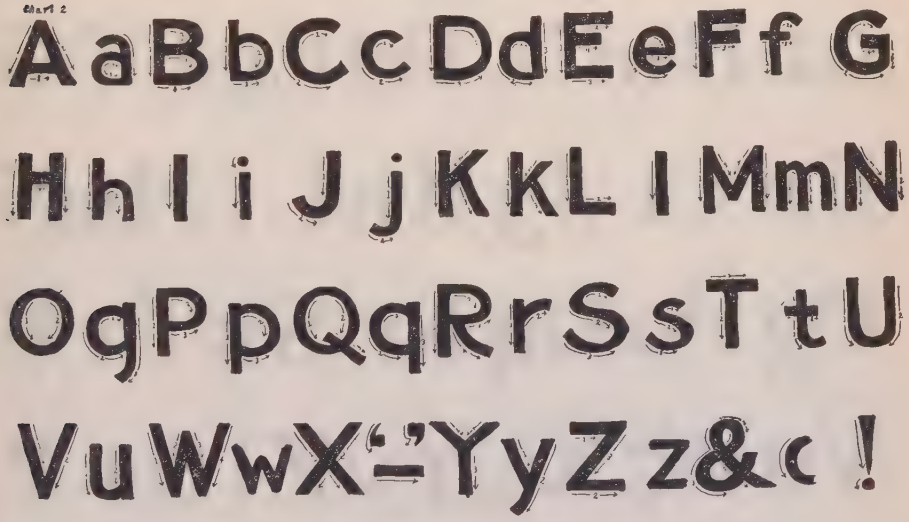
pharmacist has to do his own show card writing or if one of his clerks is delegated to do it, the materials necessary are brushes, lettering pens, paints and inks, cardboard of various colors, and perhaps some discarded advertising material which can be used in making illustrations by cutting to the outline of the picture and pasting it on the show card.

Brush Lettering—When using brushes to make signs it is necessary to obtain special brushes that have been made for lettering. The ordinary soft camel's hair brush is not satisfactory. "Red Sable Show Card Lettering Brushes" are very satisfactory. They may be obtained either flat or round. For the beginner the flat brush is best. These brushes range in width from $\frac{1}{8}$ to $1\frac{1}{4}$ inches and are sold according to width. The $\frac{1}{4}$ inch, $\frac{3}{8}$ inch, and $\frac{1}{2}$ inch brushes are probably sufficient for ordinary work. The necessary supplies for this work can be obtained at art or paint shops. Brushes should be washed out thoroughly in water after using, and the surplus moisture should then be squeezed out by gentle pressure, sliding the thumb and forefinger toward the brush point. A brush should not be allowed to dry out without having the color

washed out of it, nor should it be allowed to stand upright leaning on the hairs. When brushes are properly cared for they will last a long time and, as a matter of fact, they improve with constant use. If paint has been permitted to dry in the brush, the hairs should not be bent as they may have become brittle and will break off; the soiled brush should be placed in water and permitted to soften, after which it can be washed out again. When not in use, brushes should be kept lying flat or resting on the handle in a jar with the brush end upward. If a brush is permitted to rest on the hairs, the latter will curl and the brush will be unfit for further use.

Pen Lettering—Pens for show card work are of special construction and are obtainable in many sizes. The R. Esterbrook and Company's drawing and lettering pens, numbered 1 to 4, will meet the needs of the ordinary show card work. Pen holders, water, white and colored chalk, a hand ruler, a piece of art

FIG. 469



Single stroke, stump letters

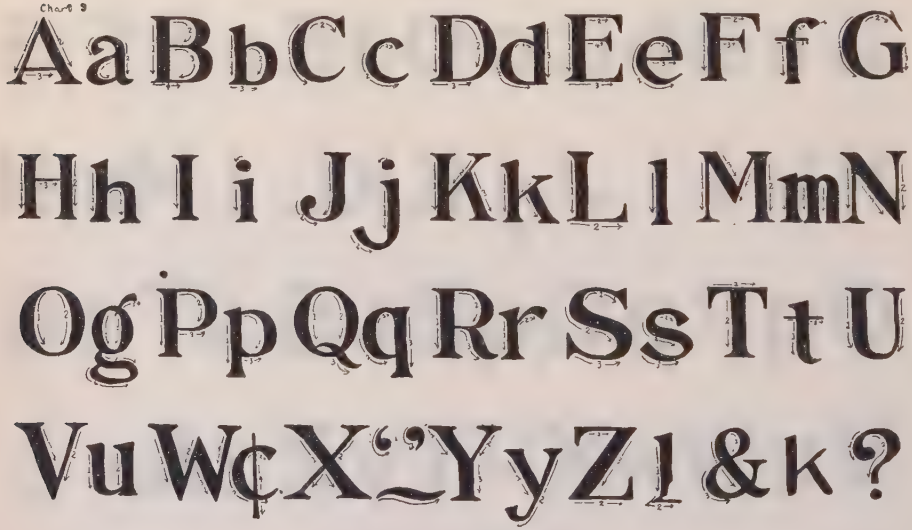
gum, sticks of charcoal, some thumb tacks, cardboard, Carter's or other water paints, and a piece of chamois skin, will complete the outfit. Oil paints should not be used for show card work and the brushes should not be permitted to come in contact with such paints or with any fat or grease. For show card work, paints that are especially adapted should be used. They may be obtained in all colors and are supplied in small glass jars at paint and art shops.

White cardboard is the best for show cards. It can be purchased in various thicknesses. The thinest cardboard, satisfactory for show card purposes, is four ply, but this is really too thin to be durable. Six ply is a more satisfactory cardboard to use and ten ply is as good as is necessary. Of course the cost increases with the thickness of the cardboard.

A rough layout can be penciled on the card and erased with the art gum after the lettering is completed and dry. One of the objects to be accomplished by a beginner in this work is to train the eye as well as the hand. It will be found that constant practice will make it almost unnecessary to have more than a very sketchy outline of a card in order to produce well-proportioned

results. In the accompanying illustrations are shown letters made with a brush and with a lettering pen. Fig. 468 gives the brush strokes involved in ordinary lettering. The beginner can take some plain paper about 12 x 18 inches and fasten it on a flat surface over a smooth table top or a card about 22 x 28 inches and then lay the sheet out into 1¼ inch squares. The brush is dipped into the show card paint after the latter has been stirred thoroughly with a stick and the brush is then stroked on the edge of a saucer until most of the paint is released. This is done several times until a fair amount of paint has been transferred to the saucer. The brush is now dipped into clean water and the stroking process on the saucer repeated until the paint has been reduced to the proper consistency. The brush is now carefully stroked to and fro through the paint and water until they are well mixed and the brush is thoroughly saturated with paint. The brush should not be twisted in the

FIG. 470

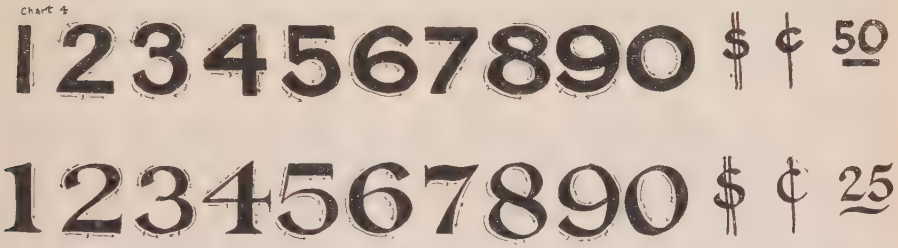


The Roman alphabet

paint but pulled through on its flat sides. The flat sides are then wiped on the edge of the saucer and the brush is wriggled on a piece of paper until it assumes a flat chisel shape. It is now ready for lettering. The brush should be held gently but firmly between the thumb and forefinger. The other part of the hand is allowed to rest on the table. The beginner should start in boldly to make the strokes outlined in Fig. 468. It is not advisable to be overcareful or to watch detail at this point. The important thing is to gain confidence and the ability to make the strokes rapidly and evenly. It is well to follow the directions of the strokes as indicated in the illustration. The letter A consists of thin lines whereas the letter B is made up of thick lines. This requires manipulation of the brush so that the "chisel end" is perpendicular to the body when making the letters A and B. In making letter B, the position of the "chisel end" of the brush in relation to the body is not changed but the handle should point to the right. The letter B is made by dragging the brush to the right. It should be remembered that the hairs of the brush are always

to be dragged and never pushed. The handle of the brush should always point in the direction in which the stroke is being made. Vertical and diagonal strokes, both straight and curved, are made from top downward. Horizontal

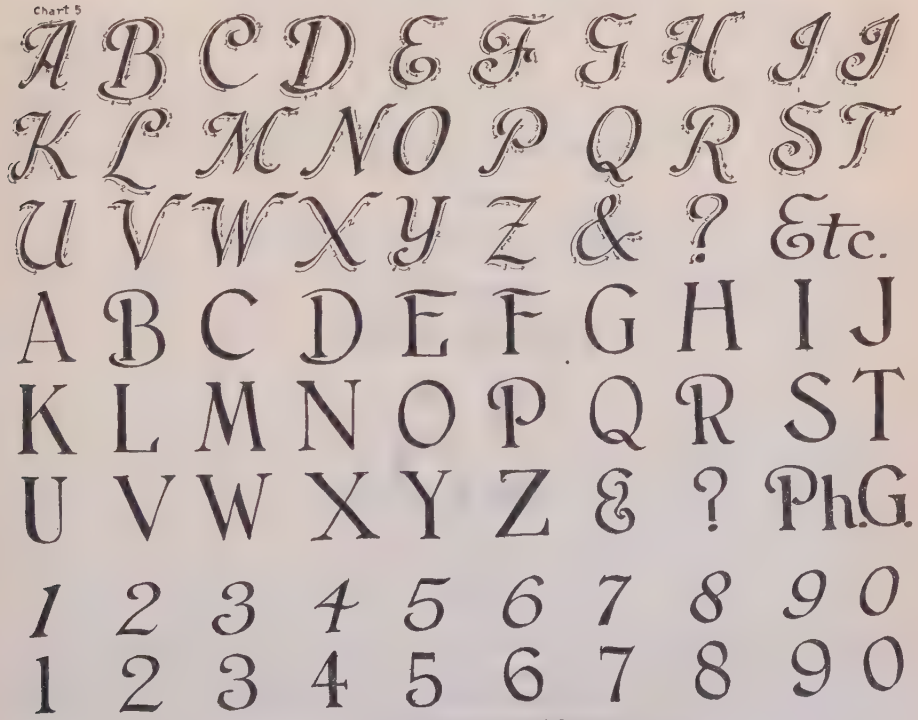
FIG. 471



Various styles of figures

strokes, both straight and curved, are made from left to right. The brush should be saturated with paint all of the time. It is impossible to work properly with the tip of the brush alone. There should be pressure on the brush at the

FIG. 472

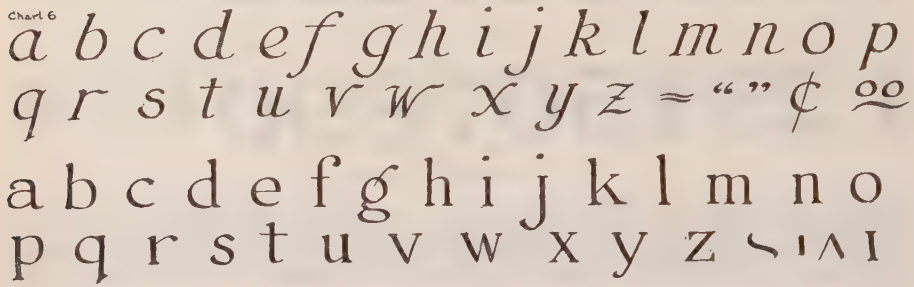


Various styles of letters and figures

start of the stroke and as the end is neared, the pressure is released, first slowly and then suddenly. It will be necessary occasionally to straighten out the hairs of the brush by stroking it on a piece of paper.

The letters C and D are made by holding the brush at right angles to the position required in making the letters A and B. Letters E and F are similar to letters A and B, the difference being that they are oblique. The letters from G to N present little difficulty after letters A to F have been mastered. Letter O introduces curves which may be found somewhat difficult at the start. The brush should be held in the same position as when making letters C and D,

FIG. 473



Illustrations of pen lettering

pressing a little at the start and increasing the pressure as the curve is rounded, and releasing the pressure at the end. The letter P involves the same technic only in the opposite direction. Letters Q and R are combinations of O and P, the only difficulty here is to join the component parts properly. This requires some practice. The so-called single stroke, stump letter is outlined in chart Fig. 469. This is a very satisfactory and legible letter, one which even an inex-

FIG. 474

Typical price card

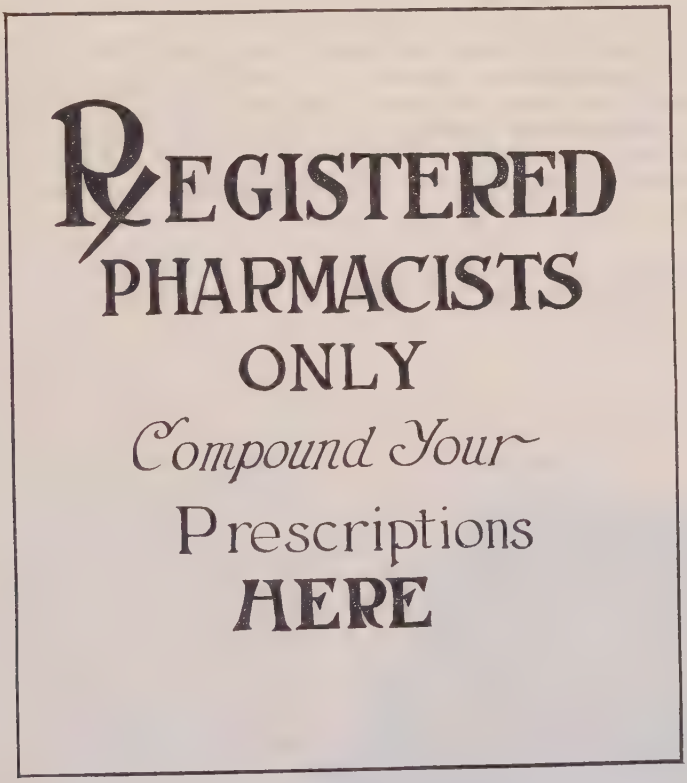
perienced show card writer can use without much difficulty. After the main strokes indicated by the arrows have been made, the ends of the letters can be evened up by drawing the flattened brush across them. Lower case or small letters are about two-thirds the size of capitals.

In Fig. 470 a Roman alphabet is presented with the various strokes indicated. In order to make the spurs on these letters, the brush is first swung to the right or left and lifted gently but suddenly and then the same stroke is repeated, swinging the brush to the opposite side and again lifting it gently but

suddenly. A hair line is then drawn with the "chisel end" of the brush to complete the outline of the spur and any white space remaining is filled in. It is essential to put the spur on the letter while making the regular strokes. It should not be put on after the outline of the letter has been completed. Figs. 471 and 472 represent other styles of letters.

Pen Lettering—Fig. 473 represents letters made by the use of a lettering pen instead of a brush. The beginner will find the lettering pen much more satisfactory to use than a brush, his hand will be steadier and there will be

FIG. 475



Typical show card

less difficulty in following the lines as indicated by the arrows. The method of working is exactly the same as described in the case of the brush. The reason why the brush is preferred for some signs is because it makes a heavier letter and is, of course, much more satisfactory for very large work. The pen does not hold enough ink or paint to make its use satisfactory in large or heavy letters. The same colored paints that are used for brush lettering can be used for pen lettering but it must be thinned until it flows readily by adding water. For black lettering with a pen, it is best to use a preparation known as "Letterine" or "Higgins' India ink".

The Layout of the Card—Do not crowd the letters on a show card. The total margin should always equal the width of the lettered section to get the

best results, that is, if the card is 12 by 14 inches, the margins at the top and bottom should each be 3½ inches (total margins equal to one-half the length) and the side margins should be 3 inches each. Fasten the card to the table so that the edge of the card is along the table edge, and holding the sharpened piece of charcoal firmly against the end of the ruler, grasp the ruler firmly with the other hand, extending the index finger, and draw the desired guide line with the charcoal, guiding it and keeping it straight by running the extended index finger along the table edge. The line may be placed in any position on the card by grasping the ruler in different positions. Of course the line is always drawn parallel to the table edge. It is desirable to draw these charcoal guide lines for margins and also to indicate the height of letters. They may readily be erased after the paint is dry, by the use of the chamois skin.

Figs. 474 and 475 illustrate the possibilities of even black and white cards and the addition of color on the border or the use of an appropriate and attractive picture in one corner, will notably increase its value. Attention might be called to the advantage of using a safety razor blade, preferably one with a single knife edge, for cutting out an illustration. When pictures are pasted on the card they should be covered with a piece of clean paper and all wrinkle rubbed out.

CHAPTER LXXXIV

ACCOUNTING AND THE NECESSITY FOR PROPER ACCOUNTS

It should not be necessary to urge the keeping of accounts upon those who entrust their prosperity to the exigencies of business. Accounts should mean as much in the control and direction of business as a chart and compass to the captain of an ocean liner.

When business is small, the necessity for records of accounts is not so apparent. The captain of a ferryboat rarely needs his compass, yet he has it and must know how to use it if the emergency should arise. Facts show that a small and unprofitable business and a failure to keep and appreciate the importance of proper accounts so frequently parallel each other, that one of the laws of success would seem to read, "Keep proper accounts".

Of course requirements vary greatly, but the safe guidance of any business is dependent upon financial records which are only obtainable from "books of accounts".

Bookkeeping enters two clearly defined divisions of a business but the final record in both fields must become a part of the complete statement to show the proprietor the degree of success attained.

One division of accounts referred to above covers the basic financial transactions of every business such as capital invested, purchases of merchandise, the expense of conducting business, and a record of sales including a regular statement showing their relation to profit.

The second kind of accounts is only required when credit is allowed to customers. They consist of a detailed record of purchases on credit, the crediting of payments "on account", and a frequent summary, in detail or total, showing accounts unpaid. Such a statement is usually accompanied or followed by a special effort to make collections.

Fig. 476

Cash register

If a strictly "cash" business can be conducted, this second class of accounts is eliminated. In many small businesses a record of the credit accounts is the only systematic accounting done. The immediate need forces this accounting upon the business and the proprietor will take the time for the benefit of his customer, primarily, but fails to find time for the first class of records which are chiefly for his own benefit.

Bookkeeping, which provides a systematic record for the proprietor of the status of the business, will first be considered.

Standard systems, either *single entry* or *double entry*, are taught in practically every high school and business college, therefore, no attempt will be made here to fully explain these generally known systems.

A brief outline of typical business transactions will, however, be carried through a set of standard bookkeeping records to enable the student quickly to

review the training already received in regular bookkeeping (see page 1395). These records require the cashbook, a daybook, and a ledger; also subsidiary records such as are kept in the check book and bank book.

The adaptation of special systems to a retail drug store has greatly simplified the securing of these very important records.

Daybook or blotter

One such system, devised by E. Fullerton Cook, with the coöperation of Harold J. La Wall, an expert accountant, is also illustrated (see page 1403). This system has been developed through direct contact with the needs of retail drug stores and has been in operation in a number of drug stores for the last ten years, with much satisfaction to the proprietors. Columnar records are the basis of the system. It has the advantage of greatly reducing the writing needed for records, but its greatest value is in placing before the proprietor all of the vital figures in his business without the necessity of a formal closing of the books and the preparation of the statement of losses and gains. Those who have had experience know that such a statement is not easily prepared from an old-fashioned set of books and consequently is frequently postponed until the facts are too late for service.

Valuable bookkeeping aids are given by the use of "cash registers". The readings taken from these machines at the close of each day's business, make it possible for the proprietor to readily obtain facts concerning sales and petty expenses, that they may be available for subsequent analysis. In the case of one successful retail druggist his cash register readings twice a day tell him what clerks are on the job; what clerks are falling down; what department is weak; and even what is wrong with his window displays. They also give him accurate comparisons that are valuable. A National Cash Register of the counter cabinet type with four cash drawers is shown in Fig. 476.

Accounts Necessitated by Credit Customers

When credit has been granted, and customers are buying drugs and merchandise on account, it is of vital importance that the proprietor keep an accurate record of every such sale. The importance of this cannot be overestimated as the facts will show that few retail businesses exceed a 10 per cent net profit at the close of the year, and the failure to charge a dollar sale would therefore, necessitate $10.00 worth of additional sales to overcome this single loss. The first step, however, is to provide a proper book or books in which to make the original entry when the sale is completed. The smaller stores have been accustomed for years to use a daybook or "blotter" in which the details of the sale are entered when the transaction is completed. This detail

includes the name of the customer and this is followed by the itemized sales (see Fig. 477). This is termed the "book of original entry", and whatever form it may assume it occupies the same position before the law, *i. e.*, it constitutes legal evidence of the authenticity of the sale, should that be questioned.

Charge slip

Instead of the daybook, it is customary in many stores to use the small "charge" and "credit" slips (see Figs. 478 and 479). The slip, after writing up the sale, is rung up on the register, under the "charge" key, and deposited in the drawer.

FIG. 479

Bill of last month	4	80

Credit slip

In larger stores, a duplicate or triplicate system of sales slips is sometimes used, the original usually going to the customer direct, the second going to the accounting department, and the third remaining in the sales book as a check against the original. Great varieties of such forms are now used in department stores, all sales, whether cash or credit, being so recorded.

When the "original entry" has been made, the details of the sale must be

assembled in a book called the "ledger". Original entries are made in the daybook chronologically, but in the ledger they are assembled systematically under the names of the customers so that the status of any account may be known in a few moments.

When the credit period is past or on the first of each month, a bill is sent to the customer setting forth in detail the items which have been charged and the prices. It is desirable that this statement should be issued promptly, business custom having established the first of the month as the day. When bills are not received on the first of the month, customers frequently set them aside until the next month and from the viewpoint of the proprietor it is essential that payment should be made as promptly as possible. A "billing ledger" with the aid of which the handling of charge accounts is greatly simplified

is illustrated and explained on page 1403. The use of this form of ledger eliminates the necessity of keeping any other form of ledger for credit customers.

When an account is opened with a new customer, it is essential that evidence should be in the hands of the owner of the store, indicating the financial standing of the person applying for credit. When the organization is large, the establishing of credit is placed in the hands of an individual or department, having facilities for determining financial rating.

In a small business it is also of importance that the proprietor or whoever may have charge of the accounts, have evidence of the financial responsibility of the customer. Frequently this is known through personal acquaintanceship. In many communities, the retail merchants conduct a credit association and willingly supply information concerning the financial reliability of all persons living in the neighborhood.

It is of great help to use a printed form, as it impresses the customer with the business-like methods under which the store is conducted and furthermore commits the customer to a definite agreement. Such a form is printed above (Fig. 480). It will be noticed that the form specifies those who may be permitted to charge on the account. This is desirable information.

If the bill is not paid within the month, it is customary to send a *"statement"* which simply gives the total due on a previous date, this oftentimes being added to the bill of the current month.

Accounts Necessary for an Intelligent Control of Business

As already explained, a business without proper financial records is like a ship without a rudder. It flounders helplessly and guesses its course of action and only too often ends as a wreck. But for the proper understanding of accounting there should be actual experience in the handling of various business transactions, entering these in the appropriate books of record and subsequently drawing conclusions concerning the business, to determine whether it has been conducted at a loss or with a profit. These records should show many other facts, such as the cause of a loss, if such occurs, and the place to apply the remedy, the amount of income tax to pay, and many other guiding facts in the success of the enterprise. These facts properly come from the actual conduct of business and such figures are offered here for illustration and practice.

An Outline of a Month of Business

Preliminary Statements—On the following pages will be found a brief outline covering typical transactions in a drug store. These have been especially selected for instruction in bookkeeping. The business under consideration was started almost two years prior to the date of the detailed transactions but all essential factors, including such items as capital invested, inventories, etc., are given in a preliminary statement.

The business transactions are presented in this manner that they may be used in bookkeeping classes or in a study of accounting. The arrangement requires the closing of the books at the end of a second year of business. This makes necessary the preparation of all closing records and their analysis in the interest of efficient business control.

Following the statement of preliminary facts concerning the business and a skeleton outline of the routine transactions of a month of business (December), there will be found on pages 1402 to 1410 a brief review of *single entry* and of *double entry bookkeeping*, in which these transactions are entered in the several books which are illustrated. The necessary analysis statements are also given.

Following this, on pages 1411 to 1421, these same transactions have been entered upon columnar sheets, with appropriate explanations, for the purpose of calling attention to a system of bookkeeping which is much more practicable for the retail drug store and which offers a valuable business guide for the retailer with a minimum amount of labor.

In working out this bookkeeping problem, the name of the one doing the bookkeeping, or a fictitious name, if that is preferred, should be entered as the proprietor. If your own name is used, it gives a suggestion of reality and adds a personal interest to the work.

All transactions are numbered for ready reference in teaching.

Details of the Business—

1. Use your own name throughout these accounts, and at the beginning adopt a signature which will be uniform for all business papers.

2. That these transactions may seem more personal and real, you are asked to assume that you have been in business at 63rd and Clinton Streets, for almost two years, December 31 next, closing the second year.

3. When you began business you had saved $1630.00, and $1500.00 of this was used as a part of the first cash payment on this store which was bought from C. L. Martin. The balance, $130.00, remains on deposit in the Western Savings Fund Society.

4. You also arranged a loan of $5000.00 from your father, and secured this by means of promissory notes of $500.00 each, made payable to your father with interest in advance, at 5 per cent. The notes are for one year, two years, three years, and up to ten years, respectively.

5. In purchasing the drug store at 63rd and Clinton Streets, almost two years ago, from C. L. Martin, the value was estimated at $15,700.00, divided as follows:

Stock of general drugs and sundry merchandise	$7,163.70
Soda supplies	108.20
Candy stock	82.50
Cigar stock	145.60
General fixtures	4,400.00
Soda fountain	1,800.00
Transfer of lease and goodwill	2,000.00
	$15,700.00

6. The terms of sale at that time were as follows: A cash payment of $5000.00, and the balance, $10,700.00, in ten annual payments of $1070.00 each. Ten judgment notes, with interest in advance at six per cent, each for $1070.00, were given Mr. Martin as security. One of these notes falls due each year until the tenth is paid.

7. At the beginning of the first year, the following payments were made:

Interest in advance on the notes given your father ($5000.00 at 5 per cent)	$250.00
Interest in advance on Martin's notes ($10,700.00 at 6 per cent)	642.00

8. At the close of the first year the following payments were made:

First payment on principal (your father's note)	$500.00
First payment on principal (Martin's note)	1070.00

9. At the beginning of the second, or current year, the following was paid:

Interest on your father's note ($4500 at 5 per cent)	$225.00
Interest on Martin's notes ($9630 at 6 per cent)	577.80
	$802.80

10. *A Bank Account*—A bank account is opened with the Training National Bank, an introduction to the cashier being secured through Mr. Martin. Your signature was registered and the necessary books, *viz.*, bank book and check book procured.

11. *The Lease*—The building in which the store is located is owned by H. H. Wood, of ———. The lease was originally drawn for ten years and had run for two years when you took over the business. It is transferred to you through the consent of Mr. Wood, and a new lease drawn for the

unexpired term. This lease sets forth the following facts concerning your position as tenant:

That C. L. Martin, being tenant under lease given by H. H. Wood, of ———, hereinafter called the lessor, doth hereby underlet unto (————) of the City of ———, hereinafter called the lessee, the first floor storeroom, rear yard, cellar and third floor front bedroom situated on the premises known as 6300 Clinton Street, in the City of ———, for the term of eight years from the first day of January A. D. 19—, at a yearly rate of fourteen hundred and forty and $\frac{x}{100}$ dollars, lawful money, payable in monthly installments on the first day of each and every month. The first payment to be made on the first day of January A. D. 19—.

The lessor hereby agrees to keep and maintain the leased premises in good condition and repair, and at all reasonable times to paper and paint said rooms in a manner satisfactory to the lessee.

The lessor further agrees to pay all taxes and water rent assessed on the premises or any part thereof, and to maintain a perpetual policy of fire insurance to the value of $20,000 $\frac{x}{100}$ upon the same.

The lessee hereby agrees to occupy the storeroom contained in the premises only as a drug store; the rear yard and the cellar only for the receiving and storing of goods necessary and proper to the drug business, and the third floor room only as a private living apartment, and agrees not to underlet the same or any part thereof, or assign this lease, without the previous written consent of the lessor.

Your father agrees to be responsible for your faithful fulfillment of these contracts.

The usual agreements, covering the interests of the landlord, are also included in the lease.

12. *Fire Insurance*—You are carrying the following insurances at this time:

Fire insurance $13,000.00. The policy was paid for at the rate of forty cents for each $100.00 of insurance. The policy, No. 1,662,490, was taken out January 1, of the current year, in the Druggists' Mutual Fire Insurance Company, for one year.

The details of this policy are as follows:

On merchandise generally and bottles and packages containing the same, chiefly drugs, medicines, druggists' sundries, chemicals, cigars, tobacco, syrups and extracts, ice cream, stationery for sale, fancy and toilet articles and supplies, their own, held in trust or on consignment, or for which the assured may be legally liable in the event of loss or damage by fire, or sold but not removed. ($6000.00.)

On all other contents appertaining to the business not mentioned above, chiefly store and office fixtures and furnishings either useful or ornamental, decorations, counters, safes, partitions, cases, shelvings, racks, scales, and weights, machinery, machines, fuel, tools, implements, apparatus, utensils, bottles, jars, labels, inside and outside signs and awnings, floor coverings and mosaic flooring, electric fans, lighting apparatus, stoves, clocks, pictures, mirrors, stationery supplies for use, advertising matter, typewriting machines, cash register, soda water fountains and their appurtenances.

All while contained in or attached to the brick building, situated at 6300 Clinton Street, ———, occupied as a retail store and dwelling.

Privilege: of other insurance without notice until required; to make additions, alterations and repairs; and to keep for sale not more than five (5) gallons (in all) of gasoline, benzine or naphtha.

Lightning, Exclusion and Electric Current Clauses.

Lightning Clause—(Excluding Damage to Electric Apparatus.) This policy shall cover any direct loss or damage caused by lightning meaning thereby the commonly accepted use of the term "lightning" and in no case to include loss or damage by cyclone, tornado or windstorm, not exceeding the sum insured, nor the interest of the insured in the property, and subject in all other respects to the terms and conditions of this policy. *Provided*, however, that if there shall be any other insurance on said property, this company shall be liable only pro rata whether such other insurance be against direct loss by lightning or not, and provided further that if dynamos, wiring, lamps, motors, switches, or other electrical appliances or devices are insured by this policy, this company shall not be liable for any loss or damage to such property resulting from any electrical injury or disturbance, whether from artificial or natural causes, unless fire ensues, and then for the loss by fire only.

It is understood and agreed, that this insurance does not cover and will not be liable for loss to accounts, bills, currency, deeds, evidences of debt, money, notes or securities.

ELECTRIC CURRENT CLAUSE

Permission is granted under this policy for the use of Electric Current after certificate of approval has been issued by the ——— Fire Underwriters Association and while it remains unrevoked by said Association.

Attached to Policy No. 1,662,490 of the Druggists' Mutual Fire Insurance Company of New York.

Workman's Compensation Insurance for which you pay an annual premium of $19.00. This is the minimum premium for this form of insurance, and, with the rate of 19 cents per $100.00 assigned to drug stores by the ——— Insurance Commission, covers about an annual pay roll of $10,000.00, and protects you against any compensation awarded under the law to your employees in case of accident.

Liability Insurance—You also carry liability insurance for which you have paid $13.00 on January 1 of the current year. This protects you and your registered clerks against mistakes in prescription compounding or in the dispensing of poisons, and also provides legal counsel and awarded damages, if any, from suits at law for injuries, either actual or supposed, up to an amount not exceeding $2500.00.

13. *Credit Customers*—The following customers have been allowed credit after suitable investigation of their financial standing, and accounts were opened:

1. John L. Scott, 6125 Market Street. Balance due December 1, $13.50.
2. B. C. Hastings, 6331 Chestnut St.
3. J. P. Milkins, 415 South 63rd Street.
4. Mrs. S. R. Palmer, 5840 Clinton Street. Balance due December 1, $4.80.
5. Dr. F. T. Brown, 840 South 64th St. Balance due December 1, $10.32.
6. William C. Campbell, 6360 Chestnut Street.
7. Mrs. B. C. Hall, 234 North 62nd Street.
8. Miss Mary L. Adams, 6360 Arch Street. Balance due December 1, $8.60.
9. Frank F. Mason, 6536 Market Street.
10. L. C. Beaver, 6163 Clinton Street. Balance due December 1, $6.10.
11. A. S. Wilson, 6537 Arch Street.
12. J. S. Hayes, 6620 Market Street. Balance due December 1, $10.12.

14. *Inventory*—The inventory at the beginning of the current year was as follows:

Fixtures (all but soda fountain) ($4400.00 less 5 per cent depreciation)	$4,180.00
Soda fountain ($1800.00 less 10 per cent depreciation)	1,620.00
Goodwill ($2000.00 less 20 per cent charged off)	1,600.00
General drugs and sundries	8,133.30
Soda supplies	124.50
Candy stock	151.20
Cigar stock	91.00
Coal	30.00
Office supplies	24.80
	$15,954.80

15. *Miscellaneous Business Facts*—The total sales of the previous year were $34,048.60.

16. Credit sales amounting to $87.50 remain unpaid at the beginning of the current year. (Note—Only a few credit customers are listed to lessen the amount of work required. The same principles apply to any number of customers.)

17. The cash on hand at the beginning of the current year was $2371.68.

18. The capital invested in the business by the proprietor at the beginning of the current year was found to be $3211.78.

19. On the beginning of the current year, January 1, invoices for supplies purchased remained unpaid as follows:

Prescriptions, mdse	$890.72
Soda	8.46
Candy	140.75
Cigars	32.27
	$1,072.20

20. Unpaid invoices as of December 1 Current year

		Less 2 per cent discount
Smith Baker and Co., mdse	$960.35	$941.14
Whitney Chemical Co., Chemicals	122.60	120.15
Boyd Whitney Co., Candy	152.70	149.65
Knight Cigar Co., Cigars	80.60	78.99
		$1,289.93

21. **Brief Outline of Detailed Business Transactions**

Monday, December 1, 19—

1. Cash on hand:

In store, for change	$50.00
In bank, subject to check	$3,238.60

2. Pay H. H. Wood, by check, for the December rent, $120.00.

3. Sold John L. Scott, on account, 6125 Market St., 1 lb. sugar of milk, 65 cts., 1 pt. olive oil, $1.25.

4. Cash sales for the day: mdse., $84.40; soda, $18.25; candy, $11.50; cigars, $7.30.

5. Pay Mary Wright for cleaning, $3.50; charge to miscellaneous expenses.

Wednesday, December 3

6. Sold B. C. Hastings, on account, 6331 Chestnut St.
℞ 38362, $1.25 1 pt. Lime Water and bottle, 25 cts.
1 pt. Ext. Witch Hazel, 35 cts.

7. Pay $2.00 for advertising in a programme of St. John's Church, charge to advertising.

8. Cash sales, Dec. 2 and 3: mdse., $153.84; soda, $35.15; candy, $15.30; cigars, $12.40.

(NOTE—The sales of several days are combined to lessen the number of entries. If desired the amounts may be proportionally divided to show daily sales and be recorded as such.)

Saturday, December 6

9. Sold Mrs. S. R. Palmer, on account, 5840 Clinton St. (Balance now due on her account, $4.80):
6 (1 gal.) bottles Crystal Spring Water at 50 cents a bottle (refund 25 cts. per bottle when returned); 1 bottle extract of vanilla, 25 cts.

10. Paid from cash $5.00 for stamps for sending circulars to customers and deposited in the bank all cash in the store except $50.00 for change.

11. Pay the following salaries for the week:

Your own salary, by check	$45.00
James T. Harris, registered clerk by check	45.00
Miss Thompson, by check	15.00
William Smith, cash	15.00

12. Cash sales, Dec. 4, 5, 6: mdse., $243.13; soda, $72.20; candy, $38.15; cigars, $28.50.

Wednesday, December 10

13. Bought a broom for 85 cts., miscellaneous expenses; paid cash.

14. Bought 100 lbs. sugar for soda fountain at 8 cts.; paid cash.

15. Dr. F. T. Brown paid his bill due Dec. 1.

16. Bought 5 tons of stove coal, at $16.25 a ton; paid by check.

17. Paid gas bill, by check, $3.75.

18. Paid electric light bill, by check, $14.65.

19. Cash sales, Dec. 7, 8, 9, 10: mdse., $198.15; soda, $51.90; candy, $21.80; cigars, $17.60.

20. Paid Smith Baker Company, bill of Dec. 1, $960.35, for general mdse., deducting 2 per cent.

21. Paid bill of Whitney Chemical Company, $122.60, for chemical supplies, less 2 per cent.

22. Mrs. S. R. Palmer paid her bill of last month.

23. Paid bill of Boyd, Whitney Company, for candy, $152.70; less 2 per cent.

24. Paid bill of Knight Cigar Company, bill $80.60. less 2 per cent.

Saturday, December 13

25. Sold John L. Scott, on account, ¼ lb. absorbent cotton, 25 cts.
Hot-water bottle, $2.25.
He paid his bill of last month.

26. Cash sales, Dec. 11, 12, 13: mdse., $272.12; soda, $79.15; candy, $35.70; cigars, $31.10. Deposited in the bank all cash except $50.00 for change.

27. Paid the following salaries for the week:

Your own salary, by check	$45.00
James T. Harris, by check	45.00
Miss Thompson, by check	15.00
William Smith, cash,	15.00

Thursday, December 18

28. Sold B. C. Hastings, on account, R 38715, 75 cts.; R 38716, $1.35; 1 perfume lamp, $3.75.

29. Bought decorative material, $5.20.

30. Bought lemons and oranges for soda fountain, cash, $3.60.

Saturday, December 20

31. Bought of Smith Baker and Company, mdse., payable before January 10. Net $412.24.

32. Cash sales for week, Dec. 14 to 20: mdse., $721.41; soda, $127.50; candy, $92.30; cigars, $143.05. Deposited in the bank all cash except $50.00 for change

33. Bought of Knight Cigar Company, cigars, payable before January 10. Net $118.21.

34. Paid the following salaries for the week:

Your own salary	$45.00
James T. Harris	45.00
Miss Thompson	15.00
William Smith	15.00
Extra help, 6 days, at $4.00	24.00

35. Miscellaneous expenses: Carfare, $1.20; messenger service, 75 cts.; special circulars, $10.30; price cards and window cards $16.00.

Saturday, December 27

36. Paid the following salaries for the week:

Your own salary	$45.00
James T. Harris	45.00
Miss Thompson	15.00
William Smith	15.00
Extra help, 6 days, at $4.00	24.00

Deposited in the bank all cash except $50.00 for change.

Wednesday, December 31

37. Cash sales, Dec. 21 to 31: mdse., $1546.75; soda, $127.80; candy, $170.70; cigars, $101.25.

22. *Miscellaneous Items*:

Paid by check second payment on principal (your father's note)	$ 500.00
Paid by check second payment on principal (Martin's note)	$1,070.00

Unpaid account of J. S. Hayes, 6620 Market Street, amounting to $10.12, charged off to bad debts. It was found he left the city and could not be located.

23. *Inventory*, December 31, is as follows:

Fixtures (all but soda fountain)	
$4180 less $220 Dep., *i.e.*, 5% of orig. invest.	$3,960.00
Soda fountain	
$1620 less $180 Dep., *i.e.*, 10% of orig. invest.	1,440.00
Goodwill	
$1600 less $400 Dep., *i.e.*, 20% of orig. invest.	1,200.00
General drugs and sundries.	9,220.10
Soda supplies.	132.50
Candy stock.	141.60
Cigar stock.	105.00
Coal.	30.00
Office supplies.	24.80
	$16,254.00

Single Entry Accounting—

The Daybook—The usual form of daybook, as found in a retail drug store, consists of a book ruled as shown in Fig. 477. Into this are entered the records of credit sales. Here will be placed, under the date, the name of the customer and the itemized sale. Frequently this book is used for recording the initial payment "on account" by a credit customer. In many stores the original entry of a credit sale is made upon a small pad of paper, suitably ruled, and the individual record rung up in the cash register under the "charge" key. In some cash registers the amount is also recorded in the register on a tape, thus providing a check against the possible loss of the "charge" slip.

If "double entry" books are not employed these "original entries" of charges and also credits, when entered on the "daybook", are now "posted" in a personal ledger.

The Personal Ledger—(Single Entry). If regular double entry accounts are not being maintained, the charge accounts may be handled by "single entry". This means, of course, that when an item is debited it is posted but once in the ledger, that entry being under the name of the customer who has made the purchase. When a customer pays on the account, he in turn is credited in the ledger. This gives to the proprietor a summary in the ledger, under the name of each customer, of all purchases and sales on account, by the individual or firm involved. The monthly bills and statements are made up from this ledger record. This ledger must be properly indexed, or, if a

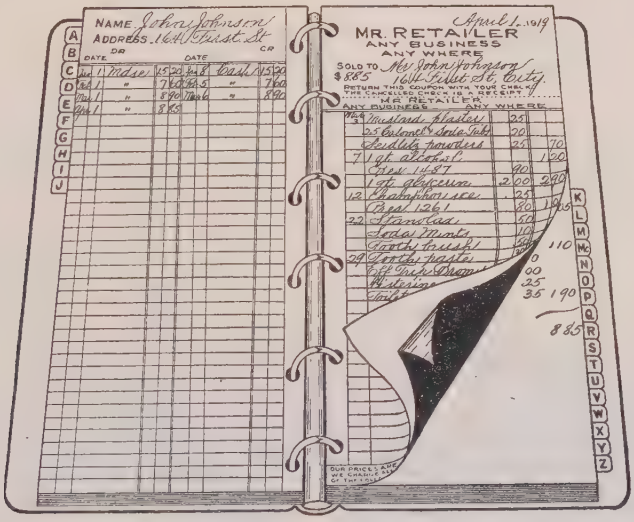
Personal ledger (single or double entry)

"loose-leaf ledger", it must be arranged in alphabetical order. Every entry in the ledger should also carry a memorandum of the page number, or the "charge" slip number, from which the original entry was taken.

The Billing Ledger—In modern systems of accounting it has become almost universally the custom to use the principle of the billing ledger for personal accounts. A typical ledger of this character, suitable for use in a retail drug store, is shown in Fig. 482. It is sold by the LaWall Systems, of Philadelphia. The many advantageous features are clearly indicated. The ledger entry is always before the proprietor, although the record need be but the total of the month's debits and credits, a single entry.

The necessity of transferring details to the ledger is made unnecessary through the use of a carbon copy duplicate, thus avoiding one complete writing of the credit sales of the month. The billhead itself carries a stub

FIG. 482



Billing ledger

at the top which, when used in a window envelope, serves as the address. This may also be torn off and returned by the customer with his check and avoids the necessity of a receipt as it states distinctly that no receipt will be returned except upon request, the canceled check being considered sufficient. At the bottom of the bill there is a polite reminder that credit is a favor and that prompt payment is expected.

For those who grant credit accounts, the adoption of such a system is invaluable. One very important advantage is the fact that, if posting has been done regularly, by simply adding each account, the bills are ready at the close of the month for mailing to the customer, thus enabling the proprietor to issue bills without delay and without special effort.

Double Entry Accounting—If the proprietor is using a double entry system of accounts throughout, the "personal accounts", that is, the record of the sale to the retail customer and the payment on these sales, may be handled as already described under the daybook, page 1392, but in posting them they must first be "journalized". This consists of determining the two parties to the transaction, the one to be debited and the other credited. In determining

this entry the bookkeeper may advantageously ask the question with reference to every transaction, "Who is in debt"? The person or account "in debt" is of course debited, the other party to the transaction is credited. If this question is asked for every transaction, it will always give the clue to proper journalizing.

Journalizing—For the beginner it is desirable to write out this journalizing step, as illustrated in Figs. 483 to 485. When properly journalized, the transactions are then posted in the ledger. It can be seen that the account of a customer making a purchase is marked with the abbreviation, "Dr."

The journal

indicating the debit side of the ledger and the credit side with the abbreviation "Cr."

The account supplying the goods for the sale is primarily known as the "merchandise" account, and this account is accordingly credited whenever a sale is made. This merchandise account may be subdivided into as many classifications as are desirable. For instance, it may be represented by various departments as drugs, soda, cigars, candy, etc. In this case, the credit when a sale is made in any one department, would be entered to the credit of the department involved.

When a bookkeeper becomes skilled, the actual writing out of the journal becomes unnecessary. Then the original entry may be journalized mentally and posted at once in the correct ledger accounts.

The Cashbook—The only kind of cashbook which any retail pharmacist should use should be double entry in character. In other words, the cash

account should always have a debit and a credit side. The cash account should be comprehensive. It may be that a petty cash account may be carried on the side, in which are entered small expenditures and even receipts, but the combined "cashbooks", should record every transaction in which cash is involved and its balance should show "total cash". (See Figs. 450 to 453.)

Journalizing in the cashbook is sometimes confusing to the amateur but, if the "cash account" is considered as occupying the position of an official, say a treasurer, who is responsible for the money of the firm and who must be prepared at any time to report the balance on hand, it will then be seen that this account or individual is in debt or is debited whenever money is received. Likewise this account, or this individual representing the business, must be credited whenever money is paid out. If a complete record of every cent received by the business from whatever source is kept on the debit side, and if, on the credit side, is a complete record of every expenditure, no matter how small, the "balance", that is, the difference between the debit and credit side, will always indicate the cash on hand. This cash, of course, may be in various forms. Some of it may be in the cash register of the store, another portion may be in the store safe, and the remainder may be in bank or even invested, but the cashbook, when closed or balanced, should indicate accurately the total cash available.

The journal

The entries in this form of cashbook are usually chronological and constitute the "original entry". It may be, of course, that money received on account may be entered upon appropriate slips and rung up on the cash register during the day and subsequently entered in the cashbook. In such cases, the original slip becomes the "original entry". This cashbook must ultimately be posted to the ledger. The debit side is posted first and every transaction involves at least two parties.

If the money received in the business has come from the sale of merchandise, the two ledger accounts involved are cash and merchandise. Cash is debited as having received the value and merchandise is credited as the account supplying the goods sold. If a customer has paid money on account, the accounts involved are: first, the cash account, which is debited as having received the value, and second, the personal account of the customer who is given credit for the payment. In a transaction representing the payment of a bill for supplies, the personal account of the firm supplying the goods will be debited and the cash account, representing the cash paid out, will be credited.

If rent has been paid, the rent account, perhaps under the name of the

Cashbook

owner of the property, will be debited, and cash will be credited. If a salary has been paid, the salary account, perhaps divided into an account for each employee, will be debited and the cash account again credited. Thus every entry in the cashbook will be appropriately journalized and entered on the debit or credit side of the proper account in the ledger.

The Ledger—The ledger consists of a systematic summary of every transaction. When records are transferred from the books of original entry to the appropriate account in the ledger, the act is spoken of as "posting" and the account is said to have been "posted". When the records have been properly posted, there will be found in every account, all transactions involving that account, the entries being divided into debits and credits. Ledger entries are illustrated in Figs. 490 to 497.

The Trial Balance—When properly posted, at the end of a stated period, it is customary for the bookkeeper to take off what is known as a "trial balance". This consists of tentatively closing every account with a pencil addition of both Dr. and Cr. sides and a subtraction, so that the balance in every account may be determined. All debit balances are then added, and also all credit balances and the totals of both should be identical. This is simply a mechanical check upon the fact that "for every debit there has been a credit". It does not conclusively prove that the books have been properly posted. There is always the possibility that a debit and credit may have been reversed, but it is a valuable first check upon the correctness of entries.

Closing the Ledger—In obtaining more valuable information from the ledger concerning the status of the business, the accounts are now divided into two groups. These are usually spoken of as "personal" accounts and "speculative" accounts.

"Personal" Accounts are those which are mere records of transactions. One type is when goods have been purchased by a credit customer and then paid for; the account closes without a balance. Others are simply records of money received and money paid out and the balance is a simple statement of cash on hand. Personal accounts are supposed to involve no profit or loss. They are simply a record, though an important one, of various transactions of the business.

On the other hand, *speculative accounts* are those which involve the possibility of a loss (in many instances an expense), or a gain. Many of these accounts are simply the expense accounts necessitated by the conduct of business, such as rent, salaries, light, heat, etc. Other speculative accounts are of a different character.

The *merchandise account*, for instance, whether standing for all merchandise sold, or divided into departments, is an account which should show the gross profit or gain, in fact, this account is the true speculative account. In a properly organized business it should show sufficient profit to cover all expenses, and in addition, should leave a balance of net profit for the proprietor.

The next step in closing the ledger must be the entry, in all accounts involving an investment, of the correct inventory. For instance, the merchandise account must be credited with the goods on hand before a true statement of profit or loss can be determined. The heating account will usually carry an inventory for fuel on hand. The fixture account would, of course, be credited with an inventory of the present value of fixtures and there will doubtless be other accounts with an inventory.

Wherever value is found in accounts it must be credited before the closing of the books. This entry is usually made in red ink on the credit side.

The ledger

A *statement of profit and loss* must now be made (see Fig. 498). This consists of gathering together the gross profits, that is, the difference between the cost of the merchandise and the credits for their sale, plus the inventory. Then the expenses or losses must all be assembled. The difference between the total profits, which is spoken of as *gross profit*, and the expenses and loss, for the same term, will yield the "*net gain*", or perchance, "*net loss*". This net profit (or net gain, if the expenses have exceeded the gross profits) is now entered in the capital account.

If there has been a net profit, the capital account is credited with the amount. If it is a loss, the capital account is of course debited.

Statement of assets and liabilities

A general statement is now necessary which is termed a *statement of assets and liabilities* (see Fig. 499). All ledger accounts are now closed and the balances brought forward. In the case of accounts involving an inventory, the individual accounts, when closed, are debited to the inventory in opening the account for the next period.

The resources are now all assembled, including such items as cash, merchandise inventory, fixtures, and all other inventories, unpaid credit sales, goodwill, etc. The liabilities are also assembled. These would consist of such items as unpaid invoices, promissory notes, etc. The difference between the resources and liabilities should then be determined and this should equal the total of the capital account, if the previous statement of net loss or gain has been entered thus proving the correctness of the accounts and providing the proprietor with valuable facts concerning his business (see Fig. 498).

The Adding Machine

The adding machine is an extremely useful accessory in any drug store. It makes it possible to obtain accurately, quickly, and conveniently all figures pertinent to the successful operation of a business

Some of the more common uses for an adding machine are as follows:

Making up the bank deposit slip.

The balancing of bank statements.

The checking and proving of incoming invoices.

Analysis of sales by departments, or clerks, or both.

Departmental inventories.

Handling counter sales, both *cash* and *charge*, where several invoices are involved.

The segregation of expense items.

The taking of a trial balance.

The proving and balancing of ledgers.

FIG. 500

Adding machine

The machine illustrated in Fig. 500, made by Burroughs Adding Machine Company, has a carriage, similar to that on a typewriter, for accommodating wide forms. This makes possible the use of any special forms desired.

A Columnar System of Accounting

The individual drug store proprietor, who keeps his own books, is apt to feel that the kind of bookkeeping which would give him results such as those just discussed is too complicated for his own use. It is true that to obtain these results by the usual double entry methods is a task which requires considerable time as well as technical knowledge of bookkeeping.

To meet this condition a simplified accounting plan has been developed for the retail druggist by the LaWall Systems of Philadelphia, Pa. One important advantage of this plan is that no technical knowledge of bookkeeping is necessary to operate it, although results fully as useful as those obtainable from the most complete sets of double entry books are obtained. Moreover, specially designed sheets make it possible for a druggist to obtain these results with a minimum of effort and time. The following pages contain a description of how records should be kept to obtain such results, starting with original entries and tracing them through to resulting profit and loss statements, financial statements, and comparisons. As mentioned, the druggist need have no technical knowledge of bookkeeping to maintain and understand records kept in this manner. The LaWall Systems of Philadelphia, Pa., owners of the patents, have graciously given their consent to the reproduction of many of their specially designed record sheets in connection with this explanation of their modern system of drug store bookkeeping.

Original Entries—*Cash Totals*—A special form (Figs. 501 and 502) is used to provide a convenient and easily compiled record of daily cash totals. A pad of these forms is kept at the cash register and each night when the store is closed the day's figures are entered in the appropriate columns. Space is provided on the form for recording separately (in columns A to F) the business of 1 to 6 different departments.

Cash Paid Out—Another original entry form may be merely a memorandum book in which are recorded the details and amounts of any cash paid out during the day. Such entries are made, of course, at the time the money is paid out. In some stores each item of cash paid out is recorded on an individual slip of the type shown in Fig. 478. A pad of these slips is kept in the cash register. As a safeguard the cash register is used to imprint the amount upon the slip. Thus a check of the cash register record would show any slips missing. In stores having receipt-printing cash registers, a common practice is to ring the amount paid out on the register and then mark on the receipt the purpose for which the money was paid. These paid out receipts are kept in the cash drawer until permanently recorded in a book to be described later.

Sales Charged—When a sale is made for which cash is not received immediately, a record of the sale must be kept, at least until the goods are paid for. Serious losses result from a disregard of this simple fact. (See page 1392.)

Money Received On Account—When the charge sales just described are paid for, the cash received is recorded as money received on account. It is a payment for sales previously made. A slip such as shown in Fig. 479 may be used for recording each payment on account. The name of the customer and the amount paid are written in in the space shown and, as a safeguard, the slip is imprinted with that amount on the cash register. In the stores which use the memorandum book for cash paid out and charge sales, money received on account may also be recorded in this book. If the store is using a monthly billhead with a detachable coupon (see Fig. 446), this coupon (which already has written on it the name and address of the customer and the amount of

the bill) is mailed or brought to the store by the customer with his remittance and serves as the store's record of the payment of the account. As a safeguard, it likewise should be imprinted on the cash register with the amount paid.

Bank Book—The bank book is a receipt book in which the receiving teller at the bank records all money (cash and checks) deposited to the credit of the store.

Checks Issued—A simple method of recording and classifying checks issued is shown on the LaWall plan Daily Record Sheet (see Figs. 501 and 502). This method is explained in the description which follows of the Daily Record Sheet.

Daily Record Sheet—As previously explained, the Daily Cash Balance Sheet (Fig. 503) provides a convenient form on which to record the daily cash totals of the business. Once these figures are recorded the next step is

to classify them so that they can be interpreted and compared. The use of a "Daily Record Sheet" (Figs. 501 and 502) accomplishes this. The numerous columns provide a ready means of classification.

One of these Daily Record Sheets provides space for a complete record of a day's business: money taken in and what it was taken in for; checks and cash paid out and what they were paid out for. The figures for this record are posted from the original entries just listed.

The left hand side of the sheet provides the following record of receipts:

Cash sales, charge sales, and total sales by departments.
Cash received on account of charge sales.
Other cash received (as from upstairs rooms rented).
Cash on hand in the store from the previous day.
Cash in the bank.
Bank deposits made during the day.

The right hand side of the Daily Record Sheet is a record of payments:

Cash paid out and the purpose for which it was paid. The original entries are posted item by item and the amount entered in the proper expense column. For instance, in posting an item of 75 cents for oranges, the word oranges would be entered under the column headed "Description" and the amount, 75 cents, in the column "Total Paid Out". While entering the amount in this column it is the work of a second to enter it also in the column "Merchandise", this indicating the purpose for which the money was spent. Similarly an item of $1.24 paid the express company would first be recorded in the columns "Description" and "Total Paid Out" and then the amount $1.24 also entered in the column "Freight, express, and hauling".

Checks paid out and the purpose for which they were paid. Payments by check are entered and distributed in exactly the same way as cash paid out. As a matter of fact, this part of the Daily Record Sheet may serve as an original entry for checks issued, the record corresponding to that which usually would be made upon the check stub.

The bottom line of the Daily Record Sheet summarizes the day's business. In addition to showing the details of receipts and expenditures, this space is provided for totaling and summarizing them. To the proprietor who wants to see at a glance the significant features of a day's business, the importance of this summarizing is apparent.

Customers' Charge Accounts—The Daily Record Sheet provides a record day by day of the total amount of charge business done, but does not show the names of the individuals with whom the business was done or the amounts owed by each. It is possible to obtain with one writing a record for the store of the amount owed by each customer and a bill or statement for the customer showing the same facts (see Fig. 482).

Accounts Payable—Accounts payable is the term applied to bills which the store itself is to pay. They arise of course out of the purchase of merchandise for sale and other items of expense incurred in the conduct of the store. When such items are paid immediately, the record of the transaction is furnished by the cash paid out slip or the statement of checks issued in the Daily Record Sheet.

As in the case of customers' charge accounts, however, the store itself frequently makes purchases which are to be paid at a later date. A special record of these transactions must be kept. The Invoice Record, shown in Fig. 504, is a simple, convenient method of keeping such a record.

Bills are entered as they are received, one on each line of the Invoice Record. Space is provided on this line for entering the gross amount of the bill, its date and the date on which it is to be paid if a cash discount is to be earned. When the bill is paid, the cash discount, other deductions, and the number and date of the check are entered in appropriate columns. Thus this one line on the Invoice Record forms a complete record of the transaction. Moreover a glance at the Invoice Record at any time shows the amount of unpaid bills and also the dates on which they must be paid if various cash discounts allowed are to be earned.

The Invoice Record Sheets are punched at the top to fit a post file, on which the unpaid bills themselves are also placed in alphabetical order. The reason that a store should make its own record of accounts payable, in addition to the record formed by the bills themselves, is that the bills themselves

FIG. 504

"	Knight Cigar Co.	12/20	120 62			2 41			

are awkward to handle for quick reference and, more important, if a bill should be lost or misplaced, a sizable cash discount might be lost because the bill to be paid could not be found. Again a vendor might send two bills for the same purchase; if the bills themselves form the only record, there is the possibility that the purchase would be paid for twice.

Monthly Record Sheet—The Daily Record Sheet (Figs. 501 and 502) shows on one double page a detailed record of a day's business. For comparative purposes it is desirable to bring together the totals of the various classes of receipts and expenditures for each day's business. This is accomplished by the use of the monthly record sheet shown in Figs. 505 and 506.

This double page shows day by day the totals of the various classes of receipts and expenditures for an entire month. For instance, the totals for the first day of the month are entered in the appropriate columns on the line marked. To lessen the number of figures presented in this example the total of several days of business have been combined. In ordinary practice, however, the figures would be entered each day.

The second day's figures are entered on line 2. Following line 2 and each of the other lines numbered for the days of the month is a line which provides space for a cumulative record for each of the classes of receipts and expenditures. This cumulative record makes possible on any date comparisons of various classes of receipts and expenditures, not only for the current month

but for corresponding periods of other months. For instance, the proprietor with this cumulative record, can compare at a glance purchases and sales, total expenses or any one of several classes of expenses on the twelfth, the twenty-first or any other day of the month with each other or with the similar figures for corresponding days of other months. It is not necessary to wait until the end of the month or year to make such comparisons. The use of this columnar classification makes possible these comparisons at any time.

Inventories creep up unless carefully watched and are very apt to cripple the ability of the retailer to take advantage of cash discounts. A simple method of watching the inventory is to compare the totals of sales and purchases on the

monthly Record Sheet (Figs. 505 and 506). Suppose the total purchases up to the twenty-fourth of the month amount to $1600, and the total sales up to that time in the month have been $2000, the gross margin upon which the store has been operating is 33 per cent of sales. Sales of $2000, therefore, show us that purchases should have been $1333, consequently the proprietor has over-bought $267. From that day until the end of the month he must try to confine his purchases to little or nothing in order that the month may wind up properly.

Sales Totals—Sales of each day should be compared with the same day of the previous year. A comparison of weekly totals and also of monthly totals with the previous year should be made. These sales totals when taken together with the cash register record showing the actual number of transactions are very valuable.

The important thing in a business of any kind, after all, is to know the best points and to create more of them, and also to know the weak spots so as to eliminate or avoid them. Figures by themselves will not always show this, but a comparison of figures will often point them out.

Yearly Record Sheet—The Yearly Record Sheet (Figs. 507 and 508) is the logical development of the Monthly Record Sheet. Column headings correspond to those on it. The figures on the last line of the Monthly Record Sheet form the monthly totals, which when transferred to the Yearly Record Book Sheet give a month by month record of receipts and expenditures for the year's business.

Inventories—In a drug store, a physical inventory is an expensive and time consuming task. In fact many druggists say that an inventory accurate to the last penny is impossible to obtain in a drug store. The amount contained in a partly filled shelf bottle, for example, is difficult to determine unless the contents are taken out and measured and if this is done the loss in measuring valuable drugs, may very well be the profit on several dollars worth of sales. However, in almost any store it is possible to determine within the limits of a few hundred dollars the amount of goods on hand. The following example illustrates why such a measurement is necessary.

Druggist Black's annual sales are	$100,000
The goods he purchased during the year	50,000
His expenses amounted to	30,000
Apparently his profit is	20,000

On the face of this report, druggist Black appears to have been extraordinarily successful. But consider this: suppose an inventory of the goods in his store at the beginning of the year for which the figures above are given totaled approximately $20,000, whereas another inventory at the end of the year showed a total of only $10,000. Actually, therefore, Druggist Black had sold during the year not only the $50,000 worth of goods which he had purchased but also an additional $10,000 represented by the decrease in the stock of goods on hand. His real profit is not $20,000 but $10,000.

Correspondingly, a showing of profit less than that actually earned would result if an extraordinary increase in the amount of goods on hand occurred

during the year. It is thus apparent that when marked changes occur during any year in the amount of goods on hand a new inventory is necessary in order to get a correct idea of the profit earned.

Once a store is well established, however, such violent fluctuations in inventory should not occur. Milk of magnesia, for example, may be bought in half dozen lots from the local wholesaler. When four bottles have been sold, another half dozen is ordered. This process is repeated indefinitely and occurs not only in the case of milk of magnesia but also in the case of all the other thousands of items stocked by the retail drug stores. When the stock of goods is reduced to this relatively stable basis, the stock of goods on hand at any time can be calculated in the following way:

		Per cent
Suppose sales last year were	$50,000	100
Cost of goods sold	30,000	60
Expenses	15,000	30
Net profit	5,000	10

An inventory at the beginning of this year totals	$25,000
Purchases this year total	31,000
Total	$56,000
Sales this year were $52,000 and on the average these goods cost 60 per cent of their selling price or	$31,200
Therefore, stock on hand at the end of this year is	$25,800

If the stock of goods on hand is known to fluctuate very little, a physical inventory need be made only occasionally to compare the calculated figure with the amount of goods actually on hand (see also Inventories, page 1352).

Profit and Loss Statements—With the inventory determined within reasonable limits, the calculation of profit or loss becomes an easy matter. The use of the form shown on the Yearly Record Sheet greatly simplifies this work. If the proprietor has kept his records in the form described in the preceding pages, he can, with a few minutes' work, determine his profit, not only annually, but also monthly or even daily.

Financial Statements—The profit shown by this Profit and Loss Statement will not be necessarily in the form of cash. This is a point at which considerable confusion and misunderstanding occur. A proprietor may calculate that his business earned a net profit of $3500 and still have only $1000 in the bank and numerous bills yet to be paid. To prove the accuracy of the Profit and Loss Statement, it then becomes necessary for the proprietor to take account of all the resources he has and also every liability standing against him. This he can do conveniently in the Statement of Assets and Liabilities which appears in the lower right hand corner of the Yearly Record Sheet (Fig. 508).

As assets, he first considers the cash on hand or in the bank, then his stock of merchandise, his fixtures, including the soda fountain if he has one, office supplies, coal, and other usable goods. He also includes any paid up insurance policies and securities which he may hold.

Goodwill is sometimes also included as an asset, but because of its intangible and transient nature it is not always considered wise to attempt to place a dollar value on it.

Depreciation—Depreciation is a measure of the loss in value of an asset.

Soda Fountain Depreciation—The life of a soda fountain is not dependent upon its wearing out but is rather dependent upon how soon it may become out-of-date. The average soda fountain becomes obsolete within five years, and to use the older type of fountain after that period very often makes it a liability. Depreciation on the soda fountain should really be at the rate of twenty per cent a year.

Fixture Depreciation—This is rather a difficult subject because as a matter of fact well-made fixtures will practically never wear out. The average life of a drug store, or rather we should say the average period of life for the drug store before it sells out, moves, or the proprietor dies, is seven years. On an average then, there must be a re-adjustment of fixture and fountain valuations every seven years. A specially made fixture is seldom of any use in another room, and, consequently, its value the day it is put in is about 50 per cent less than its face cost. Whereas, with absolutely standard interchangeable unit fixtures, there is a substantial use-value because it cannot only be placed in another drug store, but it can be adapted to fifty different kinds of retail stores with the result that it does not lose its face value, and 5 per cent per year is plenty of depreciation to figure.

Another factor in the use of interchangeable unit fixtures is even more important, namely, that of having the ability to re-arrange departments inside the store. Changes are often required in arrangement in order to make the most economical use of clerks, floor space, and also to get the best sales returns out of the customers. The ability to interchange units or add to them keeps the value of standard units always fresh as they can be moved or changed about with practically no cost and as easily as household furniture may be arranged.

In purchasing a drug store the value of fixtures and soda fountain should be estimated not according to their initial cost but rather according to their use-value. Pharmacists sometimes pay $5000 or $6000 for an equipment that not only is obsolete but also is an actual *liability* to the business, whereas they might have installed a totally new equipment for $2000 or $3000 and have it efficient in every way.

A fixture should be considered simply as a piece of machinery that will enable the proprietor of the store or his assistants to give the best possible service to his trade. When that machinery is so badly designed or arranged in the store that its use-value is negligible, then the price of those fixtures should be

set not according to the marble, wood, and trimmings that are on them, but exactly according to the value that they are going to have when the store is put on an efficient basis.

A factory owner in taking over an old plant will consider an obsolete machine as a liability, and when retailers get to figuring this way, they will reach a better business basis.

Stock Depreciation on Merchandise—The inventory of the store suffers from breakage, leakage, spoilage, or from becoming out of date, and it is considered good business to estimate two per cent depreciation on inventory, or set up a reserve to meet such losses as are bound to occur in the normal store.

In addition to the assets already listed, all customers' unpaid accounts and other money owing to the proprietor should be included. If any of the customers' accounts cannot be collected, they should not be considered as assets any longer but should be deducted and charged as an expense of conducting the business.

The liabilities are listed on the right hand side of this balance sheet. They consist principally of unpaid bills and any other money owed by the proprietor.

It is possible now to prove the accuracy of the Profit and Loss Statement. If the total of the money owed plus the capital invested in the business plus the net profit shown for the year equals the total of the assets, the result is correct.

The financial statement is a measure of the strength of a business.

Naturally if the margin between assets and liabilities is low the proprietor's equity in the business is small and might be wiped out by a few unprofitable months. Such a store would be a poor credit risk.

The store having records which permit the quick and accurate compilation of a financial statement has a great advantage. For example, the opportunity may come suddenly to buy the store building. Few stores would have on hand the cash to finance such a proposition but a financial statement, based upon such accurate records as those described in the preceding pages, would show the financial strength of the store and convince a banker of the credit which could be extended legitimately for the transaction.

The banker is guided almost entirely by a financial statement, and more especially by a comparative statement of years or months because this "*comparative statement*" shows the trend of the business.

It is important to note that if a banker can tell so much more about a store by looking at a *statement*, than he can by making a detailed inspection of its stock, fixtures, location, prospects, etc., then it surely behooves the owner to pay a little more attention to these vital figures. Some day we will see groups of retailers making comparisons of these vital figures and learning from one another what they could never learn from a study of their own figures. An example of an undertaking of this kind is illustrated by Fig. 509. This is a reproduction of a questionnaire sent to its members for this purpose by the Philadelphia Wholesale Drug Company, a coöperative association of retail druggists.

Valuable Information from Accounts

When accounts have been closed and the proprietor has before him the financial facts concerning the business, covering a stated period, he should fully utilize these. Exceedingly important information to determine at once would be the per cent relationship of the cost of merchandise sold, the expense of conducting business, and the net profit, all in relation to the total sales.

Strictly Confidential

FIG. 509

DRUCO

Note: Please answer every question. This is necessary in order to get facts which will be the most practical help to you.

Census of Business Costs—1925 No 2152

Twenty-five to forty cents out of *every* dollar a druggist takes in, he pays out again for operating expenses. Before these expenses can be reduced, present expenses must be known. That is the object of this inquiry. The figures you send in will be used *only* to make an average of operating expenses of drug stores in Philadelphia and vicinity. When it is known what it costs on the average to operate a drug store, an individual proprietor is in a position to compare his own results with the average of all; to see where he is weak and where he is strong in comparison with the average. He can then act intelligently to cut down the expenses which are too high.

Promptness in returning this sheet is vital; the sooner we have your facts the sooner you will have the results. If at all possible sit down now and fill it out immediately or have your bookkeeper do it for you. Then return the white sheet in the inclosed envelope by the next mail. Keep the yellow copy for your records.

Sales
Total sales for 1925. $.....
Can you say what per cent are charge sales?.....
(Per cent)

Salaries
Total amount paid in 1925 to people who work in the store in wages, commissions, and bonuses. Do not include deliverymen's wages as they are shown below under "Delivery".
How many people do you employ in the store?..... $.....
(Number)

Rent
Actual amount paid as rent for the year 1925, including any taxes, assessments or insurance that you pay for the owner. If you own your building, you should put down what the store would rent for to someone else and also include taxes, assessments and insurance that you pay on it, and mortgage interest. $.....

Light and power
Total of your electric (or illuminating gas) bill in 1925. $.....

Heat
What you spent in 1925 for coal (or oil and gas). $.....

Insurance
Insurance on stock, fixtures and equipment; liability insurance; life insurance on members of the firm if paid for out of the business and issued for the business. Do not include fire insurance on the building. $.....

Taxes
City, county, state and government taxes on stock, fixtures, equipment. Do not include income or luxury taxes or taxes on real estate. $.....

Interest
Interest on money borrowed for use in the business. Do not include interest on your investment in the business or interest that you may pay on mortgages on the building. $.....

Losses from bad debts
Total amount of bad debts you charged off during 1925. $.....

Repairs
Expenses for repairs to building and store equipment in 1925. $.....

Depreciation
Depreciation is the *decrease* in the value of fixtures and soda fountain. Suppose, the fountain you bought three years ago you figure will last you just about another three years. Therefore, in each of the six years you have it in your store it loses one sixth of its value. This loss in value each year is a legitimate expense to be charged as part of the cost of running your business. You can estimate similarly the life of your other fixtures. Simply divide the length of time you expect to use them into the price you originally paid for them and you have the amount of depreciation you should charge off each year. Include here the total amount of depreciation you charged off in 1925 for both fixtures and fountain. $.....

Delivery
Wages of messengers and deliverymen, parcel post, express and car fare spent in delivering merchandise you sold; bicycle expenses and costs of operating a delivery automobile, if you use one. $.....

Advertising
Cost of advertising in publications, street cars, billboards, etc. Also circulars and circular letters, calendars, and expenses in decorating windows. $.....

Owners' or managers' salaries
Total amount paid a manager or taken out of the business by owners as salary or payment for services. You are entitled to at least as much salary as you would have to pay a manager to operate the store for you, or as much as you would earn working for someone else. Do not include, however, dividends or withdrawals of capital $.....
How many owners are active in the business?.....
(Number)
Is the amount you list here also included under the heading "Salaries" above?.....
(Yes or No)

Miscellaneous
Includes stationery and office supplies, wrapping paper, brooms, soap, towels, coats and aprons and other store supplies, donations, dues in trade associations, trade paper subscriptions, telephone and telegraph, thefts, lawyer's fees, and any other expenses not previously listed. $.....

Merchandise bought during 1925
Total cost of merchandise bought in 1925. $.....

Merchandise stock December 31, 1925
How much merchandise had you on hand at the end of the year (December 31, 1925)? If you took an inventory about that time use that figure. $.....
Is the value of your stock figured at *cost* or *selling* price?.....
(Which?)

Merchandise stock January 1, 1925
How much merchandise did you have on hand the first of *last* year? Use the inventory figure if you took one about then. $.....

Note: If you have more than one store, please use a separate blank for each store. Let us know if you need more blanks.

Percentage Comparison—The reduction of the Profit and Loss Statement to percentages makes possible many useful comparisons.

The "total sales" must always be considered as 100 per cent. *This is the only basis for satisfactory calculation*, because on this basis it is possible to arrive at percentage relationships from the annual business, which can then be used for comparison from day to day throughout the entire succeeding year. This is because the sales and expenses are always definite figures which may be known daily, while the cost of goods sold is difficult to determine. This basis for calculation for per cent comparisons is almost universally adopted today in the business world.

With the taking of an inventory and the final closing of the bookkeeping record, which in many businesses is only done annually, it is possible to determine the actual "first cost of merchandise sold". This is then compared, on a percentage basis with total sales and total expenses, and the actual profit or loss percentage determined for the period under examination. Figures often given for an average successful business are about 65 per cent for first cost of goods; 25 per cent for expenses, and 10 per cent for net profit, making total sales 100 per cent. If the figures for any one year do not show something like this relationship, the business man may take the necessary steps to bring about a more satisfactory ratio.

If the net profit is greater than indicated here, there is, of course, no need for concern. The proprietor is very fortunate. However, if the expenses are much higher in their per cent relationship to sales, and net profit much lower, the proprietor has the necessary evidence to stimulate his efforts toward readjustment. It may be that he will have to reduce expenses if that is practicable. A study of these may show him where some expense is excessive. On the other hand, he may find that the expenses cannot be reduced. Then he has the alternative of increasing the sales, which would materially reduce the per cent relationship of expenses to sales unless he is compelled, because of the increased sales, to add proportionally to the expense of the business. In almost every business, up to a certain point, more goods could be sold without greatly increasing the expense because most of the fixed costs would remain the same, such as rent, light, heat, etc. There would probably be some increase in advertising and, possibly, in salaries.

The proprietor also may improve the situation by eliminating goods which are showing small profit, or even loss, and replacing these by more profitable merchandise; or perhaps, the cost of regular goods is not being carefully watched, and that by more careful buying, or buying under different conditions, the margin of profit between first cost and the selling price may largely be increased. It is true that the selling price is often fixed by the buying public and trade conditions, and is not easily changed.

The proprietor is also in possession of figures which indicate to him the exact value of every sale. He is awakened to the fact that many articles that he has been selling freely have actually been passing over his counter at a loss. If he is wise, he will endeavor to curtail such sales, only permitting those which are actually necessary to please customers, and will, on the other hand, select merchandise which gives a reasonable profit, and advertise and sell these in preference to the less profitable lines.

He will also recognize the importance of adding an adequate profit to the cost of professional work. In other words, by knowing the figures which represent "cost of goods" and "overhead", the proprietor will gain a control of his business, which had not been possible heretofore, and which may be

utilized to insure definite and dependable profits, so that from month to month it may be known whether the business is profitable or otherwise.

In determining the percentage relationship of sales, total cost of goods, expenses, and net gain in any one department, such as at the soda fountain, the candy counter, or the cigar case, the ordinary retail drug store is somewhat handicapped because of the difficulty of proportioning properly the general expenses. Purchases, of course, can be kept separate, and some expenses will be assigned definitely to a special department, such as laundry, or special clerks, but the division of rent, light, heat, etc., among the several departments calls for good judgment and some study in each store. The floor space required for each department is usually the basis for this division of expenses. The front part of the store must bear the larger percentage. To obtain greater value from the rear and other parts of the store many proprietors introduce in these locations attractive features which are intended to draw customers. The drug and prescription counter, and telephone booths are especially effective.

Sometimes the front of the store, back one-fourth, is expected to bear at least one-half of the general expenses. The second fourth of the sales room would then carry one-fourth of the expenses, while the last half of the sales room would be expected to pay the remaining expenses. Thus if the soda fountain were in the front of the store, it would be expected to pay its share of the expenses in the ratio indicated; if half way back, though occupying no smaller space, it would pay much less. Of course, this ratio must be determined by each proprietor and upon this the actual net profit in any one department determined.

Finally, it has been demonstrated by wide experience, that facts such as these, if available for business, give a satisfaction and control to the proprietor which amply justify the comparatively small amount of labor required, and changes the business from a guess to a definite profit-making machine, the control of which is in the hands of the management to manipulate almost at will.

The following hypothetical example of Druggists Jones and Brown, graphically illustrates the importance of correct accounting records:

	Jones' Drug Store		Brown's Drug Store	
Annual Sales	$50,000	100 per cent	$45,000	100 per cent
Cost of Goods	35,000	70 per cent	35,000	77 per cent
Expenses	12,500	25 per cent	7,500	17 per cent
Profit	2,500	5 per cent	2,500	6 per cent

Both Jones and Brown apparently have made the same profit, although Mr. Brown's records show he did $5,000 less business. As a matter of fact, Brown did just as much business as Jones but failed to keep track of some of his expenses, with the result that apparent sales totaling $45,000 really were $50,000 because, $5000 had been paid out in the course of a year for expenses and no record kept of it. (Incidentally, such an occurrence is not at all unusual.)

But, as the two statements show, both earned the same profit in their business; what is the harm in such a situation? Jones knows that to make his intended 5 per cent profit on an article, his cost of that article must not exceed 70 per cent of the selling price. Goods that he purchases for $8.00 he must sell for at least $11.50. As a matter of fact, the cost of Brown's goods also should not exceed 70 per cent of their selling price, but the wrong notion

of his expenses and profits which he has obtained from his failure to record properly his expenses leads him to believe that his cost of doing business is 23 per cent and not 30 per cent, the same as Jones. This false notion of his cost of doing business leads Brown to believe that the goods he buys for $8.00 he can sell for $10.40 and make his usual profit. Such a sale is an actual loss, as the following example shows:

	Supposed result
Selling price	$10.40
Cost of Goods	8.00
Supposed Expenses	1.77
Supposed Profit	.63

	Actual result
Selling Price	$10.40
Cost of Goods	8.00
True Expenses	2.60
Loss	.20

Very evidently, a repetition of such sales leads inevitably to a depletion of stock and cash and finally to bankruptcy.

The National income tax laws have required that records be kept so that the tax on net income could be determined correctly. Any failure to charge expenses correctly therefore leads not only to a false notion of the cost of doing business and consequent errors in pricing, but also may cause an overpayment of income taxes, through a failure to keep a full record of legitimate expenses.

Constructively, the maintenance of accurate and adequate records and accounts gives the retail druggist many opportunities to increase his profits. The following example illustrates this fact:

Suppose, annual sales are	$50,000
Cost of goods is	35,000
Expenses	12,500
Profit	2,500
Suppose, annual sales remain	$50,000
Cost of goods is still	35,000
But expenses reduced to	12,000
Profit then becomes	3,000

Thus a 4 per cent reduction in expenses results in a 20 per cent increase in net profits.

The retail druggist will agree that in management the problem of diagnosis is much more difficult than that of treatment.

It is easier to cure a known difficulty than it is to find the difficulty. A mechanic may spend hours looking for the cause of an automobile's failure to start and only a few minutes in correcting it once he has found it. Accurate and dependable records enable a druggist to see the strengths and weaknesses of his business. He then is in a position to act quickly and intelligently to control them. He will see when his payroll climbs too high, when he buys too much, when his customers are not paying their bills as they should, and a thousand other facts which he knows are warning of dangers ahead.

ACCOUNTING—A RECORD OF PROGRESS

One of the principal advantages of keeping drug store records under the plan just described is the fact that the proprietor has constantly available the exact conditions of his business. Trial balances and other preliminary calculations are unnecessary.

The value of any accounting records lies in their interpretative use. The following tabulation indicates how the proprietor can readily measure his part progress, and on the basis of these records plan intelligently for the future. With these facts before him, he can see the places at which he is weak and lay plans to strengthen them. He also sees the strengths of his business and therefore can proceed knowingly to intrench himself in these respects.

The following are the facts which should always be available for the proprietor of a pharmacy who desires to intelligently control the finances of his business. He should insist upon obtaining such figures regularly and in comparison with those from previous months or years.

1. *Net Sales*—Compare with previous corresponding periods, by departments and totals. Compare also with total cost of merchandise.

2. *Total Charge Sales*—Compare total outstanding accounts with the amount paid on account to determine how rapidly they are being collected.

3. *Total Cash Receipts*—Compare cash receipts with total cash paid out.

4. *Total Cost of Merchandise*—Compare cost of merchandise with total net sales to determine gross margin. Compare also with previous corresponding periods.

5. *Total Expenses*—Compare total expenses with previous corresponding periods.

6. *Net Gain or Loss*—Add the total for cost of merchandise to the total for expenses and subtract this sum from the total net sales for the same period. The result is the net gain or loss for the period. Compare this result with the result for previous corresponding periods.

7. *Total Cash on Hand*—Compare with cash on previous dates.

8. *Total Unpaid Bills*—Compare with the corresponding figures for previous dates.

9. *Inventory*—Compare with previous inventories. If no inventory has been taken it is possible to make an estimate by the method explained on page 1354.

10. *Comparison with Averaged Results of Other Stores* (see page 1421)—By converting the figures to percentages, the proprietor is in a position to compare his results with the typical results of other stores.

PART IX

THE PHARMACIST AS AN ANALYST

CHAPTER LXXXV

THE QUALIFICATIONS OF A PHARMACIST AS AN ANALYST

THE pharmacist is primarily trained to manufacture, compound, and dispense medicines. This has been his opportunity and responsibility through centuries of service, a service in one of the most important of professional callings—that of aiding in the alleviation of suffering and in the prevention and cure of disease.

Pharmacists have played an important rôle in the development of chemistry and many notable discoveries and investigations have been made by apothecaries, working with meager equipment, in small laboratories, and with little in the way of library facilities, or knowledge of what had been done by others.

During the past few decades the practice of pharmacy has undergone some radical changes in the character of the professional work accomplished.

While still retaining the distinctive privileges and responsibilities of compounding prescriptions and dispensing medicines, the pharmacist has relinquished much of the responsibility of manufacturing to the large scale producer. This condition has been brought about partly for economic reasons and partly because of the increase in the number of chemicals and preparations which are difficult to make and still more difficult to standardize. A survey of the titles of preparations and processes which have been officially recognized during the first century of the existence of the United States Pharmacopœia will reveal this trend very clearly.

Processes were originally included for nearly all chemical salts and plant principles, in addition to galenicals and solutions. At the present time the pharmacist would not be warranted on the score of equipment nor on the grounds of economy in preparing many of the compounds which his predecessor manufactured as a matter of ordinary routine.

There are still, however, many preparations which may be easily and economically made by the pharmacist who wishes to continue in the line of manufacturing, but many pharmacists no longer take the time and trouble to prepare even these.

During this period of development of large scale manufacture, which has curtailed the professional work of the pharmacist in this direction, there has been no diminution of his responsibility for the character and integrity of the products which he employs in the compounding of prescriptions or of the drugs and medicines which he dispenses at retail.

Of all retail merchants the pharmacist is the only one who is scientifically trained in the art of identifying his wares and of detecting evidences of adulteration therein or deterioration thereof, and he may be, and frequently is, held legally responsible for not having exercised that knowledge.

The pharmacist is peculiarly well qualified on the basis of his professional knowledge and scientific education and training to act in the capacity of an

analyst, not only for his own protection, but as an opportunity for service to the medical profession and to the community in which he practices.

The practice of analytical chemistry, if only to a limited extent, keeps the pharmacist up to date in scientific learning and places him in the independent position of one who answers questions regarding quality and purity of the medicines which he sells instead of one who asks them.

The practice of analytical chemistry, also has remunerative possibilities, if carried on conscientiously and carefully, and the analyst is paid for the professional service which he renders just as physicians, dentists, and lawyers are paid.

The graduate of a course in pharmacy possesses the fundamental knowledge and training necessary for success in this line; all that he lacks is experience. If he is so inclined and makes good use of his opportunities, he may obtain this experience while carrying on his regular professional work, and in so doing he increases his scientific knowledge and elevates his professional standing in the community.

Equipment of a very moderate character may be used at the start, and as the need develops and opportunities occur a real laboratory can be built up in which work of the highest class may be performed.

The pharmacist's first duty, of course, is in the direction of the maintenance of quality and purity in such items of his own stock as are likely to vary from the standards, especially those which are apt to change on account of deterioration.

It is assumed that the pharmacist possesses a balance which is sensitive enough to serve for certain analytical procedures, particularly those connected with volumetric determinations of strength of a number of commonly used preparations which should be frequently tested and adjusted in this respect.

In a number of analytical determinations, based on volumetric procedures, no balance at all is required, all calculations being based upon measurements with pipettes and burettes.

Among the simpler operations are the following:

1. The titration of the official diluted acids and adjustment to standard strength.
2. The determination of strength of alkaline solutions, such as lime water, solutions of potassium and of sodium hydroxides and of the ammonia waters.
3. Estimation of strength of tincture of iodine, and Lugol's solution, etc.
4. Estimation of strength of hydrogen dioxide solution.
5. Estimation of strength of Carrel-Dakin solution, Labarraque's solution and Javelle water.

The foregoing list, comprising more than a dozen determinations, will require a very limited supply of apparatus and reagents, the minimum list being as follows:

One burette, graduated to $\frac{1}{10}$ cc.	Normal sodium hydroxide solution.
One 10 cc. delivery pipette graduated to $\frac{1}{10}$ cc.	Normal sulphuric acid.
	Tenth-normal potassium permanganate.
Three delivery pipettes of 5 cc., 10 cc., 25 cc. capacity, respectively.	Tenth-normal sodium thiosulphate.
	Phenolphthalein T.S.
Three beakers of assorted sizes.	Methyl orange T.S.
Three flasks of assorted sizes.	Starch T.S.

This complete outfit will cost less than $10.00 and no guide books or textbooks other than the U. S. P. and N. F. will be needed.

The addition of a few reagents and test solutions will increase the scope of the work to include the testing of most of the official liquors and the determination of purity of many of the official inorganic chemical salts.

If determinations of alcoholic strength are included in this initial list, a distillation flask, a condenser, and glass and rubber tubing will be needed, also an accurate pycnometer equipped with a thermometer. These items will cost more than the entire previous list, but if commercial determinations are made at standard prices for such service, the expenditure will soon be covered.

In order to develop confidence in one's work and at the same time provide for a check against error, particularly when carrying out a test for the first time, it is advisable to carry out two experiments in addition to the one upon the sample being investigated. One of these experiments should be arranged to give negative results and the other as to produce a positive reaction. For example, in testing for the presence of methanol in a specimen of alcohol, if three tests are carried out simultaneously, one upon a specimen known to be free from methanol, one upon a specimen to which methanol has been added, and one upon the unknown specimen, there need be no doubt in the mind of the analyst as to the interpretation of the results and such procedure will establish the correctness of the technic and the authenticity of the reagents beyond any question. The majority of careful analysts, as a matter of routine, follow this procedure every time an important test is made.

The pharmacist is frequently deterred from attempting to do analytical work or to check up official substances in the mistaken belief that every factor and every single test under each monograph must be included in the examination. Except in the rare instances where complete evidence must be presented, as in an examination leading to possible court procedure, this is not necessary. For example, it is rarely necessary to take the specific gravity of diluted acids, alkali solutions, etc., if the strength is found to be up to standard. Then too, many of the tests, such as the tests for heavy metals and for arsenic, which appear rather formidable when the text is first read, will be found to be very simple when actually applied as a matter of routine.

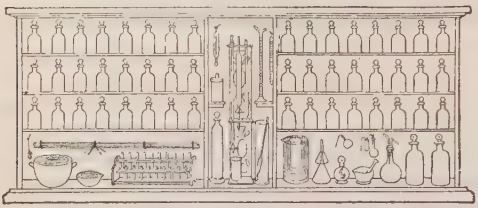
Selective preference may be given to the classes of tests in the following order: First, the identity tests, for it is apparent that if the substance fails to meet the requirements in this respect it is unnecessary to apply additional tests; second, the test for strength, for here again, if the substance is found to be substandard, that is, below standard, the article may be rejected without proceeding further; lastly, the tests for small amounts of impurities which would have no influence upon tests for identity or strength. For a very complete study of the rationale of the U. S. P. and N. F. chemical tests, see page 1449.

Assuming that the pharmacist has undertaken analytical work, along the lines previously outlined, for the examination of his own products, his ambition may next be properly directed to the classes of work for which opportunity exists in nearly every community, in which specialized service may be given to the medical profession, including boards of health, to the legal authorities, to such industries as are not equipped for doing their own laboratory or control work, or to the laity in the examination of water and food samples.

The first of these possibilities is covered in the chapter on Diagnostic and Clinical tests (see page 1568). The others may be developed as need or opportunity arises in the particular community in which the pharmacist happens to be situated. Work for the legal profession comprises a number of possibilities, such as the determination of alcoholic strength of liquors, tests for the identification or detection of narcotic drugs and many others along similar lines.

Industrial work is very broad in its scope, but the pharmacist's technical knowledge of chemicals and of the principles underlying manufacturing operations gives him an advantage which can frequently be utilized in the solution of minor manufacturing problems. Work upon food products includes such determinations as the quality of milk and its freedom from preservatives; the testing of butter for moisture content or its distinction from oleomargarine; the testing of beverages for the presence of saccharin, preservatives, or the presence of forbidden colors; sanitary chemical water analysis, etc.

FIG. 510



Laboratory cabinet

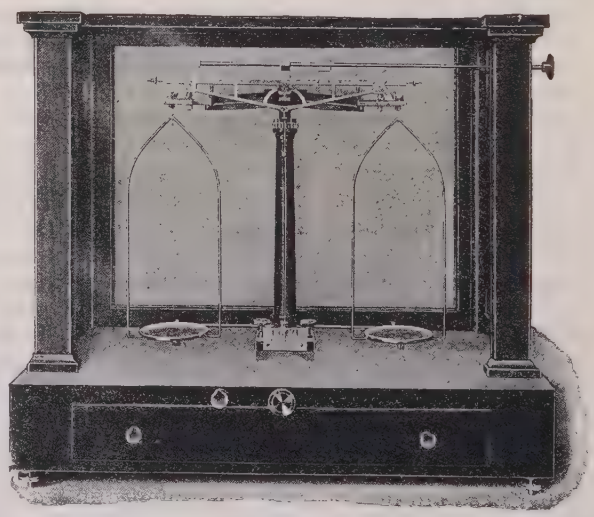
For all such work the pharmacist should charge the standard or prevailing price for conscientious, careful service. Price lists for analytical determinations are obtainable upon application to established laboratories or information may be obtained therefrom concerning charges for specific kinds of work.

If the amount of work increases so as to justify expenditure for additional apparatus and equipment, the first effort should be directed toward the purchase of an analytical balance and the installation of a laboratory work counter (see Fig. 510).

There are many firms supplying laboratory fixtures from whom catalogues and prices may be obtained upon application.

An analytical balance differs from a high class prescription balance in the matter of sensitiveness; a satisfactory analytical balance is sensitive to the tenth of a milligram (approximately 1/600 grain), and should never be used for weighing more than 100 Gm. at one time.

FIG. 511



Troemner analytical balance

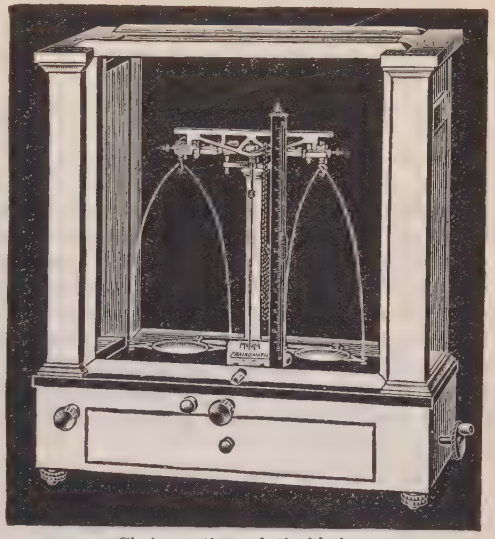
Modern analytical balances are constructed with extraordinary care and accuracy. They are always provided with leveling devices, and with levers for arresting the motion of the balance so as to expedite weighing. The beam of an analytical balance is graduated (sometimes on both sides of the center of gravity) and equipped with a platinum wire rider, which is manipulated by a sliding adjustable lever. The fractions of a milligram are weighed by means of this rider, which may be quickly transferred to any portion of the beam. Henry Troemner and Company, of Philadelphia, list an excellent analytical balance (see Fig. 511).

Another type of analytical balance is the Chainomatic balance (see Fig.

512) in which fractional weights are recorded by means of an adjustable swinging chain, and individual weights under 1 Gm. may thus be dispensed with entirely. It is manufactured by the Christian Becker Company.

A set of accurate high class analytical weights is needed in connection with the use of the analytical balance. These should never be left uncovered when not in use and the individual weights should always be handled with the tweezers accompanying the set (see Fig. 513).

Fig. 512

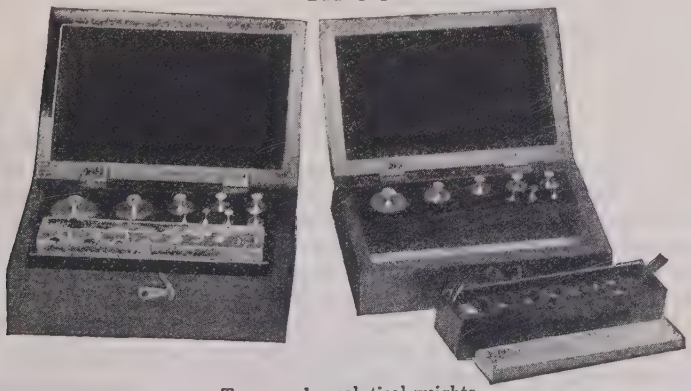


Chainomatic analytical balance

The works of reference needed in an analytical laboratory depend entirely upon the scope of work. For pharmaceutical testing of official substances, the U. S. P. and N. F. of course are given primary consideration. Among the indispensable adjuncts of the analyst's library are the following works:

Official Methods of Analysis of the A. O. A. C.—covering foods, beverages insecticides, fertilizers, drugs, etc.
Standard Methods of Chemical Analysis, Scott.
Food Inspection and Analysis, Leach.
Allen's Commercial Organic Analysis.
Detection of Poisons, Autenrieth translated by Warren.
Standard Methods of Water Analysis, A. P. H. A.
Standard Methods of Milk Analysis, A. P. H. A.
Volumetric Analysis, Sutton.
Chemical Technology of Oils, Fats, and Waxes, Lewkowitsch.
Analysis of Drugs and Medicines, Nelson.
Chemistry and Analysis of Drugs and Medicines, Fuller.
Micro-Chemical Tests for Alkaloids, Stephenson.

Fig. 513



Troemner's analytical weights

Many valuable publications may be obtained from the various departments of the United States Government. The departments whose publications are of particular value to the analyst are those of the U. S. Department of Agriculture, Bureau of Chemistry, and those of the Bureau of Standards.

Upon application to the Superintendent of Documents, Washington, D. C., lists of publications covering particular fields of work may be obtained free of charge, and from these may be selected the publications which are desired, usually for a nominal price ranging from 5 cents to 25 cents per copy, and in this manner a very complete reference library may be acquired at a comparatively small cost.

Among the more valuable of these Government publications from the standpoint of information, are those issued by the U. S. Department of Agriculture, which give the standards of purity to which various food products must conform.

The publications of the American Medical Association are particularly helpful in connection with the examination of non-official pharmaceutical preparations. The laboratory Reports of the Council of Pharmacy and Chemistry of the A. M. A. contain detailed descriptions of many specially devised methods of analysis and the book entitled Nostrums and Quackery contains valuable information concerning the composition of many proprietary remedies.

It is in problems connected with the composition of medicinal preparations more than in any other class of substances that the limitations of chemical analysis are appreciated. There are many drugs which contain no constituents capable of accurate estimation or even of certain identification. In such cases an experienced pharmacist may make use of his training in connection with the physical properties of drugs and their preparations in arriving at a knowledge of the ingredients which contribute the predominant physical characteristics of the preparation.

Important factors in the successful practice of analytical chemistry are the proper selection and adaptation of methods of analysis for substances other than those which are official or for which methods are not available in the works of reference at hand, and also in the intelligent interpretation of results and in the formulation of reports which may be easily understood by the persons for whom they are intended.

An individual may be an excellent analyst in connection with routine work, but if he possesses no resourcefulness in emergencies, or if he cannot intelligently interpret his results to the satisfaction of himself or of his client, or if he cannot write a final report which is intelligible to the recipient, he will fail just as certainly as though his work itself were faulty.

The pharmacist who possesses the ability and the inclination and can find the time to devote a minimum of a few hours a week to the simpler analytical procedures will find himself repaid in many ways. He will acquire a first hand knowledge of the quality, purity, and strength of some of his official preparations and in so doing will gain confidence in himself, his work and in his profession, in the larger sense. He will acquire a facility in manipulative detail that will stimulate his ambition to go further, and the further he goes the more fascinating and profitable he will find the work. It is fascinating in that it unfolds new vistas of professional interest and activity, and profitable not only in insuring him against the possibility of being penalized as a violator of the pharmacy laws in regard to the strength and purity of the medicines dispensed by him, but also profitable in affording time and opportunity to develop a remunerative class of work for which opportunity exists in nearly every community.

CHAPTER LXXXVI

URINALYSIS

THE fact that neighborhood physicians are relying more and more upon the local pharmacist to perform the simpler diagnostic tests, and especially urinalysis, prompts the compilation of this special chapter. Moreover, it is quite apparent that there is a desire among pharmacists to develop professionally along lines of service, such as are presented in association with the physician in the performance of these special tests and examinations. With the specialized chemical training which is now a part of the pharmacist's professional education, he is well fitted to perform this type of service. His technical information, his skill in manipulation, and his experience in accurate weighing and measuring are all contributory to his special fitness to conduct these important diagnostic tests.

One who can be trusted to weigh with exquisite accuracy the tiny particle of aconitine, that may mean life or death to the person for whom it is intended, is expected to be equally careful and as conscientious in performing even the most insignificant test of physiologic function.

Medical information has awakened the laity to the need for watchfulness over the body even in times when health may seem dominant. The insurance companies and health agencies are continually preaching preventive medicine. The individual has been taught the value of the blood and the urine test, and no longer will the cursory test of the old family doctor suffice. It must be performed by a specialist, and the physician frequently turns over to the patient the results of the analysis.

EXAMINED BY

Model urinalysis report

Thus has the scope and the work of the clinical laboratory been broadened and enlarged. Thus has an opportunity to serve come to the pharmacist. These facts fully justify the introduction of a special chapter on urinalysis into this work.

In reporting the results of clinical examinations, in justice to both the physician and the patient, it is always necessary to render reports directly to the physician. Only when definitely instructed to do so by the physician, should the analyst report his findings verbally or otherwise to the patient. He should never attempt a diagnosis or discuss the clinical findings with the patient.

A printed or mimeographed report blank may be compiled to suit the needs of the analyst, but a better plan is to formulate it to suit the wishes of

the physician who reads it. Such a report, filled in for a typical analysis, is submitted herewith, and will serve as a pattern (see Fig. 514).

To facilitate the collection of specimens, mailing bottles, bearing a label (see Fig. 515), should be supplied to physicians of the neighborhood. In the clean bottle should be placed a few drops of saturated boric acid solution as a preservative. This policy is an aid to the development of this type of professional work.

The instruments and apparatus required to conduct a small clinical laboratory need be neither elaborate nor expensive. However, in addition to ordinary glassware, and the regular equipment of the pharmacy, the following equipment will be found necessary for a full examination.

Fig. 515

will insure a prompt report.

The Report is always Mailed Directly to the Physician.

Label for urine sample

A well-equipped microscope provided with high and low power, and oil-immersion lenses such as the Spencer microscope (see Fig. 516).

A centrifuge (hand, water, or electrically driven).

The extra glassware consists of a burette, pipettes, urinometers, ureometer, albuminometer, etc.

The following textbooks are suggested as authoritative and practical, giving not only a broader treatment of urinalysis, than is possible here, but also containing chapters on gastric analysis, blood analysis, sputum examination, and many other subjects which may be readily added to the general work of a pharmaceutical clinical laboratory. The first is the more generally useful: *Clinical Diagnosis*, Todd; *Practical Physiological Chemistry*, Hawk; *U. S. Army Laboratory Manual, No. 6*, and *Blood and Urine Chemistry*, Gradwohl and Blaivas.

It is obvious that beyond the conduct of certain of the ordinary tests, such as blood counting, urinalysis, gastric content analysis, etc., special training is required, as for instance, in conducting the Wassermann test, or other complement fixation tests. But with a keen interest in this work, and the training already attained, no one is better fitted to perform even the more complicated tests than the graduate in pharmacy. Certainly the physician can better trust his work to the well-trained pharmacist than to a technician whose only scientific training is that acquired in a hasty three or six months' intensive course, where fundamentals are brushed aside and only the technical operations perfected.

Composition of Urine

The composition of urine is very complex, as indicated in the following table. It is to be noted that there may be, even in a normal urine, great variances from the figures given in this table. It may be accepted, however, that the average healthy person, under average conditions, will secrete urine of about this composition. The normal twenty-four hour excretion of urine measures from 1000 cc. to 1500 cc. consisting of:

NORMAL CONSTITUENTS

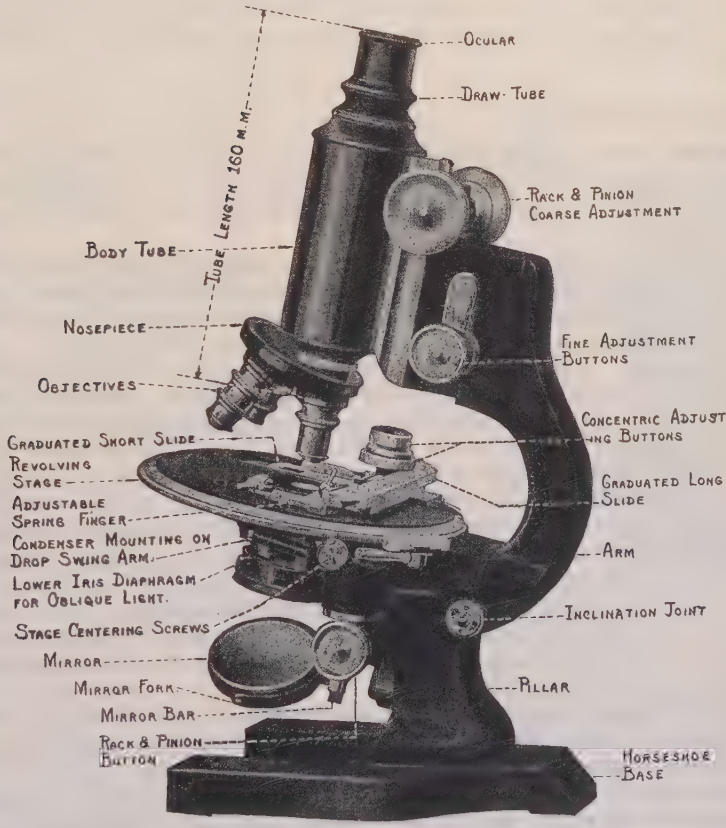
Water	1000 to 1500 cc.
Dissolved Solids	50 to 60 Gm.

The dissolved solids consist of the following:

Urea	30 to 40 Gm.
Chlorides	15 Gm.
Sulphates	2.5 Gm.
Phosphates	2.5 Gm.
Ammonia	0.7 Gm.
Uric Acid	0.7 Gm.

Other substances such as pigment, creatinin, hippuric acid, etc.

FIG. 516



Spencer microscope

The following list comprises those substances which are considered abnormal when found in urine in appreciable amounts.

ABNORMAL CONSTITUENTS

Proteins: Serum albumin, serum globulin, albumoses, mucin, Bence-Jones protein.
Carbohydrates: Glucose, lactose, pentose, levulose and other sugars.
Acetone bodies: Acetone, aceto-acetic acid (diacetic acid) and oxy-butyric acid.
Bile.
Indican.

The abnormal microscopic factors are considered elsewhere in the text.

Examination of Urine

A twenty-four hour specimen is usually desirable, because the total excretion of both solids and water can be learned in this way. A single specimen is sometimes useful, as sugar or albumin may be present in the urine at one time of the day and not at other times.

Generally no preservative is needed. When, however, the urine must be carried a long distance or kept more than a day or two a preservative is required. Solution of formaldehyde (formalin) may reduce copper solutions used in sugar tests, and should not be added. Thymol vitiates certain tests and so does salicylic acid. This prohibits their use as urine preservatives. Boric acid, in very small amount (about 0.5 Gm. per sample), is the most effective preservative.

PHYSICAL PROPERTIES

Amount—The normal quantity for an adult is from 1000 to 1500 cc. in twenty-four hours. Children pass more in proportion to body weight than adults. A new-born infant passes from 150 to 200 cc., a child of five years about 700 cc.

In health more urine is passed during the day than during the night. This may be reversed in disease, notably in chronic interstitial nephritis.

The amount varies physiologically according to the quantity of fluids and watery foods taken and the activity of other organs of elimination.

Appearance—Normal urine is transparent, though a slight cloud of mucus may appear on standing. Cloudiness is generally due to pus, blood, bacteria, urates, or phosphates. Albumin itself, in pathologic amounts, causes no change in the appearance of the urine, except that it may, in unusual amount, increase the viscosity to a perceptible degree. The consistency of normal urine is watery; pathologically it may be frothy from the presence of albumin, syrupy from the presence of sugar, or ropy from mucus or pus in alkaline urine.

Odor—Normal urine has a faint aromatic odor. On standing a long time all urines are decomposed (undergo alkaline fermentation) and have a very unpleasant odor. Certain drugs (cubeb, copaiba, tolu, saffron, and turpentine) impart specific odors to urine. Asparagus promptly imparts a very characteristic odor to urine. A pus-containing specimen often develops a putrid odor on standing, due to bacteria.

Color—Normal urine is amber or straw colored. It may vary a great deal within normal limits. With the ingestion of certain drugs and in some diseases, the color may be any of the following:

Blue or green. The administration of methylene blue usually accounts for a blue or greenish color. On rare occasions a bluish urine appears from putrefactive changes in the intestines in cholera.

Dark yellow or greenish-brown. This color is usually due to bile. A vivid yellow often appears in the urine of persons habituated to phenolphthalein. This is indicated by its turning red when rendered alkaline.

Black. Melanin from a melanotic sarcoma may color the urine black. In salol, phenol, or iodoform poisoning, the urine may turn black on standing. Silver compounds (such as argyrol, protargol, etc.), used for irrigating, frequently color the urine a deep brown, especially the sediment formed on standing.

Red, brown, or smoky color. This may be due to blood.

Red. In an alkaline urine this may be due to phenolphthalein, rhubarb, senna, or cascara (or any emodin-bearing drug).

White. A milky appearance is found when there is an admixture of chyle.

Reaction—Normal urine is usually acid in reaction, but may be temporarily neutral or alkaline. An amphoteric reaction, the urine turning red litmus paper blue and blue litmus paper red, is not unusual and has no pathological significance. Alkaline urine may be due to decomposition in the bladder as in cystitis with retention of the urine, or to administration of alkaline drugs. A meat diet has the tendency to increase the acidity, and a fruit and vegetable diets to diminish acidity. Thus a change in reaction may be from a pronounced acid to a pronounced alkaline, in a normal person, during the course of a day.

The reaction is determined by the use of litmus paper, acid urine turning blue litmus paper red, and an alkaline urine turning red litmus paper blue.

Total Acidity—The total acidity of urine varies considerably. In estimating the total acidity, the specimen of urine should be a mixture of the twenty-four hour excretion, and should be as fresh as possible.

It may be quantitatively determined in the following manner:

Folin's Method of Estimating Acidity—Measure 10 cc. of urine into a 100 cc. flask, add about 25 cc. of distilled water, 3 drops of a 1 per cent alcoholic solution of phenolphthalein and about 2 Gm. of potassium oxalate. Add slowly N/10 NaOH until a permanent faint pink color appears. The flask should be shaken after each addition of alkali, and the alkali added drop by drop after adding the first one or two cc. The number of cc. of N/10 NaOH required to neutralize 1 cc. of urine, multiplied by the number of cc. of urine passed in twenty-four hours, gives the degree of total acidity.

Fig. 517

Urinometer

Specific Gravity—The normal specific gravity of a twenty-four hour specimen of urine is between 1.012 and 1.020. Normally a great variation occurs in separate passages of urine, the night urine having a higher specific gravity. It also varies normally according to the amount of fluid ingested, and the quantity of skin excretion.

Physiologically, the specific gravity varies inversely as to the quantity. It is increased by nitrogenous diet. Pathologically, the specific gravity is high in the following diseases: diabetes mellitus, acute nephritis, acute fevers. The specific gravity is low in diabetes insipidus, and in chronic interstitial nephritis the specific gravity is markedly fixed and low, due to inability of the kidney to excrete a concentrated urine.

The specific gravity is estimated by means of the urinometer (See Fig. 517, and page 63). This is sufficiently accurate for general clinical purposes. The instrument is generally calibrated for use at 15° C. If the specific gravity is taken at any other temperature, correction as given below must be made. In making this correction, one unit in the third decimal place is added for every three degrees above 15° C., and subtracted for every three degrees below 15° C.

Example: The urinometer is calibrated for 15° C.
The specific gravity of the urine when taken at 18° C. is 1.020.
The true specific gravity at 15° C. would be 1.020 plus 0.001 = 1.021.

In using the urinometer always read the meniscus at the lowest point.

Total Solids—By the total solids is meant the solids excreted in twenty-four hours. The chief value of the estimation of the specific gravity is to give an idea of the amount of solids excreted. The normal total solids of an adult on ordinary diet is about 60 Gm. About 4 per cent of the weight of the urine is that of the solids and of this, urea forms a little less than half.

The total solids may be estimated by the use of Haeser's coefficient. The two last figures of the specific gravity multiplied by 2.33 (Haeser's coefficient) equals the Gm. per 1000 cc. This multiplied by the number of liters (1000 cc.) passed in twenty-four hours gives the total solids. Example: 1400 cc. of urine is the twenty-four hour amount. The specific gravity is 1.016. 16 x 2.33 x 1.4 = 52.19. The total solids are 52.19 Gm.

Long's coefficient (2.6) is used in much the same way, and is considered more accurate by many authorities.

CHEMICAL CONSTITUENTS

Albumin—In the classification of organic substances albumin is in the group of proteids, hence is often referred to as such. The presence of albumin in the urine is spoken of as albuminuria, and when present in appreciable amount is considered an indication of an abnormal condition. True albuminuria is the presence in the urine of albumin which has escaped through the cortex of the kidney. There is, however, an albuminuria without definite kidney lesions (usually small amounts of albumin). This may be functional, as after severe exercises, or after prolonged cold baths. Contaminating bacteria in a stale urine will afford a false albumin test.

A wrong impression is prevalent in some quarters that when albumin is found by chemical test in urine, there will *always* be found microscopically such findings as casts, blood, or pus cells. The converse is more nearly true, *i.e.*, albumin will be found always when casts, blood or pus cells are present —but albumin may be found in the absence of these.

Serum albumin and serum globulin are usually both present in albuminuria, sometimes also nucleo-albumin and albumoses. Most ordinary tests respond to all these substances. The appearance of proteoses or globulin, except in association with serum albumin, is rare. The Bence-Jones proteid appears in the urine in multiple myeloma. When present, there is usually a large amount. This proteid coagulates on heating at about 60° C., clears up on further heating, and reappears on cooling.

For all albumin tests the urine must be clear. If cloudy, filter. If still cloudy, mix the urine with light magnesia or purified siliceous earth (kieselguhr), and filter.

Qualitative Tests for Albumin: Heller's Test—Take an inch of urine in a test tube. Carefully underlay this with half an inch of strong nitric acid. Should the urine be alkaline, it is best to acidulate it with a few drops of acetic acid before conducting the test.

Interpretation of the test:

Precipitates.

Albumin shows a white ring at the junction of the acid and urine.

Nucleo-albumin or *mucin* shows a white ring above the contact with a clear zone between.

Urates show a cloud above the contact line which disappears on heating or on using diluted urine.

Colors.

Normal—varies from a faint pink to a brownish ring at the point of contact.

Biliary pigment—dark green or blue.

Indican—violet or bluish when great excess is present.

Iodides—intense brownish red.

Aniline-compounds—red to purple.

Robert's Modification of Heller's Test—Use in place of the nitric acid a reagent consisting of 100 cc. of a saturated aqueous solution of magnesium sulphate mixed with 20 cc. of nitric acid.

The interpretation is the same as that of Heller's test so far as the precipitates are concerned, and the test is more delicate, particularly in that the colored rings are not so much in evidence.

Coagulation Test—Heat about 15 cc. of urine in a test tube, boiling it near the surface of the fluid. The addition of a few drops of acetic acid to the liquid will show a persistent cloudiness if albumin is present. Phosphates will be precipitated by the simple heating, but this precipitate will promptly dissolve in the acid. Often in an intense albuminuria, as in eclampsia, the urine "boils solid" (*i.e.*, coagulates). This is an indication of the presence of between two and four per cent of albumin. Many authorities prefer this method, as it is simpler than the other tests.

Quantitative Estimation of Albumin: Purdy's Method—Into a 15 cc. graduated, conical centrifuge tube place 10 cc. of clear urine, 3 cc. of a 10 per cent potassium ferrocyanide solution, and 2 cc. of 50 per cent acetic acid. Shake the tube, set it aside for ten minutes to allow for the precipitation of the albumin, centrifuge for exactly three minutes at 1500 revolutions per minute, in an instrument with a radius, including the tubes, of exactly 6¾ inches. Then remove the tube from the centrifuge and determine the number of Gm. of albumin per liter by the following table. If the amount of albumin is very large, the urine should be accurately diluted.

Relation of Precipitate to Albumin per 1000 cc.

Volume of precipitate in centrifuge tube	Weight of dry albumin per 1000 cc.	Volume of precipitate in centrifuge tube	Weight of dry albumin per 1000 cc.
0.25	0.5	2.75	5.7
0.5	1.0	3.0	6.3
0.75	1.6	3.25	6.8
1.0	2.1	3.50	7.3
1.25	2.6	3.75	7.8
1.5	3.1	4.0	8.3
1.75	3.6	4.25	8.9
2.0	4.2	4.50	9.4
2.25	4.7	4.75	9.9
2.5	5.2	5.0	10.4

Example: The centrifuged precipitate is 1.5 cc. before testing, which, by the use of the table, is found to equal 3.1 Gm. of albumin per 1000 cc. The twenty-four hour specimen contained 1500 cc.; multiplying 3.1 by 1.5, the result equals 4.65 Gm. of albumin in 1500 cc.

Tsuchyia's Method—(For use where no centrifuge is available).[1]

[1] Descriptions and formulas of the reagents and test solutions specified in this chapter will be found in the chapter on Reagents.

To conduct the test, fill an albuminometer (see Fig. 518) to the letter U with clear, filtered urine. Add the reagent, filling the tube to the mark R. Insert a rubber stopper and invert several times until the contents are thoroughly mixed. Carefully remove the stopper to allow the escape of generated vapors, again stopper the tube and set it aside for twenty-four hours.

Fig. 518

Albuminometer

In from twelve to eighteen hours examine the liquid in the tube, and if the precipitate tends to adhere to the sides of the albuminometer, rotate once very gently between the palms of the hands. If done properly, this will loosen the flocculi and cause them to fall to the bottom of the tube.

This procedure must be done very gently, otherwise the sediment already formed will be disturbed. At the end of twenty-four hours, read the height of the precipitate in the albuminometer and calculate the parts of albumin, by weight, from the following table, bearing in mind that the parts must be multiplied by the dilution, if it has been found necessary to dilute the urine with water. The final result will be the Gm. of dry albumin per 1000 cc. of the sample.

Example: If the precipitate is level with the 2 cc. mark, Pfeiffer's table shows that there are 3.2 parts per thousand or 0.32 per cent. of albumin.

Relation of Precipitate to Albumin per 1000 cc.

0.5 cc.	= 1.00 parts per 1000
1.0 cc.	= 1.50 parts per 1000
1.2 cc.	= 1.75 parts per 1000
1.4 cc.	= 2.00 parts per 1000
1.6 cc.	= 2.40 parts per 1000
1.8 cc.	= 2.80 parts per 1000
2.0 cc.	= 3.20 parts per 1000
2.2 cc.	= 3.60 parts per 1000
2.4 cc.	= 4.00 parts per 1000

Glucose (Dextrose)—Glucose or dextrose (grape sugar) ($C_6H_{12}O_6$) is the only important carbohydrate found in urine. The presence of glucose in the urine temporarily does not mean the existence of diabetes any more than does the presence of albumin always indicate nephritis. After a diet rich in carbohydrates glucose may appear in the urine temporarily and such a condition is spoken of as physiological or alimentary glycosuria.

However, when glucose is persistently present in appreciable quantity, *diabetes mellitus* is indicated. Large amounts of glucose have been found in this disease, from 150 to 250 Gm. (5 to 8 oz.), per diem being the average; a urine containing more than 10 per cent of glucose is seldom excreted. The sugar in urine is not identical with table sugar (sucrose). It is different in chemical composition and in chemical behavior. For instance, table sugar does not directly reduce Fehling's solution.

Qualitative Test for Glucose—Benedict's solution is now considered more accurate than either Fehling's or Haines' solution, and it has the additional advantage of permanence. For qualitative work there are many, however, who consider Fehling's solution superior to any other. Under no circumstances should the Benedict's qualitative reagent be confused with the Benedict's quantitative reagent.

Place about 5 cc. of Benedict's qualitative solution in a test tube, add from 8 to 10 drops (not more) of the urine under examination, and boil the mixture

vigorously for a minute and a half and allow it to cool spontaneously. In the presence of sugar (glucose), the entire solution will be filled with a precipitate, which may be red, yellow, or green, depending upon the amount of sugar present.

If the amount of glucose is small (under 0.3 per cent), the precipitate forms only on cooling. If the urine contains no sugar (glucose), the solution either remains perfectly clear, or shows a faint blue turbidity consisting of precipitated urates, which should cause no confusion. Even very small quantities of glucose (0.1 per cent) yield precipitates of surprising bulk with Benedict's reagent.

Lactose (milk sugar) is occasionally found in the urine of expectant or nursing mothers. It is a reducing sugar, *i. e.*, it will behave chemically like glucose. There are special tests which may be used to distinguish it from glucose. Unlike glucose it is not readily fermentable.

Benedict's Quantitative Estimation of Glucose—The titration method of Benedict is now conceded to be far superior to the older titration methods of Fehling and Purdy. This method gives excellent results and no special or expensive apparatus is required. It is superior to the Lohnstein fermentation test, because the results may be obtained at once (in about five minutes). It is also superior to the polariscope method in those instances when lævorotatory substances (as β-hydroxybutyric acid) are present, thus necessitating a determination both before and after fermentation.

Place the urine in a graduated burette, pipette 25 cc. of Benedict's volumetric solution into a non-soluble glass flask of about 150 cc. capacity and add from 5 to 10 Gm. of anhydrous sodium carbonate and a small amount of powdered pumice.

Heat the mixture to boiling on a piece of wire gauze, with an asbestos center and run the urine in rapidly from the burette until a chalky-white precipitate begins to form. Then run the urine in more slowly, with continuous boiling, until the last trace of blue color disappears, indicating the end point. Chloroform or formaldehyde, if present, should first be removed by boiling, as they interfere with the reaction. Benedict found that 0.050 Gm. of glucose or 0.052 Gm. of levulose reduced 25 cc. of Benedict's volumetric solution. Myers and Fine found that 0.054 Gm. of galactose or 0.067 Gm. of lactose reduced 25 cc. of this volumetric solution. If a large amount of glucose is present, the urine should be accurately diluted and the test carried out on the diluted specimen, the final results being multiplied by the proper factor.

Example: A twenty-four hour specimen of urine contained 2500 cc. The quantity of urine required to reduce the 25 cc. of Benedict's (equivalent to 0.050 Gm. of Glucose) was 12.5 cc.

Therefore—12.5 cc. of urine contains 0.050 Gm. of glucose;
1 cc. of urine contains 0.004 Gm. of glucose;
2500 cc. of urine contains 10 Gm. of glucose;
2500 cc. contains 10 Gm. (24 hour output)
100 cc. contains $\frac{10}{25}$ or 0.4 per cent of glucose.

Urea—Urea is the chief organic constituent and the most important nitrogenous end product in urine. Half of the protein nitrogen taken into the system as food is excreted by the kidneys as urea. Thus the detection of urea may be utilized as a means of identifying an unknown liquid suspected of containing urine.

The percentage of urea in normal urine varies largely with diet and with urine concentration. The average normal quantity is between 2 and 2.5 per cent. In disease the amount retained in the blood varies greatly. A test conducted on a single sample of urine is of no value. It should be conducted only on an aliquot portion of a twenty-four hour specimen. Obviously the test is always quantitative. It is conducted with solution of sodium hypobromite and the instrument illustrated in Fig. 519 known as the Doremus-Hinds' ureometer. This instrument on the indicating arm reads to a total of 0.03 Gm. of urea per cc. in 0.001 Gm. graduations. The small urine arm reads to a total of 2 cc. of urine in 0.1 cc. graduations.

Conduct of the Test—Take 5 cc. each of solutions *one* and *two* (see Solution of Sodium Hypobromite, page 1570) in a large test tube, mix, and dilute with 10 cc. of distilled water. Before pouring this solution into the ureometer close the stopcock. Fill the bulb with the reagent just prepared and incline the tube until the long arm is completely filled and sufficient liquid remains in the open tube to prevent any bubbles of air forming at the top of the closed arm. Should 20 cc. be insufficient, a few cc. of distilled water may be added. The small arm is filled exactly to the zero mark with urine to be tested.

FIG. 519

Ureometer

Carefully turn the stopcock, allowing 1 cc. of urine to enter the tube containing the reagent. This should be done very slowly. As soon as the evolution of gases (chiefly nitrogen) has ceased, usually in from ten to twenty minutes, read off the number of cc. of gas in the long arm, and multiply this figure by 1000 to obtain the amount of urea, which is expressed in Gm. per 1000 cc. of urine.

Theoretically, in using the ureometer the urine should be free from both albumin and sugar. Practically, however, these substances need not be removed. For all clinical purposes this method is entirely sufficient and no other is required, although the Urease Method is considered more accurate.

Indican—Indican (indoxyl-potassium-sulphonate) is formed from indoxyl, an oxidation product of the intestinal putrefaction of albuminous substances.

Indican in a small amount is a constituent of normal urine. Constipation generally is considered a frequent cause of indicanuria.

This substance is tested for by a method whereby the indican is oxidized to indigo blue, which color is soluble in chloroform. The reagent used to oxidize is Obermeyer's solution, which is a solution of 0.4 per cent of ferric chloride in hydrochloric acid (4 parts per 1000). This reagent keeps indefinitely.

Fill a test tube one-quarter full of the reagent, and add an equal amount of the urine to be tested, followed by a small quantity of chloroform. Cover the tube with the thumb and invert it several times slowly without shaking. The chloroform becomes blue in proportion to the indican present, the color increasing on standing. An accurate reading can usually be made in from five to ten minutes. With normal urine a faint blue color will result, while an increase of indican gives a deep blue color.

If the urine is originally highly colored, decolorize with a small amount of lead acetate solution, and filter, as its pigments may interfere with the recognition of the blue color. Color observations should be made only after a lapse of a definite time and for purposes of comparison this time should not vary as the color darkens on standing.

Patients taking iodine will show a false reaction with the chloroform, which,

in the presence of iodine, is colored violet and not blue as with the indican. A confirmatory test may be made, identifying the iodine by its characteristic reaction with starch.

Bile—Bile in the urine is always pathological. It appears whenever bile is present in the blood, that is, in jaundice from any cause. Bile may appear in the urine before the jaundice is apparent in the skin. Bile salts and bile pigments usually appear together and tests for bile pigments usually suffice for both. A greenish-yellow urine, which when shaken shows a persistent yellow froth, is typical of bile.

Tests—*Gmelin's Test*—Superimpose the urine upon nitric acid in a test tube. If bile is present, a dark green color will appear at the point of contact.

Smith-Rosen Test—Superimpose 2 cc. of Smith's reagent, which is a 1 per cent alcoholic solution of iodine, upon about 10 cc. of urine in a test tube: an emerald green ring appearing at the point of contact indicates bile.

β-Oxybutyric Acid, and Acetone, and Diacetic Acid—These so-called ketone bodies are mostly found in acid urines and are indications of simple or complicated acidosis. Frequently they are present in diabetic urines, and when so found are considered gravely significant. They represent the failure of the diabetic patient to completely oxidize the fats. These ketone bodies, end products of incompletely consumed fats, appear in excess in the blood, and are transferred to the kidneys for excretion. Fasting, anesthesia, etc., produce a temporary acidosis, with its acetonuric signs.

Diacetic Acid—*Gerhardt's Test*—To about 5 cc. of urine add solution of ferric chloride, drop by drop, until no more precipitate forms. If diacetic acid is present, a violet-red or Bordeaux-red is produced. A variety of drugs or their derivatives, notably the salicylates, give a positive reaction when present in urine, so that a positive result only indicates the possible presence of diacetic acid. If confusion due to drugs is suspected, boil the red solution from two to three minutes; if the color is due to diacetic acid, it should disappear during boiling, and not reappear on cooling. Still better, as a confirmatory test for the presence of interfering substances, boil the urine and cool before the reagent is added: the diacetic acid will be driven off, but salicylates are fixed, and when the reagent is added, the color will be apparent.

Acetone—As with diacetic acid, this test must not be applied to heated urine, because of its volatility.

Lange's Test—To 5 cc. of urine, add a few drops of a freshly prepared saturated solution of sodium nitroprusside and then 5 cc. of a 20 per cent solution of sodium hydroxide. At this state, acetone will indicate its presence by a permanent crimson color. However, to confirm its presence, add a few cc. of glacial acetic acid to the well-shaken mixture: a purple color indicates acetone.

A test using more easily available reagents is the following:

Half fill a test tube with urine and add 1 cc. each of an aqueous solution of iodine and ammonia water: a black precipitate of nitrogen iodide forms and gradually disappears. If acetone is present, iodoform is formed, and is recognized by its odor, yellow color, and the microscopic appearance of its crystals, which are hexagonal plates. It should be noted, however, that ethanol (ethyl alcohol) in urine will produce the same reaction.

Chlorides—Occasionally a request is made for a quantitative determination of the chlorides in urine. Normally the chloride excretion is about 15 Gm. per day.

Modified Volhard Method—Pipette 5 cc. of urine into a small dish and add about 20 cc. of distilled water. Precipitate the chlorides by the addition of exactly 10 cc. of the standard silver nitrate solution (indicated below) and

add 2 cc. of ferric ammonium sulphate T.S. Add from a burette standard ammonium thiocyanate solution (indicated below) until the first trace of yellow shows throughout the mixture on stirring. By subtracting the number of cc. of ammonium thiocyanate solution required to exactly precipitate the chloride from ten (the amount of silver nitrate solution added), and multiplying by 0.01, the number of Gm. of sodium chloride in 5 cc. of urine will be obtained. From this the total chloride excretion for the twenty-four hour specimen may be computed.

Example: Suppose a twenty-four hour urine specimen measured 1500 cc. It required 6.2 cc. of the ammonium thiocyanate solution and this, subtracted from ten, the amount of silver nitrate solution taken, indicates 3.8 cc. of the silver nitrate solution to precipitate the chlorides present. Multiply this by 0.01 Gm. (1 cc. of the standard silver nitrate equals 0.01 Gm. of sodium chloride); the result shows 0.038 Gm. of sodium chloride in 5 cc. of the urine. In 1500 cc. of urine there will then be 300 times 0.038 Gm. of sodium chloride, or 11.4 Gm. of sodium chloride in the 1500 cc. of urine.

The standard test solutions required for the above test are as follows:

Standard Silver Nitrate Solution—Dissolve 29.06 Gm. of silver nitrate in distilled water and make up to 1000 cc. with distilled water. Each cc. of such a solution is equivalent to 0.01 Gm. of sodium chloride.

Indicator—Dissolve 100 Gm. of crystalline ferric ammonium sulphate in 100 cc. of 25 per cent nitric acid.

Standard Ammonium Thiocyanate Solution—Dissolve about 13 Gm. of ammonium thiocyanate in 800 cc. of distilled water. Titrate this solution against the standard silver nitrate solution, and adjust its volume by adding distilled water, so that it is exactly equivalent to the silver nitrate solution.

MICROSCOPIC EXAMINATION

The microscopic examination of urinary sediments requires considerable practice and a keen sense of visual appreciation. The novice and the careless frequently report the presence of urinary sediments of blood, when blunted calcium oxalate crystals or small white cells are really present; or he may report casts simulated by odd shaped epithelia or all manner of odd foreign matter which may be accidentally present. The novice in urinalysis frequently insists on finding pathologic factors when none are present. In the search for significant criteria in the clinical laboratory, the technician must be ever on guard against pre-formed judgments, and against bias and undue imaginings. The safe dictum in the laboratory always is:

"Report exactly what is found—not a whit more—not a whit less."

The value of the microscopic examination of the urine is of exceeding importance from a diagnostic point of view, often more so than the chemical examination. To determine the nature of the insoluble constituents of the urine it is necessary to find a way of collecting these into a sediment which can then be examined microscopically. This can be accomplished by allowing the urine to settle in a conical glass or, much more expeditiously, by centrifuging. This is done by pouring the urine into a conical tube and whirling in the centrifuge (see page 229) at a fair speed for a few minutes. At the end of this time, take the tube out of the centrifuge and introduce a pipette into the bottom of the tube, a finger being placed over the upper opening of the pipette so as not to allow any urine to enter the pipette while it is being lowered to the bottom of the tube. When the pipette touches the bottom, remove the finger and the deposit will flow into the pipette. Again close the upper end of the pipette,

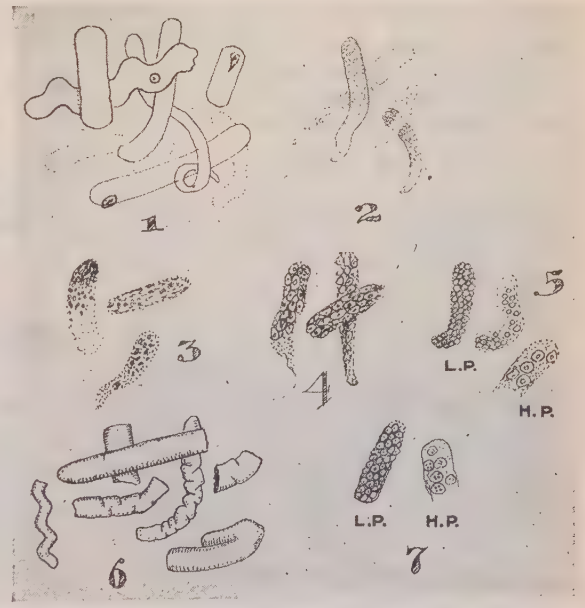
withdraw it, place a drop of the sediment on a clean microscopic slide and place a cover glass over the sediment. It is well to examine the sediment first under the low power of the microscope, care being taken that much of the light is shut off. Casts are not easily seen in the presence of much illumination. Then examine the sediment under the high power, using a dry lens. In this way any suspicious elements noted under the low power may be clearly seen under the high power. When the urine is to be examined for bacteria, etc., these sediments are dried, stained, and examined under an oil-immersion lens. For a discussion of staining methods any standard textbook on bacteriology may be consulted.

Sediments are generally considered in two groups, the organized and the unorganized sediments.

Organized Sediments—These may be roughly classed as follows:

Casts (see Fig. 520) are molds of the uriniferous tubules. Their presence in numbers indicates a diseased kidney, particularly when the albumin content is pronounced. Often a slight toxic condition of the body will cause a few casts to appear for a time in the urine. It may be generally accepted, however, that normal urine contains no casts.

Fig. 520



Casts

1. Hyaline casts.
2. Fine granular casts.
3. Coarse granular casts.
4. Epithelial casts.
5. Blood cell casts (low and high power).
6. Waxy casts.
7. Pus cell casts (low and high power).

Casts are cylindrical, finger-shaped bodies, of varying length. They appear in the urine when the kidney is affected by nephritis, circulatory changes, or toxic irritants. The same causes which produce albuminuria are responsible for casts. They are usually found together, though either may be found without the other.

Hyaline Casts—These are homogeneous and so transparent that the illumination must be considerably cut down in order to see them. They vary much in size, some being very small. They appear with less provocation than other varieties of casts, being found in temporary irritation of the kidneys, after anesthesia, etc. They appear also in connection with other varieties in all forms of nephritis, and may be the only form of cast found in advanced interstitial nephritis.

Granular Casts—The substance of this cast appears finely or coarsely granular and more or less dark looking. Sometimes the base of the cast seems to be hyaline with granules partly filling the clear substance. Granular casts indicate a definite lesion of the kidney and seldom appear except in nephritis. The coarsely granular cast has a more serious significance than the finely granular.

Waxy Casts—These casts are opaque and homogeneous and have a tendency to break off square at the end. They are sometimes twisted or bent and often show transverse cracks. They appear in advanced nephritis and are of serious significance. In acute nephritis, a cast called by many writers "fibrinous" is occasionally found which is difficult to distinguish from "waxy". It is apt to be yellowish or brownish in color.

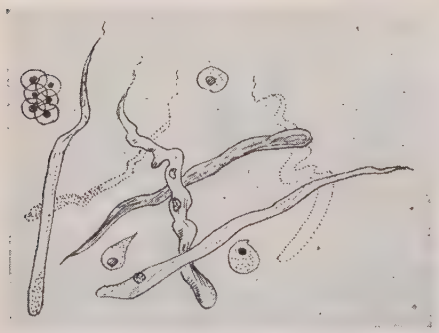
Epithelial Casts—The cells of the tubules or other epithelia compose or cover these casts. Sometimes a hyaline or granular base appears. Sometimes the cast seems entirely formed of epithelial cells.

Blood-cell Casts—These casts are covered by or formed of red blood cells. They appear whenever there is exudation of blood into the kidney tubules, as in acute nephritis.

Pus Casts—A few leukocytes may be attached to casts of any variety, but true pus casts are formed entirely of pus cells. They are found in pyelonephritis, and are always of grave significance.

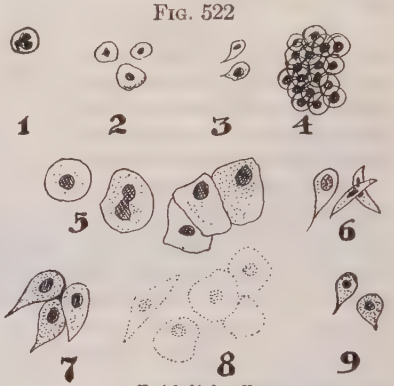
Fatty Casts—These consist of masses of fat globules. They are the product of fatty degeneration of epithelial cells

FIG. 521



Cylindroids
(Few epithelial cells in field)

FIG. 522



Epithelial cells

1. Leukocyte (pus cells) for comparison.
2. Renal cells.
3. Superficial renal pelvic cells.
4. Cells from calices of kidneys.
5. Bladder cells (squamous).
6. Cells from ureter.
7. Bladder cells.
8. Scaly bladder epithelium.
9. Epithelia from prostatic urethra.

composing epithelial casts. If the degeneration is only partial and the cells can still be made out, they usually are called epithelial. They appear in both acute and chronic parenchymatous nephritis.

Pus, blood, and epithelial cells may be found in the same cast. It will take its name from the predominating cells or be called a mixed-cell cast.

CYLINDROIDS (see Fig. 521) are bodies of the apparent composition of hyaline casts, only less solid. One end appears to be molded and the other end stringy and fine. They are considered as being of little significance.

EPITHELIAL CELLS (see Fig. 522)—Some of these are always present. The portion of the urinary tract from which the cells come cannot be definitely located even by those unusually expert in tissue diagnosis. They are of three general types:

Squamous—Large, thin, flat, leaf-like cells, often in sheets; rather small, round nucleus. They come from the bladder, urethra, or vagina.

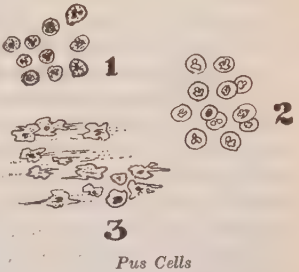
Irregular Cells—Caudate, pyramidal, cylindrical; may come from deep layers of epithelium anywhere in the tract.

Round Cells—Small round cells with comparatively large nuclei, often

slightly granular. These include the renal cells, but cells similar in appearance may come from other portions of the tract. Such cells are not common in normal urine. It is well to report the presence of undue numbers of epithelial cells but not to attempt a description of their origin.

Leukocytes or Pus Cells (see Fig. 523)—These are about twice as large as red blood cells, round granular, with irregular nuclei indistinct or invisible. They may be much or little degenerated. The addition of acetic acid to the slide will clear up the nuclei and make their characteristics more distinct. An occasional leukocyte may be found in normal urine.

Fig. 523



Pus Cells

1. Usual appearance.
2. After addition of acetic acid.
3. Disintegrated pus cells, as in the residual urine of cystitis.

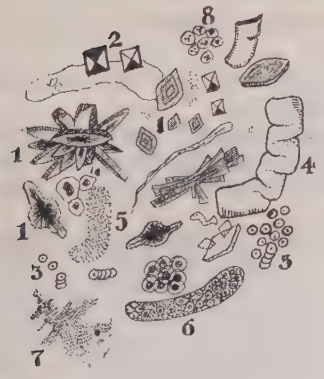
Sources of pus: Urethritis, cystitis, pyelitis, from various bacterial causes, including gonococci and tubercle bacilli. In nephritis a few pus cells may be present.

Erythrocytes or Red Blood Cells—These appear in the urine as the normal biconcave or crenated erythrocyte.

The pathological conditions in which erythrocytes are found in the urinary sediment are as follows:

Hemorrhage of the kidney, of the urinary tract, and from congestion.

Fig. 524



Sediments from acid urine (pathologic)

1. Uric acid crystals.
2. Calcium oxalate crystals.
3. Red blood cells (erythrocytes).
4. Waxy cast.
5. Fine granular cast.
6. Epithelial cast.
7. Amorphous urates.
8. Pus cells.

Fig. 525

Sediments from alkaline urine (pathologic)

1. Thorn apple crystals of ammonium urate.
2. Triple phosphate crystals.
3. Pus cells.
4. Fine granular cast.
5. Coarse granular cast.
6. Hyaline cast.
7. Bacteria.
8. Cylindroid.
9. Cells from calices of kidney.
10. Calcium phosphate crystals.

In the female their presence is not of diagnostic importance as with the male, where they are most frequently indicative of calculus (kidney stone).

Chemical Test for Blood—This is sometimes requested. Either of these two methods may be used for its detection.

Benzidine Test—To about 3 cc. of a saturated solution of benzidine in glacial acetic acid, add an equal volume of solution of hydrogen dioxide and 1

or 2 cc. of the urine to be examined. Shake the tube; in the presence of blood, a blue or green color develops. A control should always be made, using distilled water instead of urine. This is a very sensitive test.

Guaiac Test—Place about 5 cc. of urine in a test tube and add a freshly prepared alcoholic solution of guaiac (1 to 60) until the whole becomes turbid. Then add solution of hydrogen dioxide or old oil of turpentine; a blue color will appear if blood is present.

Unorganized Sediments—These are generally regarded as having but little significance. However, their presence in urine is reported by the analyst, and to the physician such a report may be of diagnostic assistance. A rather complete list of the unorganized sediments (see Figs. 524 and 525), includes the following: *magnesium ammonium phosphate, calcium oxalate, calcium phosphate, calcium sulphate, calcium carbonate, uric acid, urates, cystine, cholesterol, hippuric acid, leucine, and tyrosine.*

The following notes represent rather fully what little there is of diagnostic value in the recognition of the unorganized sediment.

The commonest crystal sediments are the phosphates, urates, oxalates, and uric acid. The phosphates and urates may appear as amorphous sediments, the latter readily dissolving when heated, and the former promptly dissolving upon the addition of acetic acid. Calcium oxalate crystals are generally found in acid urine and are frequently the result of eating rhubarb, asparagus, etc. They are encountered in a variety of forms, as are most of the crystals in urine.

Urates may appear as ammonium, calcium, magnesium, potassium, and sodium urate. The calcium, magnesium, potassium, and sodium urates appear in acid urines, while the sediment of ammonium urate appears in neutral, alkaline, or acid urines.

Sodium urate may be amorphous or crystalline. When crystalline, it appears in sheaves or clusters of colorless needles.

Ammonium urate generally appears in the burr-like form of the "thorn apple", which appears to be balls with spicules attached.

Uric acid crystals, found only in acid urine, are generally amber or brown in color, are found clumped or in single crystals, of an oval tablet shape. They are not readily mistaken for any other crystal formation because of their characteristic pigmentation.

All the crystal forms are illustrated and should be well studied so that identification will be readily made.

CHAPTER LXXXVII

CHEMICAL ASSAY METHODS

EVEN a brief survey of the chemical assay methods of the U. S. P. X reveals the fact that the pharmacist of today is required to possess a rather wide range of chemical knowledge. In the following pages will be found a classified study of the chemical assay processes that the pharmacist is called upon to understand if he is to become a competent analyst.

The assay processes of similar type are considered together, since by associating them in this manner the user will more easily grasp the principles underlying each class of assays. Complex and involved calculations have been omitted so that attention may be concentrated upon the chemical and physical facts involved. A fair knowledge of elemental chemistry and physics is necessary and it is assumed that the student has previously learned what is meant by molecular weights, and their quantitative application to chemical reactions, and it must be remembered that molecular weights represent the proportions in which chemicals react, as it is from these weights that the factors and equivalents given in the texts of the assays have been calculated (see pages 527 to 543).

With this basic knowledge of chemistry and a careful study of the explanations which follow, the pharmacist should be able to understand the various official chemical assay methods and be able to successfully carry out the processes. In every case the official assay method must be strictly followed.

It has been found convenient to arrange the assay processes in four main divisions as follows:

1. Volumetric Assay Methods.
2. Gravimetric Assay Methods.
3. Gasometric Assay Methods.
4. Special Assay Methods.

VOLUMETRIC ASSAY METHODS

This is the most frequent type of assay encountered by the pharmacist in pharmacopœial standardization. Every volumetric determination is based upon the volume of a solution of known strength which is required to complete a chemical reaction with the substance under examination. Such a solution is called a *standard solution* or a *volumetric solution* and is often referred to by means of the abbreviation "V.S.", or in terms of what is called *normality*.

Indicators—It is important to guard against the use of an insufficient amount of a volumetric solution, thus failing to complete a reaction and it is equally necessary to guard against over-stepping a reaction by adding too much of the volumetric solution. To meet this situation an interesting group of chemicals called *indicators* is used. An indicator is a substance that shows the end-point of the reaction, either by a change in the color or by the formation of a precipitate.

Each indicator test solution used in acidimetric or alkalimetric tests must be examined for its sensitiveness. The indicator test solution, unless otherwise directed, should be so adjusted that when 0.15 cc. of the indicator is added to 25 cc. of distilled water, 0.5 cc. of hundredth-normal acid or alkali, respectively, will distinctly develop the characteristic color changes.

Indicator test solutions are injured by exposure to light and should be preserved in dark amber-colored vials. Test papers should be kept in dark bottles. A typical indicator bottle with dropping stopper is shown in Fig. 526.

The indicators most commonly used and recognized by the U. S. P. are as follows:

Brom Cresol Purple (*Dibromo-orthocresol-sulphonphthalein*)—$(OH.C_6H_2Br CH_3)_2CO.C_6H_4SO_2$—Light pink to yellowish crystals (melting point from 241° to 242° C. uncorrected), soluble in alcohol, water, and in solutions of alkali hydroxides and carbonates. Alkaline solutions of brom cresol purple are colored deep purple and exhibit dichromatism, *i.e.*, predominance of red in thick layers and of blue in thin layers. The color is changed to yellow on the addition of acids.

Fig. 526

Indicator bottle

Brom Cresol Purple Test Solution—In an agate mortar, grind 0.1 Gm. of the dry powder with 9.5 cc. of fiftieth-normal sodium hydroxide. When solution is complete, dilute to 250 cc. with boiled-out and cooled distilled water.

This test solution should be deep orange to wine-red in color. If it is purple, the addition of not more than 0.5 cc. of fiftieth-normal acid (to the 250 cc.) should make it wine-red; and if it is yellow, the addition of not more than 0.5 cc. of fiftieth-normal alkali should produce the wine-red coloration. The pH range is from yellow, 5.2 to 6.8, purple. Preserve in glass-stoppered bottles.

Cochineal Test Solution—Macerate 1 Gm. of unbroken cochineal (page 842) during four days with 20 cc. of alcohol and 60 cc. of distilled water, then filter. The color of this test solution is turned violet by alkalies, and yellowish-red by acids. Cochineal T.S. is used in titrating alkaloids.

Litmus—A blue pigment prepared from various species of *Roccella* De Candolle. In blue cubes, masses, fragments, or granules, partly soluble in water and in alcohol.

Litmus Paper—For blue litmus paper, impregnate sheets of white filter paper with litmus T.S. and dry by suspending them on clean cord in a neutral atmosphere.

For red litmus paper, add to litmus T.S. just sufficient of a highly diluted solution of hydrochloric acid to impart to it a faint red tint, impregnate, and dry sheets of filter paper as directed above. The impregnated sheets after drying may be cut into strips as desired. Litmus test papers should respond quickly to one drop of two-hundred-and-fiftieth-normal acid or alkali, respectively. Preserve in well-stoppered bottles.

Litmus Test Solution—Exhaust 25 Gm. of powdered litmus with three successive portions of 100 cc. each of boiling alcohol, continuing each extraction for about one hour. Filter, wash with alcohol and discard the alcoholic filtrate. Digest the residue with about 25 cc. of cold distilled water and filter. Discard this filtrate also. Finally extract the residue with 125 cc. of boiling distilled water and, after thoroughly cooling, filter. Litmus turns red with acids and blue with alkalies. The pH range is from red, 4.5 to 8.3, blue. Litmus is unsuitable for determining alkaloids, carbonates, or bicarbonates. Preserve the filtrate in wide-mouthed bottles, stoppered with loose plugs of purified cotton.

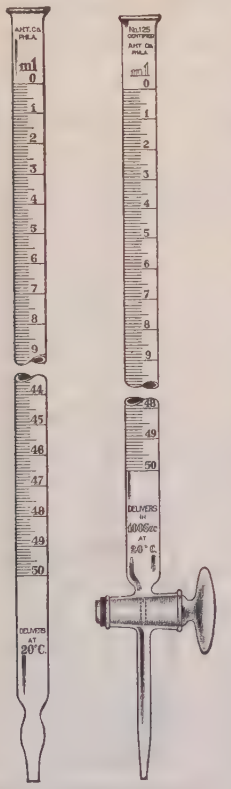
Methyl Orange (*Tropæolin D., Dimethylaniline Orange*)—The sodium salt of paradimethylaminoazobenzene sulphonic acid, $(CH_3)_2$–N–C_6H_4–N = N–C_6H_4. SO_3Na. An orange-yellow powder, slightly soluble in cold water, insoluble in alcohol.

Methyl Orange Test Solution—Dissolve 0.1 Gm. of methyl orange in 100 cc. of distilled water. Methyl orange turns from orange to rose-red with acids, and to yellow with alkalies. This indicator is not suitable for determining organic acids or alkaloids, nor should it be used in alcoholic or in very hot solutions. The pH range is from orange-red, 3.1 to 4.4, yellow.

Methyl Red (*Paradimethylaminoazobenzeneorthocarboxylic Acid*) $(CH_3)_2$–N–C_6H_4–N = N–C_6H_4.COOH—Violet crystals sparingly soluble in cold water, soluble in alcohol.

Methyl Red Test Solution—Dissolve 0.2 Gm. of methyl red in 100 cc. of alcohol. Methyl red turns from red with acids to yellow with alkalies. This solution is unsatisfactory for the determination of carbonates or bicarbonates. It is very satisfactory for many alkaloids. The pH range is from red, 4.2 to 6.3, yellow.

FIG. 527 FIG. 528

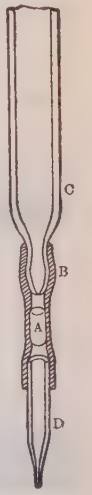


Ordinary burette Glass-valved burette

Phenol Red (*Phenolsulphonphthalein*)—Use *Phenolsulphonphthaleinum*, page 846.

Phenol Red Test Solution—In an agate mortar, grind 0.1 Gm. of the dry powder with 14.5 cc. of fiftieth-normal sodium hydroxide. When solution is complete, dilute to 250 cc. with boiled-out and cooled distilled water. Filter off the insoluble residue. The zone of color transformation of this indicator is from yellow, pH 6.8 to 8.4, red. Preserve in a glass-stoppered bottle.

FIG. 529



Dropping device for burette

Phenolphthalein—Use *Phenolphthaleinum*, page 821.

Phenolphthalein Test Solution—Dissolve 1 Gm. of phenolphthalein in 100 cc. of alcohol. Phenolphthalein is colorless with acids and turns red with alkalies. This test solution is not satisfactory for determining alkaloids, ammonia, carbonates, or bicarbonates in cold solutions. The pH range is from colorless, 8.3 to 10.0, red.

Phenolphthalein Test Paper—Impregnate sheets of white unsized paper with phenolphthalein T.S., dry, and cut into strips of a suitable size. Preserve as directed under litmus paper.

Titration—To *titrate* means to pass a measured volume of a standard solution out of a measuring apparatus called a *burette* into another solution containing the substance, the purity of which is being determined. The performance of this act is spoken of as "carrying out a titration".

Figs. 527 and 528 illustrate two types of burettes. The style shown in Fig. 527 is usually fitted with the dropping device illustrated in Fig. 529. A tightly fitting piece of glass rod (A) is slipped into a section of rubber tube and this connects the burette and glass dropping point. By pinching the tube about "A" the flow of the solution may be accurately controlled.

Figs. 530 and 531 illustrate the usual form of burette stand. Fig. 532 combines the container of the volumetric solution and the stand and is very convenient when large amounts of a solution are to be used.

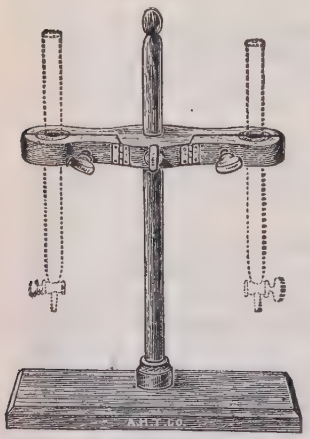
The standard or volumetric solutions used in these titrations contain, in

a given volume, a weight of a dissolved substance which bears a direct relation to its molecular or reacting weight. All normal solutions are equal to each other, volume for volume, in reacting strength, yet rarely, if ever, do any two normal solutions agree in percentage strength, by weight. In one liter of a normal volumetric salt solution there is dissolved the molecular weight of that substance, expressed in grams, divided by its hydrogen equivalent. The application of this statement in preparing volumetric solutions is explained by a consideration of the following equations:

$$\underset{\text{sodium hydroxide}}{NaOH} + \underset{\text{hydrochloric acid}}{HCl} = \underset{\text{sodium chloride}}{NaCl} + \underset{\text{water}}{H_2O}$$

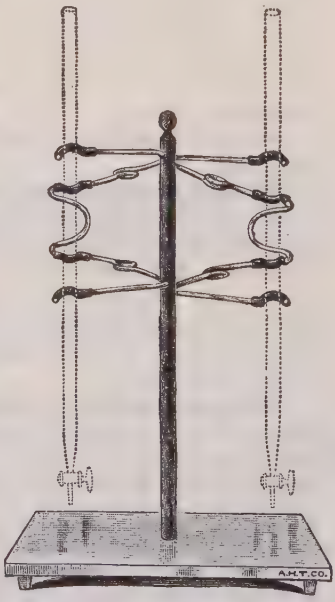
The hydrogen equivalent of both sodium hydroxide and hydrochloric acid is observed to be one. The molecular weight of sodium hydroxide is about forty, and of hydrochloric acid about thirty-six. Therefore, 40 Gm. of 100 per cent sodium hydroxide are required to be dissolved in sufficient distilled water to form one liter of a normal volumetric solution of sodium hydroxide. In one liter of a normal hydrochloric acid solution 36 Gm. of 100 per cent hydrochloric acid

Fig. 530



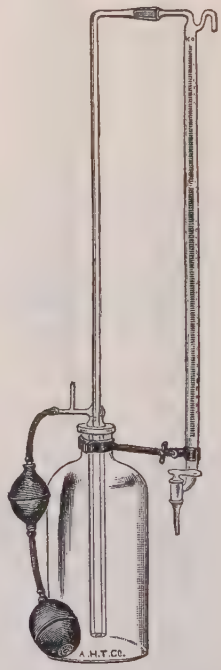
Burette stand

Fig. 531



Burette stand

Fig. 532



Burette stand with stock of V. S. and filler

are required. It follows then that just as forty parts of sodium hydroxide react with thirty-six parts of hydrochloric acid so will one liter of normal sodium hydroxide volumetric solution react with one liter of normal hydrochloric acid volumetric solution.

$$\underset{\text{sodium hydroxide}}{2NaOH} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{sodium sulphate}}{Na_2SO_4} + \underset{\text{water}}{2H_2O}$$

Since one molecule of sulphuric acid contains two atoms of replaceable hydrogen and reacts with two molecules of sodium hydroxide, its hydrogen

equivalent is clearly two instead of one. It follows then that a liter of normal solution of sulphuric acid should contain not 98 Gm. of the 100 per cent acid, corresponding to its molecular weight, but one-half of that amount, or 49 Gm. Such a solution will react with all other normal solutions, volume for volume.

There are times when the hydrogen equivalent is determined only from a knowledge of the work that a chemical substance is required to perform. Potassium dichromate, for example, is invariably used as an oxidizing agent and as such each molecule is capable of liberating six atoms of iodine from potassium iodide, as follows:

$$\underset{\text{potassium dichromate}}{K_2Cr_2O_7} + 6KI + \underset{\text{sulphuric acid}}{7H_2SO_4} = \underset{\text{potassium sulphate}}{4K_2SO_4} + \underset{\text{chromic sulphate}}{Cr_2(SO_4)_3} + \underset{\text{iodine}}{3I_2} + \underset{\text{water}}{7H_2O}$$

The hydrogen equivalent of iodine is one, since each atom combines with an atom of hydrogen to form a molecule of hydriodic acid. It will be observed from the above equation that the hydrogen equivalent of potassium dichromate is six, since each molecule of the dichromate displaces six atoms of iodine from an iodide. Thus, the amount of potassium dichromate dissolved in a liter to form a normal solution corresponds to one-sixth of its molecular weight as expressed in grams.

A *tenth-normal solution* is only one-tenth as concentrated as a normal solution of that particular substance and is generally indicated by means of the expression "$\frac{N}{10}$"; the *fiftieth-normal solutions* are one-fiftieth the normal concentration and are indicated by "$\frac{N}{50}$"; a *two-hundredth normal* solution is referred to as "$\frac{N}{200}$"; while *double-normal solutions* are of twice the normal concentration and are designated by the expression "$\frac{2}{N}$".

With this understanding the volumetric assays will be considered in their appropriate groupings.

Assay Methods Based Upon the Principle of Neutralization.

The following official substances are required to be assayed by direct titration with normal sodium hydroxide:

Using phenolphthalein as the indicator—*Acetic Acid, Diluted Acetic Acid, Glacial Acetic Acid, Boric Acid, Citric Acid, Tartaric Acid, Trichloracetic Acid, Potassium Bitartrate and Sodium Biphosphate.*

Using methyl orange as the indicator—*Hydrochloric Acid, Diluted Hydrochloric Acid, Hypophosphorous Acid, Nitric Acid, Sulphuric Acid, and Diluted Sulphuric Acid.*

Each of the above substances is titrated in aqueous solution, with the exception of boric acid which is dissolved in a mixture of equal parts of water and glycerin.

The following are dissolved in neutral alcohol and titrated with tenth-normal sodium hydroxide, phenolphthalein being used as indicator:

Cinchophen, Eucaine Hydrochloride.

To an accurately weighed portion of the substance, in solution, the indicator is added and the mixture titrated with the standard alkali until the indicator shows by a change in color that the end of the reaction has been

reached. The following equation will serve as an illustration of all of the above acid substances to which this type of assay process is applied:

$$\underset{\text{nitric acid}}{HNO_3} + \underset{\substack{\text{sodium}\\\text{hydroxide}}}{NaOH} = \underset{\substack{\text{sodium}\\\text{nitrate}}}{NaNO_3} + \underset{\text{water}}{H_2O}$$

Cinchophen and eucaine hydrochloride are dissolved in neutral alcohol because of their sparing solubility in water. Sodium chloride is added to the solution of sodium biphosphate in order to prevent ionization and thereby secure a sharper and more reliable end-point. The results are easily calculated by making use of the equivalents given in the official text.

The following acid is assayed by direct titration with normal potassium hydroxide in the presence of phenolphthalein as the indicator:

Formic Acid—The formic acid is neutralized in the titration with the formation of potassium formate according to the following equation:

$$\underset{\text{formic acid}}{HCOOH} + \underset{\substack{\text{potassium}\\\text{hydroxide}}}{KOH} = \underset{\substack{\text{potassium}\\\text{formate}}}{HCOOK} + \underset{\text{water}}{H_2O}$$

The number of cc. of normal potassium hydroxide used is then converted into the weight of formic acid found, by means of the factor given in the N. F. text.

Residual Titrations with Excess of Alkali.

Residual titrations of this group, are those in which the substance being assayed is treated with an excess of standard sodium hydroxide solution, the amount of excess being estimated by subsequent titration with standard acid solution of the same degree of normality.

Acetylsalicylic Acid—This substance, being both an ester and an acid, is completely neutralized and saponified by gently boiling for ten minutes with an excess of half-normal sodium hydroxide. Phenolphthalein is added as the indicator, and the excess of alkali estimated by titration with half normal sulphuric acid. A blank test is carried out, omitting the acetylsalicylic acid and the amount of half-normal alkali consumed by the sample is determined by difference.

Lactic Acid—A carefully weighed portion of the lactic acid is boiled for twenty minutes with an excess of normal sodium hydroxide in order to convert the lactones and inner anhydrides into lactate. The excess of alkali is then estimated by titration with normal sulphuric acid while the solution is still hot, using phenolphthalein as the indicator. A blank test is made, omitting the lactic acid, and, by comparison, the amount of normal alkali consumed by the lactic acid is determined.

Aromatic Sulphuric Acid—This acid is first treated with an excess of normal sodium hydroxide and the mixture evaporated to dryness to remove the interfering volatile organic matter. The residue is dissolved in distilled water, methyl orange added as the indicator, and the solution titrated with normal sulphuric acid.

Solution of Formaldehyde and Paraformaldehyde—Both solution of formaldehyde and of paraformaldehyde are oxidized to formic acid by warming with a solution of H_2O_2, in the presence of an excess of normal sodium hydroxide which immediately converts the formic acid into sodium formate. The mixture is cooled, litmus is added as the indicator, and the excess of alkali estimated by titrating with normal sulphuric acid. The difference between the number of cc. of normal alkali and of normal acid used, represents the number of cc.

of normal sodium hydroxide that are equivalent to the formic acid obtained from the solution of formaldehyde (or from the paraformaldehyde) originally taken. The oxidation of formaldehyde to formic acid is shown by the following equation:

$$\underset{\text{formaldehyde}}{HCHO} + \underset{\substack{\text{hydrogen}\\\text{dioxide}}}{H_2O_2} = \underset{\text{formic acid}}{HCOOH} + \underset{\text{water}}{H_2O}$$

It is difficult to obtain a sharp and dependable end-point by the direct titration of substances like the above with standard alkali. For this reason a completed reaction is assured by adding more than the required amount of standard sodium hydroxide solution. The excess of free alkali is then conveniently estimated by titrating with a standard acid solution of the same volumetric concentration, in the presence of the appropriate indicator.

Calcium Lactophosphate—The conditions in this assay are such as to bring about the precipitation of the phosphate radical as ammonium phosphomolybdate. This precipitate is washed and then dissolved in an excess of half-normal sodium hydroxide. The reaction that takes place is illustrated by the following equation:

$$\underset{\text{ammoniumphosphomolybdate}}{2(NH_4)_3PO_4.12MoO_3} + \underset{\substack{\text{sodium}\\\text{hydroxide}}}{46NaOH} = \underset{\substack{\text{di-ammonium}\\\text{phosphate}}}{2(NH_4)_2HPO_4} + \underset{\substack{\text{ammonium}\\\text{molybdate}}}{(NH_4)_2MoO_4}$$

$$+ \underset{\text{sodium molybdate}}{23Na_2MoO_4} + 22H_2O$$

The excess of alkali is then estimated by titration with half-normal hydrochloric acid, phenolphthalein serving as the indicator. The amount of half-normal sodium hydroxide consumed is then determined by difference and is converted into terms of P_2O_5 by using the factor given in the N. F. text.

Assays by Neutralization with Sulphuric Acid.

The following official substances are assayed by direct titration with sulphuric acid volumetric solution:

Ammonium Carbonate, Ammonia Water, Stronger Ammonia Water, Lime Water, Potassium Carbonate, Potassium Bicarbonate, Sodium Bicarbonate, Monohydrated Sodium Carbonate.

In the estimation of lime water, tenth-normal sulphuric acid is employed, as the standard solution, and the indicator is phenolphthalein. All of the others are titrated with normal sulphuric acid, using methyl orange as the indicator.

The above alkaline substances are easily determined by utilizing their ability to neutralize acids. The standard acid solution neutralizes their alkalinity to form neutral sulphates and water as exemplified by the following equation:

$$\underset{\substack{\text{potassium}\\\text{carbonate}}}{K_2CO_3} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{H_2SO_4} = \underset{\substack{\text{potassium}\\\text{sulphate}}}{K_2SO_4} + \underset{\substack{\text{carbon}\\\text{dioxide}}}{CO_2} + \underset{\text{water}}{H_2O}$$

Assay of Alkali Salts of Organic Acids.

In this type of assay the organic salts of metals are first converted into carbonates by ignition and then estimated by means of sulphuric acid volumetric solution. The following are assayed by this method:

Solution of Potassium Citrate and Solution of Sodium Citrate—The solvent is first removed from these solutions by evaporation.

Potassium Acetate, Potassium Citrate, and Potassium and Sodium Tartrate, Compound Effervescing Powder—To assay for the potassium bitartrate content. Since this powder also contains sodium bicarbonate, it is necessary to subtract, from the volume of standard acid required to neutralize the ignited residue, the number of cc. of standard acid required to neutralize the sodium bicarbonate also present in the weight of material taken. This is previously determined before the material is ignited.

Sodium Acetate, Sodium Citrate, Lithium Citrate, and Lithium Salicylate—In each of the above determinations the standard acid solution used is half-normal sulphuric acid and the indicator is methyl orange. The following directions from the U. S. P. X apply to all of these determinations:

"Heat about 2 Gm. of the salt, accurately weighed, in a platinum or porcelain crucible, heating at first very gently, then gradually raising the temperature until the salt is thoroughly carbonized. (*Caution—Do not use platinum crucibles for lithium salts.*) The final temperature must not exceed a dull red heat and the flame of the burner must not come into contact with the carbonized mass. After allowing the carbonized mass to cool, moisten with distilled water, ignite again, and repeat the moistening and igniting until a white residue is obtained. Then disintegrate the ignited mass with the aid of a stout glass rod and transfer the mass and crucible to a beaker. Add 50 cc. of distilled water and titrate with half-normal sulphuric acid, using methyl orange T.S. as indicator. The number of cc. of half-normal sulphuric acid used, multiplied by the proper equivalent of the salt, represents the amount of salt present in the quantity taken."

The change that takes place in the ignition of a salt of this type may be shown in a general way, by the following equation:

$$\underset{\text{potassium acetate}}{2KC_2H_3O_2} + \underset{\text{oxygen}}{4O_2} = \underset{\text{potassium carbonate}}{K_2CO_3} + \underset{\text{carbon dioxide}}{3CO_2} + \underset{\text{water}}{3H_2O}$$

The product of the ignition, namely potassium carbonate, is then neutralized by titrating with a standard acid solution according to the following equation:

$$\underset{\text{potassium carbonate}}{K_2CO_3} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

Strontium Salicylate—In this assay the residue of carbonate is dissolved in standard hydrochloric acid, rather than sulphuric acid. The assay is related, in principle, to those explained above.

Assays by Neutralization with Barium Hydroxide.

The following substances are required to be determined by titration with tenth-normal barium hydroxide volumetric solution:

Benzoic Acid—Because of its sparing solubility in water, benzoic acid is dissolved in neutral alcohol. After adding the indicator the solution is ready for titration with the standard barium hydroxide.

Salicylic Acid—The explanation for this assay is similar to that just given for benzoic acid.

Ammonium Benzoate, Caffeine Sodio-Benzoate, Ammonium Salicylate, and Theobromine Sodio-Salicylate—These are first dissolved, then decomposed by sulphuric acid, and the separated organic acid is extracted with successive portions of chloroform. After removing the chloroform by evaporation, the acid is dissolved in neutral alcohol and then titrated by the standard barium hydroxide

solution. This method applies only to the estimation of the organic acids present, the caffeine and the theobromine being first removed and estimated by a gravimetric method explained (see page 1476).

The indicator used in all of the above determinations is phenolphthalein. Standard barium hydroxide solution is more satisfactory than a standard solution of a caustic alkali for titrating benzoic and salicylic acids because a sharper end-point is obtained. The reaction that takes place in a titration of this type is illustrated by the following equation:

$$\underset{\text{benzoic acid}}{2HC_7H_5O_2} + \underset{\substack{\text{barium}\\\text{hydroxide}}}{Ba(OH)_2} = \underset{\substack{\text{barium}\\\text{benzoate}}}{Ba(C_7H_5O_2)_2} + \underset{\text{water}}{2H_2O}$$

Residual Titrations with Excess of Sulphuric Acid.

In assay methods of the residual type, more than sufficient standard acid is added and the excess determined by titration with standard alkali.

Solution of Ammonium Acetate, Solution of Iron and Ammonium Acetate, Ammonium Phosphate, and Sulphonated Bitumen—The ammonia content in each of the foregoing is determined by first liberating the ammonia with sodium hydroxide and distilling in such a way as to receive the ammonia in an excess of standard sulphuric acid. Methyl orange is then added as the indicator and the excess of acid estimated by titrating with standard sodium hydroxide. The results are calculated to ammonium acetate in the solution of ammonium acetate, and to total ammonia in the solution of iron and ammonium acetate and in the sulphonated bitumen.

Milk of Magnesia, Magnesium Carbonate, Magnesium Oxide, and Zinc Oxide—In these four determinations the substance is dissolved in a measured excess of normal sulphuric acid, methyl orange is added as the indicator, and the excess of acid is estimated with normal sodium hydroxide.

Compound Effervescing Powder—To assay for the sodium bicarbonate content, half-normal sulphuric acid is used in excess and, after boiling off the carbon dioxide, the residual acid is estimated with half-normal sodium hydroxide, phenolphthalein serving as the indicator.

Sodium Benzoate and Sodium Salicylate—These salts are estimated in accordance with the principles described under the assay of alkali salts of organic acids, employing the residual instead of the direct method of titration. The official directions for determining these salts as given in the U. S. P. X are as follows:

"Dry about 2 Gm. of the salt to constant weight at from 100° to 110° C., weigh accurately in a platinum or porcelain crucible, and heat at first gently, then gradually raise the temperature until the salt is thoroughly carbonized. The final temperature must not exceed a dull red heat and the flame of the burner must not come in contact with the carbonized mass. Allow the carbonized mass to cool, disintegrate it well with a stout glass rod or powder carefully, and transfer with the crucible to a beaker or casserole. Add 50 cc. of distilled water and 50 cc. of half-normal sulphuric acid, cover the beaker or casserole with a watch-glass and boil for thirty minutes. Filter and wash the residue with hot distilled water until the washings cease to redden blue litmus paper. Dry the residue and filter paper and ignite as described above.

"Transfer the ignited residue to the filtrate and determine the excess of acid in the cooled filtrate by titration with half-normal sodium hydroxide, using methyl orange T.S. as indicator. The volume of half-normal sulphuric acid

consumed, multiplied by the proper equivalent of the salt, represents the amount of salt present in the quantity taken."

Zinc Stearate—A weighed portion of zinc stearate is boiled with an excess of tenth-normal sulphuric acid for ten minutes. This brings about double decomposition, forming soluble zinc sulphate and insoluble stearic acid. The mixture is cooled, then filtered to remove stearic acid, methyl orange is added, and the solution is titrated with tenth-normal sodium hydroxide to estimate the amount of sulphuric acid present in excess. The amount of tenth-normal acid consumed is determined by difference and the results are calculated to zinc oxide.

Codeine Phosphate—The free alkaloid is liberated by adding an excess of sodium hydroxide to an aqueous solution of the salt, extracting with successive portions of chloroform and removing the chloroform by evaporation. The residue of alkaloid is then dissolved in an excess of tenth-normal sulphuric acid, with the aid of a gentle heat, which assists in getting rid of any remaining chloroform. The amount of acid in excess is then estimated by adding methyl red as the indicator and titrating with tenth-normal sodium hydroxide. The amount of tenth-normal acid consumed by the alkaloid is then easily determined and the result is multiplied by the equivalent of codeine, given in the text.

Methenamine—This compound is boiled with an excess of normal sulphuric acid until the odor of formaldehyde is no longer perceptible. The heating brings about a hydrolytic decomposition of the methenamine as follows:

$$\underset{\text{methenamine}}{(CH_2)_6N_4} + \underset{\text{water}}{6H_2O} = \underset{\text{formaldehyde}}{6HCHO} + \underset{\text{ammonia}}{4NH_3}$$

The formaldehyde is expelled but the ammonia immediately combines with a corresponding amount of the normal sulphuric acid to form ammonium sulphate, according to the following equation:

$$\underset{\text{ammonia}}{4NH_3} + \underset{\text{sulphuric acid}}{2H_2SO_4} = \underset{\text{ammonium sulphate}}{2(NH_4)_2SO_4}$$

The excess of normal sulphuric acid is tnen estimated in the usual manner by titrating with normal sodium hydroxide in the presence of methyl orange as the indicator.

Prepared Calamine—The ignited calamine, consisting chiefly of zinc oxide, is warmed with a measured excess of normal sulphuric acid. To the extent that there is oxide in this residue the acid is consumed as follows:

$$\underset{\text{zinc oxide}}{ZnO} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{zinc sulphate}}{ZnSO_4} + \underset{\text{water}}{H_2O}$$

The excess of sulphuric acid is then determined by titrating with normal alkali in the presence of methyl orange as the indicator. The amount of normal sulphuric acid consumed by the calamine can then easily be determined by difference.

Lithium Carbonate—A weighed portion of this salt is dissolved in an excess of normal sulphuric acid. The change that takes place is illustrated by the following equation:

$$\underset{\text{lithium carbonate}}{Li_2CO_3} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{lithium sulphate}}{Li_2SO_4} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

The unused sulphuric acid is then estimated with normal potassium hydroxide, methyl orange being used as the indicator. The difference between the number of cc. of normal acid and normal alkali used represents the figure that is to be multiplied by the factor given in the N. F. text, the result being the weight of lithium carbonate found.

Assays by Neutralization with Hydrochloric Acid.

In the following assays the determinations involve direct titration with normal hydrochloric acid.

Potassium Hydroxide, Solution of Potassium Hydroxide, Sodium Hydroxide, and Solution of Sodium Hydroxide—Each of these four substances absorbs carbon dioxide from the air and contains varying amounts of the alkali carbonate. The presence of carbonate interferes with the accuracy of the titration. For this reason the official procedure requires that the carbonate be first removed as insoluble barium carbonate by agitating a solution of the substance in boiled and cooled distilled water with an excess of barium chloride test solution. Sufficient boiled and cooled distilled water is added to bring the mixture to a definite volume. After filtering the mixture and rejecting the first portion of the filtrate, an aliquot portion is titrated with normal hydrochloric acid, phenolphthalein being used as the indicator.

Sodium Borate and Sodium Cacodylate—Advantage is taken of the hydrolysis and subsequent alkalinity of these salts in aqueous solution. A weighed portion of the salt is dissolved in distilled water and the extent of the alkalinity is determined by direct titration with normal hydrochloric acid, methyl orange being used as the indicator. Sodium cacodylate is sometimes made neutral to phenolphthalein, but this does not affect the accuracy of the titration, since true sodium cacodylate is indifferent to phenolphthalein.

All of the above titrations are based upon the simplest type of equations involving neutralization, as for example:

$$\underset{\text{potassium hydroxide}}{KOH} + \underset{\text{hydrochloric acid}}{HCl} = \underset{\text{potassium chloride}}{KCl} + \underset{\text{water}}{H_2O}$$

Sodium Glycerophosphate—(In this case half-normal instead of normal hydrochloric acid is used.)

Sodium glycerophosphate is alkaline to methyl orange and is converted during the titration into the mono-sodium salt which is neutral to this indicator. The reaction is explained as follows:

$$\underset{\text{di-sodium glycerophosphate}}{C_3H_5(OH)_2Na_2PO_4} + \underset{\text{hydrochloric acid}}{HCl} = \underset{\text{mono-sodium glycerophosphate}}{C_3H_5(OH)_2NaHPO_4} + \underset{\text{sodium chloride}}{NaCl}$$

The factor given in the N. F. text corresponds to this equation and needs only to be multiplied by the number of cc. of half-normal hydrochloric acid used to furnish the weight of sodium glycerophosphate found.

Residual Titrations Using an Excess of Hydrochloric Acid.

These residual titrations involve the use of an excess of standard hydrochloric acid, and the subsequent estimation of this excess by titrating with standard alkali.

Calcium Lactate—This salt is first converted into calcium oxide by incineration. The oxide is then dissolved in an excess of half-normal hydrochloric acid, which is used in preference to sulphuric acid because of the sparing solubility

of calcium sulphate. The amount of acid in excess is then estimated by titrating with half-normal sodium hydroxide, methyl orange being used as the indicator.

Benzaldehyde, and Oil of Bitter Almond (for benzaldehyde content)—Phenylhydrazine reacts with aldehydes and hence is used in estimating the aldehyde content of the two foregoing substances. It is also basic in character, since it combines with acids to form salt-like bodies. In the assay of benzaldehyde, for example, an alcoholic solution of phenylhydrazine is prepared and a definite volume of this is titrated with half-normal hydrochloric acid, methyl orange being used as the indicator. Neutralization takes place as follows:

$$\underset{\text{phenylhydrazine}}{C_6H_5HNNH_2} + \underset{\substack{\text{hydro-}\\\text{chloric acid}}}{HCl} = \underset{\substack{\text{phenylhydrazine}\\\text{hydrochloride}}}{C_6H_5HNNH_2HCl}$$

To an equal volume of the same alcoholic solution of phenylhydrazine a weighed portion of benzaldehyde is added. A condensation product is formed between the phenylhydrazine and the benzaldehyde according to the following equation:

$$\underset{\text{benzaldehyde}}{C_6H_5CHO} + \underset{\text{phenylhydrazine}}{H_2NNHC_6H_5} = \underset{\text{benzal phenylhydrazone}}{C_6H_5CHNNHC_6H_5} + \underset{\text{water}}{H_2O}$$

The unused phenylhydrazine is then neutralized by adding an excess of half-normal hydrochloric acid and filtering the mixture. The amount of acid in excess is determined by titrating the filtrate and washings with half-normal sodium hydroxide, using methyl orange as the indicator. The number of cc. of half-normal hydrochloric acid that corresponds to the original benzaldehyde is then calculated from the above titrations, by difference, and the result is multiplied by the equivalent given in the text.

Oil of Lemon—Here again phenylhydrazine is employed in estimating the aldehyde *citral* which is a normal constituent. The reaction is explained by the following equation:

$$\underset{\text{citral}}{C_9H_{15}CHO} + \underset{\text{phenylhydrazine}}{H_2NNHC_6H_5} = \underset{\text{citral phenylhydrazone}}{C_9H_{15}CHNNHC_6H_5} + \underset{\text{water}}{H_2O}$$

The main features of this assay are similar to those just explained under benzaldehyde.

Residual Titration Using an Excess of Sodium Hydroxide.

These assays require the residual titration of normal sodium hydroxide by means of normal sulphuric acid, following a special reaction on the part of the alkali.

Chloral Hydrate—Normal sodium hydroxide is added in excess to an aqueous solution of the chloral hydrate and the residual alkali is estimated by titration with normal sulphuric acid, phenolphthalein being used as the indicator. When chloral hydrate is treated with caustic alkali, equal molecular proportions of chloroform and an alkali formate are produced. The assay of chloral hydrate is based upon this behavior. The following equation illustrates what takes place:

$$\underset{\text{chloral hydrate}}{CCl_3CHO.H_2O} + \underset{\substack{\text{sodium}\\\text{hydroxide}}}{NaOH} = \underset{\substack{\text{chloro-}\\\text{form}}}{CHCl_3} + \underset{\substack{\text{sodium}\\\text{formate}}}{NaCHO_2} + \underset{\text{water}}{H_2O}$$

Residual Titrations Involving Saponification of Esters.

The following residual titrations involve the saponification of an ester by means of half-normal alcoholic potassium hydroxide and the subsequent titration of the residual alkali with half-normal acid, phenolphthalein being used as the indicator.

Methyl Salicylate and Oil of Dwarf Pine Needles, Oil of Bergamot—All three of these liquids are assayed for their ester content only.

Oil of Lavender and Oil of Santal—These oils are first acetylized in order to convert the alcohols present into esters, the acetates of the corresponding alcohols, which are then determined by saponification in the usual manner.

Oil of Peppermint and Oil of Rosemary—The ester and the alcohol content of both of these oils should be determined, the ester content by the usual saponification method and the aromatic alcohol content by acetylization, followed by saponification.

Alcoholic potassium hydroxide solution is used in all of these determinations because the alcohol serves as a mutual solvent. In the assay for methyl salicylate the residual alkali is determined with half-normal hydrochloric acid, but in all the others it is determined by means of half-normal sulphuric acid.

The determinations in this group are based upon the principle that esters are capable of being saponified or hydrolyzed by the action of caustic alkali. The actual saponification is carried out with the aid of the heat of a water bath and under a reflux condenser.

In the assays requiring acetylization advantage is taken of the fact that alcohols are basic in character, and, under certain conditions, can be made to react with acids or acid anhydrides to form esters. In acetylizing the above oils their alcohols are converted into acetates by the action of acetic anhydride in the presence of anhydrous sodium acetate. When acetylization is complete, the total activity of the oil, now in the form of ester, can be determined by saponification with standard alkali.

The following equation illustrating the saponification of methyl salicylate is given as typical of a reaction of this kind:

$$\underset{\text{methyl salicylate}}{CH_3C_7H_5O_3} + \underset{\substack{\text{potassium}\\\text{hydroxide}}}{KOH} = \underset{\substack{\text{methyl}\\\text{alcohol}}}{CH_3OH} + \underset{\substack{\text{potassium}\\\text{salicylate}}}{KC_7H_5O_3}$$

It will be observed that only to the extent that there is ester present will the alkali be consumed. The excess of alkali is determined by titration with standard acid solution, the difference in the number of cc. is noted, and the calculation is made by applying the equivalent that appears in the text of the assay.

VOLUMETRIC ASSAY METHODS INVOLVING PRECIPITATION

Assays in Which Potassium Thiocyanate is Used.

This method is used for substances which are assayed by direct titration with tenth-normal potassium thiocyanate, ferric-alum being used as the indicator.

Yellow Mercuric Oxide, Red Mercuric Oxide—These are first dissolved in nitric acid which produces mercuric nitrate and water, which is then titrated.

Mercuric Salicylate—This is first digested with a mixture of sulphuric and nitric acids to bring about complete oxidization and to convert the mercury into sulphate.

Mercury—A solution of mercuric nitrate is first formed by dissolving this metal in an excess of nitric acid: This is then titrated.

Mercury with Chalk—This powder is first dissolved in nitric acid to obtain the mercury in the form of the soluble mercuric nitrate. It is then titrated.

Mild Mercurial Ointment and Strong Mercurial Ointment—The mercury in both of these ointments is converted into mercuric nitrate by dissolving in nitric acid. It is then titrated.

Mass of Mercury—After the disintegration of the mass, the mercury is converted into nitrate by dissolving in nitric acid. It is then titrated.

Solution of Arsenous and Mercuric Iodide—The mercuric content of this solution is determined by first reducing the mercuric iodide to metallic mercury by means of formaldehyde. The mercury is then washed, dissolved in nitric acid, and the mercuric nitrate titrated.

It will be noted that the aim in each of the above preliminary treatments is to convert the mercury into a soluble mercuric salt. From this point the assays are practically identical and the actual titration by means of the standard potassium thiocyanate solution may be explained by the following equation:

$$\underset{\text{mercuric nitrate}}{Hg(NO_3)_2} + \underset{\text{potassium thiocyanate}}{2KCNS} = \underset{\text{mercuric thiocyanate}}{Hg(CNS)_2} + \underset{\text{potassium nitrate}}{2KNO_3}$$

The following silver compounds are assayed by this method:

Silver Nitrate and Fused Silver Nitrate—Both of these are in the desired form for solution and titration.

Strong Silver Protein and Mild Silver Protein—These compounds are first converted into silver nitrate by ignition and solution in nitric acid.

The chemistry involved in the titration of the above silver compounds with potassium thiocyanate is explained by the following equation:

$$\underset{\text{silver nitrate}}{AgNO_3} + \underset{\text{potassium thiocyanate}}{KCNS} = \underset{\text{silver thiocyanate}}{AgCNS} + \underset{\text{potassium nitrate}}{KNO_3}$$

Titrations with potassium thiocyanate volumetric solution are carried out in the presence of diluted nitric acid and with ferric alum as the indicator. This standard solution is used in the estimation of the metals yielding thiocyanates which are insoluble in water, particularly those of silver and mercury. The gradual addition of standard potassium thiocyanate reacts with an increasing amount of the nitrate of silver or of mercury until they have been completely precipitated as the insoluble, white, silver or mercury thiocyanate. The ferric-alum indicator then gives warning of the slightest excess of the standard solution, by the formation of the deep red ferric thiocyanate. The presence of even a trace of ferric thiocyanate in a white mixture gives a faint pink color and the appearance of this color is a sign of the completion of the titration.

Residual Titration Using an Excess of Silver Nitrate.

In these assays a precipitate of insoluble silver salt is formed by the addition of an excess of tenth-normal silver nitrate, and the residual silver nitrate is subsequently estimated by titration with tenth-normal potassium thiocyanate, using ferric-alum as the indicator.

Diluted Hydriodic Acid, Ammonium Bromide, Arsenous Iodide, Calcium Bromide, Potassium Bromide, Potassium Iodide, Sodium Bromide, Sodium Iodide, Syrup of Hydriodic Acid, Syrup of Ferrous Iodide, and Lithium Bromide—A weighed portion of each of the above substances is precipitated from aqueous solution as the insoluble silver iodide or bromide, by adding an excess of tenth-normal silver nitrate. Ferric-alum indicator and diluted nitric acid

are then added and the mixture titrated with tenth-normal potassium thiocyanate until a permanent pink color appears in the supernatant liquid. The following is a typical equation to illustrate the reaction that takes place in the original precipitation:

$$\underset{\text{ammonium bromide}}{NH_4Br} + \underset{\text{silver nitrate}}{AgNO_3} = \underset{\text{silver bromide}}{AgBr} + \underset{\text{ammonium nitrate}}{NH_4NO_3}$$

Solution of Potassium Iodide—A measured portion of this solution is assayed according to the method described above for potassium iodide.

Lead Iodide—Sodium hydroxide solution is used in this assay for the purpose of dissolving the lead iodide. The lead iodide is then determined in the usual manner according to the method outlined above.

Ammonium Chloride, Solution of Zinc Chloride, Sodium Chloride, Calcium Chloride, Zinc Chloride, Magnesium Chloride, and Potassium Chloride—The essential difference in the estimation of the foregoing chlorides lies in the fact that the insoluble silver chloride is removed from the precipitating mixture by filtration and the residual silver nitrate is estimated in an aliquot portion of the filtrate. The precipitation of a chloride by means of standard silver nitrate may be illustrated as follows:

$$\underset{\text{silver nitrate}}{2AgNO_3} + \underset{\text{zinc chloride}}{ZnCl_2} = \underset{\text{silver chloride}}{2AgCl} + \underset{\text{zinc nitrate}}{Zn(NO_3)_2}$$

Potassium Nitrate—This salt is converted into potassium chloride by repeatedly evaporating to dryness with hydrochloric acid. It is then estimated as a chloride according to the above description.

Volatile Oil of Mustard—An alcoholic solution of this oil is heated with an excess of tenth-normal silver nitrate, in the presence of ammonia, to completely hydrolyze the allyl-isothiocyanate and form the insoluble silver thiocyanate. The measuring flask containing this mixture is heated on a water bath and is connected with a reflux condenser. The mixture is then cooled, brought to the required volume with distilled water, and filtered and the residual silver nitrate is estimated by titrating an aliquot portion of the filtrate with tenth-normal potassium thiocyanate.

Black Mustard—After macerating with water, alcohol is added and the mixture is distilled, the distillate being received in a mixture of ammonia water and tenth-normal silver nitrate. From there on the procedure is similar to that described above for volatile oil of mustard, since it is this oil which is found in the distillate.

Phosphoric Acid, Diluted Phosphoric Acid, Sodium Biphosphate, Sodium Phosphate, and Exsiccated Sodium Phosphate—All of these are precipitated as silver phosphate in a solution which is, or has been made, neutral to phenolphthalein. Upon the addition of an excess of silver nitrate, nitric acid is formed in every case. Using sodium phosphate as an illustration the equation would be as follows:

$$\underset{\text{sodium phosphate}}{Na_2HPO_4} + \underset{\text{silver nitrate}}{3AgNO_3} = \underset{\text{silver phosphate}}{Ag_3PO_4} + \underset{\text{nitric acid}}{HNO_3} + \underset{\text{sodium nitrate}}{2NaNO_3}$$

The nitric acid is kept neutralized by adding sufficient zinc oxide to render the mixture neutral to litmus, as some of the precipitated silver phosphate would otherwise dissolve. The mixture is filtered and the residual silver

nitrate is determined by titrating an aliquot portion of the filtrate with tenth-normal potassium thiocyanate.

The conditions for titrating are the same as those employed for the preceding group. Diluted nitric acid is the accessory reagent, ferric-alum is the indicator, and tenth-normal silver nitrate is the substance actually being determined in the titration. The excess of standard silver nitrate is employed in each case for the purpose of insuring the complete precipitation of the insoluble silver compound. The difference between the amounts of the two standard solutions used represents the number of cc. of tenth-normal silver nitrate actually consumed in precipitating the substance being assayed.

Calcium Hypophosphite, Potassium Hypophosphite, and Sodium Hypophosphite—The three foregoing hypophosphites are first oxidized to phosphates by repeated evaporation to dryness with nitric acid. The oxidation of a hypophosphite to phosphate by means of nitric acid is explained by the following equation which applies to the oxidation of sodium hypophosphite:

$$\underset{\text{sodium hypophosphite}}{3NaH_2PO_2} + \underset{\text{nitric acid}}{4HNO_3} = \underset{\text{mono-sodium phosphate}}{3NaH_2PO_4} + \underset{\text{nitric acid}}{2N_2O_2} + \underset{\text{water}}{2H_2O}$$

They are then estimated as phosphates according to the description given above.

Ammonium Hypophosphite—The ammonia is first expelled from this salt by boiling with sodium hydroxide, the reaction is explained by the following equation:

$$\underset{\text{ammonium hypophosphite}}{NH_4H_2PO_2} + \underset{\text{sodium hydroxide}}{NaOH} = \underset{\text{sodium hypophosphite}}{NaH_2PO_2} + \underset{\text{ammonia}}{NH_3} + \underset{\text{water}}{H_2O}$$

The hypophosphite is then oxidized with nitric acid, as explained above, and is estimated as phosphate.

Manganese Hypophosphite—The manganese is first removed from this salt by oxidation and precipitation as manganic hydroxide. An aliquot portion of the filtrate is then repeatedly evaporated with nitric acid to convert the hypophosphite radicle into phosphate. This is then estimated as phosphate, as described above.

Direct Titration with Silver Nitrate.

These assays involve precipitation with tenth-normal silver nitrate in the absence of free acid.

Oil of Bitter Almond—(Estimating the hydrocyanic acid content.) A weighed portion of the oil is treated with a mixture of magnesium sulphate, sodium hydroxide, and potassium chromate solutions which has already been titrated with tenth-normal silver nitrate until a permanent pink tint has been produced. The pink is promptly discharged by the oil of bitter almond and the mixture is titrated directly until the permanent reddish tint again appears. This titration is carried out in the presence of sodium hydroxide and magnesium sulphate, the former to fix the hydrocyanic acid as sodium cyanide and the latter to prevent hydrolysis. The potassium chromate serves as the indicator. The following equation explains the chemistry of the titration:

$$\underset{\text{sodium cyanide}}{NaCN} + \underset{\text{silver nitrate}}{AgNO_3} = \underset{\text{silver cyanide}}{AgCN} + \underset{\text{sodium nitrate}}{NaNO_3}$$

The reddish tint indicates the end of the reaction, since the first drop in excess forms a red precipitate of silver chromate when the indicator is present.

Titrations with Sodium Thiosulphate.

These assays require titration with standard sodium thiosulphate solution for the purpose of estimating free iodine.

The titration in all of the determinations of this type is based upon a reaction expressed as follows:

$$\underset{\text{sodium thiosulphate}}{2Na_2S_2O_3} + \underset{\text{iodine}}{I_2} = \underset{\text{sodium iodide}}{2NaI} + \underset{\text{sodium tetrathionate}}{Na_2S_4O_6}$$

The following substances are assayed by this means, some because of the presence of free iodine, others because of their ability under certain conditions to liberate iodine from potassium iodide.

Calcium Iodobehenas, Thymol Iodide, and Thyroxin—The iodine that is organically combined in each of these three materials is converted into potassium iodide by fusion with anhydrous potassium carbonate. This is then completely oxidized to potassium iodate by means of potassium permanganate. Potassium iodide and also free acid are then added to the mixture. Under these conditions all of the iodine is liberated from the iodate and a corresponding amount from the potassium iodide according to the following equation:

$$\underset{\text{potassium iodate}}{KIO_3} + \underset{\text{potassium iodide}}{5KI} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{potassium sulphate}}{3K_2SO_4} + \underset{\text{iodine}}{3I_2} + \underset{\text{water}}{3H_2O}$$

The liberated iodine is then estimated by means of tenth-normal sodium thiosulphate, starch being used as the indicator.

It will be observed from the above equation that only one-sixth of the total iodine liberated comes from the iodate, and, in turn, from the substance being assayed.

Thyroid—The assay for thyroid agrees in principle with those just explained but differs in certain details. First, a mixture of anhydrous sodium and potassium carbonates is used in the fusion; second, Labarraque's solution replaces potassium permanganate in oxidizing the iodides to iodate; third, phosphoric acid is used to liberate the iodine, and fourth, two-hundredth-normal sodium thiosulphate replaces the tenth-normal in estimating the free iodine.

Chlorinated Lime—This assay depends upon the liberation of the available chlorine from a given weight of material by treatment with acetic acid. The reaction that takes place is illustrated by the following equation:

$$\underset{\text{chlorinated lime}}{CaOCl_2} + \underset{\text{acetic acid}}{2HC_2H_3O_2} = \underset{\text{calcium acetate}}{Ca(C_2H_3O_2)_2} + \underset{\text{chlorine}}{Cl_2} + \underset{\text{water}}{H_2O}$$

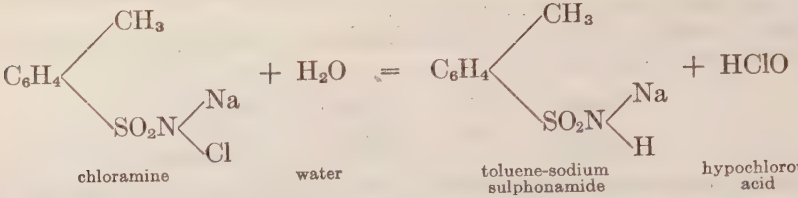
The free chlorine immediately reacts with a corresponding amount of potassium iodide, which was present in the mixture, displacing the iodine, atom for atom, as follows:

$$\underset{\text{chlorine}}{Cl_2} + \underset{\text{potassium iodide}}{2KI} = \underset{\text{potassium chloride}}{2KCl} + \underset{\text{iodine}}{I_2}$$

The free iodine is then estimated by titration with tenth-normal sodium thiosulphate, starch being used as the indicator. The number of cc. of volumetric solution used is calculated to available chlorine in the chlorinated lime by making use of the equivalent given in the official text.

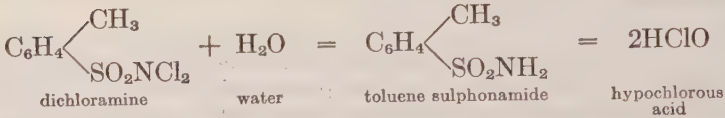
Chloramine and Dichloramine—In the case of Chloramine and Dichloramine the conditions are such as to restore hydrogen to the original amino-nitrogen

atom, the chlorine splitting off in the form of hypochlorous acid. This is a form of hydrolysis and is explained by the following equations:



chloramine — water — toluene-sodium sulphonamide — hypochlorous acid

and



dichloramine — water — toluene sulphonamide — hypochlorous acid

The hypochlorous acid then attacks potassium iodide, each molecule liberating two atoms of iodine from two molecules of potassium iodide, as follows:

$$2HClO + 4KI + 2HC_2H_3O_2 = 2KCl + 2KC_2H_3O_2 + I_4 + 2H_2O$$

hypochlorous acid — potassium iodide — acetic acid — potassium chloride — potassium acetate — iodine — water

The liberated iodine is then estimated with standard sodium thiosulphate in the usual manner.

Arsphenamine and Neoarsphenamine—In these assays the arsenic is oxidized from the trivalent to the pentavalent condition. It is then possible to displace iodine from the acidified solution of an iodide which is provided in the assay. The liberated iodine is then estimated with standard sodium thiosulphate and is calculated to per cent of arsenic.

Chromium Trioxide—Advantage is taken here of the ability of chromium trioxide, as an oxidizing agent, to liberate iodine from an iodide, in the presence of hydrochloric acid. The following equation illustrates the reaction that takes place:

$$2CrO_3 + 6KI + 12HCl = Cr_2Cl_6 + 6KCl + 3I_2 + 6H_2O$$

chromium trioxide — potassium iodide — hydrochloric acid — chromic chloride — potassium chloride — iodine — water

The liberated iodine is then titrated with tenth-normal sodium thiosulphate in the presence of starch indicator.

Copper Sulphate—When cupric sulphate is added to an iodide solution, the cupric iodide that would be expected to form breaks down immediately into cuprous iodide with the separation of one-half of its iodine. The following equation shows what takes place:

$$2CuSO_4 + 4KI = 2CuI + I_2 + 2K_2SO_4$$

cupric sulphate — potassium iodide — cuprous iodide — iodine — potassium sulphate

Acetic acid is also used as an accessory reagent. The free iodine is then estimated as described above and the calculation is made according to the directions in the text.

Ferric Chloride—The ability of an oxidizing agent to liberate iodine, quantitatively, from an iodide is again utilized in this assay. In the presence of hydrochloric acid, ferric chloride liberates iodine from potassium iodide according to the following equation:

$$\underset{\text{ferric chloride}}{2FeCl_3} + \underset{\text{potassium iodide}}{2KI} = \underset{\text{ferrous chloride}}{2FeCl_2} + \underset{\text{potassium chloride}}{2KCl} + \underset{\text{iodine}}{I_2}$$

The iodine is then ready to be estimated in the usual manner as already described.

Iron and Ammonium Citrate—Hydrochloric acid is added to a solution of the scaled salt to displace the weaker citric acid and to form chlorides of ferric iron and ammonium. The ferric chloride then displaces iodine from potassium iodide according to the equation given under ferric chloride.

Soluble Ferric Phosphate—This is another scaled salt which, after treatment with strong hydrochloric acid, is made to liberate iodine from potassium iodide. The reaction involved is essentially the same as already illustrated under the assay for ferric chloride.

Iodine—An aqueous solution of the iodine is prepared with the aid of potassium iodide. The diluted solution is then ready for titration with tenth-normal sodium thiosulphate, starch being used as the indicator. The type equation at the head of this group is the only one involved in this assay.

Sulphur Iodide—This compound is decomposed by the potassium iodide, the sulphur being precipitated and the free iodine remaining in solution. The liberated iodine is then estimated with sodium thiosulphate in the usual manner.

Bromine—In the presence of potassium iodide the bromine forms a corresponding amount of potassium bromide and liberates an equivalent amount of free iodine, as follows:

$$\underset{\text{bromine}}{Br_2} + \underset{\text{potassium iodide}}{2KI} = \underset{\text{potassium bromide}}{2KBr} + \underset{\text{iodine}}{I_2}$$

The liberated iodine is then estimated with sodium thiosulphate in the usual manner. Owing to the volatile character of the bromine the directions given in the text should be carefully followed.

Solution of Ferric Chloride—This solution is allowed to remain in contact with hydrochloric acid and potassium iodide for thirty minutes in a warm place. The mixture is cooled, diluted, and the free iodine estimated by titration with tenth-normal sodium thiosulphate, in the presence of starch which is added when nearly all of the iodine color has disappeared. The equation under ferric chloride explains this assay.

Solution of Iron and Ammonium Acetate—(For iron content.) This solution is first evaporated to dryness and ignited, redissolved in hydrochloric acid, and again evaporated to dryness with solution of hydrogen dioxide. This procedure eliminates the volatile and organic matter and oxidizes the iron to ferric chloride. After dissolving the residue in hydrochloric acid and adding potassium iodide, the liberated iodine is estimated by titration with standard sodium thiosulphate. The equation under ferric chloride illustrates the reaction involved.

Solution of Iron Tersulphate—Ferric salts, in general, have the power to liberate iodine from iodides. The equation that illustrates the reaction upon which this assay is based is as follows:

$$\underset{\text{ferric tersulphate}}{Fe_2(SO_4)_3} + \underset{\text{potassium iodide}}{2KI} = \underset{\text{ferrous sulphate}}{2FeSO_4} + \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{iodine}}{I_2}$$

The free iodine is then ready for titration with standard sodium thiosulphate solution.

Solution of Ferric Subsulphate—The principle upon which this assay is based is the same as in the assay of solution of iron tersulphate explained on page 1467. The ferric iron liberates iodine which is subsequently estimated by titration with sodium thiosulphate.

Ferric Glycerophosphate, Ferric Hypophosphite, Ferrous Lactate, Ferric Pyrophosphate, Albuminized Iron, Peptonized Iron, Solution of Ferric Citrate, Tincture of Ferric Chloride, Ethereal Tincture of Ferric Chloride, and Saccharated Ferric Oxide.

The assay of the foregoing substances depends upon their iron content. The solvents are first removed by evaporation and any organic matter that may be present is removed by ignition. Each of the above materials is then fully oxidized and treated with hydrochloric acid, whereby it is converted into ferric chloride. The chemistry involved, from this point, is identical with that which is explained in the description of the ferric chloride assay on page 1466.

Compound Solution of Iodine—(For iodine content.) After diluting with distilled water, this solution is ready for direct titration with tenth-normal sodium thiosulphate according to the type equation given at the head of this group.

Solution of Chlorinated Soda—The acetic acid which is added liberates the available chlorine from this solution as it does from chlorinated lime. The chlorine, in turn, displaces iodine from the potassium iodide, and the iodine is estimated in the usual way with standard sodium thiosulphate solution. See the explanation of the assay under chlorinated lime.

Surgical Solution of Chlorinated Soda—Here again the chlorine, which is present in loose combination, is rendered free by the action of acetic acid. The liberation of a corresponding amount of iodine from potassium iodide, and the subsequent estimation of the iodine with standard sodium thiosulphate solution, are explained under chlorinated lime, and by the type equation which heads this group.

Phenol—The first step in this assay involves the precipitation of tribromphenol by the action of tenth-normal bromine in the presence of hydrochloric acid. This is illustrated by the following equation:

$$\underset{\text{phenol}}{C_6H_5OH} + \underset{\text{bromine}}{3Br_2} = \underset{\text{tribromphenol}}{C_6H_2Br_3OH} + \underset{\text{hydrobromic acid}}{3HBr}$$

Potassium iodide is then quickly added and the excess of bromine promptly liberates iodine from this salt, atom for atom, as follows:

$$\underset{\text{potassium iodide}}{2KI} + \underset{\text{bromine}}{Br_2} = \underset{\text{potassium bromide}}{2KBr} + \underset{\text{iodine}}{I_2}$$

Chloroform is added to act as a solvent for the iodine and the mixture is then titrated in the usual manner with standard sodium thiosulphate solution.

Liquefied Phenol—The assay process is similar to the one just described for phenol.

Resorcinol—The assay process for resorcinol is practically the same as that already described for phenol. Tribromresorcinol is precipitated by tenth-normal bromine in the presence of hydrochloric acid according to the following equation:

$$\underset{\text{resorcinol}}{C_6H_4(OH)_2} + \underset{\text{bromine}}{3Br_2} = \underset{\text{tribromresorcinol}}{C_6HBr_3(OH)_2} + \underset{\text{hydrobromic acid}}{3HBr}$$

Tincture of Iodine and Stronger Tincture of Iodine—(For iodine content.) Dilution with distilled water is alone required to prepare these substances for the estimation of free iodine by means of tenth-normal sodium thiosulphate. The equation at the head of this group explains the reaction involved.

Red Lead Oxide—The red lead, being an oxidizing agent, liberates iodine from the acidified potassium iodide solution as follows:

$$\underset{\text{lead orthoplumbate}}{Pb_2PbO_4} + \underset{\text{potassium iodide}}{2KI} + \underset{\text{acetic acid}}{8HC_2H_3O_2} =$$

$$\underset{\text{lead acetate}}{3Pb(C_2H_3O_2)_2} + \underset{\text{potassium acetate}}{2KC_2H_3O_2} + \underset{\text{water}}{4H_2O} + \underset{\text{iodine}}{I_2}$$

The iodine is then estimated in the usual manner using tenth-normal sodium thiosulphate.

Sodium Arsenate and Exsiccated Sodium Arsenate—These salts are assayed by dissolving a weighed portion in water and heating the solution to 80° C. Hydrochloric acid and potassium iodide are then added and, after standing for some time, the solution is titrated for free iodine. The hydrochloric acid decomposes both salts, forming chlorides and liberating their respective acids. The arsenic acid in being reduced to arsenous acid liberates a corresponding amount of iodine. The reactions involved are expressed by the following equations:

$$\underset{\text{potassium iodide}}{2KI} + \underset{\text{sodium arsenate}}{Na_2HAsO_4} + \underset{\text{hydrochloric acid}}{4HCl} = \underset{\text{potassium chloride}}{2KCl} + \underset{\text{sodium chloride}}{2NaCl} + \underset{\text{hydriodic acid}}{2HI} + \underset{\text{arsenic acid}}{H_3AsO_4}$$

then

$$\underset{\text{arsenic acid}}{H_3AsO_4} + \underset{\text{hydriodic acid}}{2HI} = \underset{\text{arsenous acid}}{H_3AsO_3} + \underset{\text{water}}{H_2O} + \underset{\text{iodine}}{I_2}$$

The liberated iodine is then titrated with tenth-normal sodium thiosulphate.

Solution of Sodium Arsenate and Diluted Solution of Sodium Arsenate—The above description for the assay of sodium arsenate applies equally to the estimation of this salt in the foregoing solutions.

Acetone—This assay is based upon the familiar iodoform reaction. The titration is in reality a residual one in which two standard solutions are employed. An excess of tenth-normal iodine is brought into contact with the acetone in the presence of an alkali, whereby iodoform is produced according to the following equations:

$$\underset{\text{acetone}}{CH_3COCH_3} + \underset{\text{iodine}}{3I_2} = \underset{\text{tri-iodo-acetone}}{CI_3COCH_3} + \underset{\text{hydriodic acid}}{3HI}$$

then

$$\underset{\text{tri-iodo-acetone}}{CI_3COCH_3} + \underset{\text{hydriodic acid}}{3HI} + \underset{\text{sodium hydroxide}}{4NaOH} = \underset{\text{iodoform}}{CHI_3} + \underset{\text{sodium iodide}}{3NaI} + \underset{\text{water}}{3H_2O} + \underset{\text{sodium acetate}}{CH_3COONa}$$

Hydrochloric acid is then added to liberate the excess of iodine from combination with the alkali and the mixture is ready for titration with standard thiosulphate solution. A blank determination is conducted, omitting the acetone, and by comparing the two determinations the amount of iodine consumed by the acetone can be calculated. Starch test solution is used as the indicator in each of the above determinations.

In the presence of considerable iodine, starch as an indicator forms bluish-black lumps that are difficult to dissolve, hence the indicator should not be added until nearly all of the iodine color has been discharged. The remaining iodine can easily be detected on adding the starch because of the pronounced blue color which appears, even in great dilution. The titration of iodine must always be carried out in cold liquids.

It will be observed that this method of analysis can be applied to oxidizing agents as a class because of their ability to liberate iodine in an acidulated solution of an iodide.

Direct Titration with Iodine.

The assays in this group involve the direct oxidation of a substance by means of tenth-normal iodine.

Sodium Thiosulphate—Just as iodine can be estimated with tenth-normal sodium thiosulphate so can sodium thiosulphate be estimated with tenth-normal iodine. The equation to illustrate this reaction is the one given at the head of the preceding group on page 1465. Starch is again used as the indicator and the appearance of a permanent blue color is evidence of the completion of the titration.

Antimony and Potassium Tartrate—A cold, saturated solution of sodium bicarbonate is added to an aqueous solution of this salt, starch indicator is added, and the mixture is titrated with tenth-normal iodine until a permanent blue color appears. This reaction is based upon the oxidation of the tartar emetic to sodium metantimonate, as expressed by the following equation:

$$\underset{\text{tartar emetic}}{2KSbO(C_4H_4O_6)} + \underset{\text{iodine}}{2I_2} + \underset{\text{sodium bicarbonate}}{8NaHCO_3} = \underset{\text{sodium metantimonate}}{2NaSbO_3} + \underset{\text{sodium iodide}}{4NaI} +$$

$$\underset{\text{potassium and sodium tartrate}}{2KNaC_4H_4O_6} + \underset{\text{carbon dioxide}}{8CO_2} + \underset{\text{water}}{4H_2O}$$

The equivalent weight of tartar emetic for each cc. of tenth-normal iodine consumed in the titration, is given in the official text.

Arsenic Trioxide—This compound is dissolved in boiling distilled water with the aid of sodium hydroxide T.S. and is thereby converted into sodium arsenite according to the following equation:

$$\underset{\text{arsenic trioxide}}{As_2O_3} + \underset{\text{sodium hydroxide}}{6NaOH} = \underset{\text{sodium arsenite}}{2Na_3AsO_3} + \underset{\text{water}}{3H_2O}$$

The solution is neutralized with sulphuric acid to prevent the iodine from reacting with the excess of free alkali. Sodium bicarbonate is then added to the mixture and tenth-normal iodine introduced until a permanent blue color appears, using starch as the indicator. The sodium arsenite is thereby oxidized to arsenate as follows:

$$\underset{\text{sodium arsenite}}{Na_3AsO_3} + \underset{\text{iodine}}{I_2} + \underset{\text{water}}{H_2O} = \underset{\text{sodium arsenate}}{Na_3AsO_4} + \underset{\text{hydriodic acid}}{2HI}$$

The sodium bicarbonate reacts with the hydriodic acid as rapidly as it is formed and thus enables the reaction to go entirely in the one direction.

Antimony Oxide—An aqueous solution of tartaric acid is used for the purpose of dissolving the antimony oxide. The acid is nearly neutralized with sodium carbonate solution, the antimony is then oxidized to the pentavalent condition

by titrating with tenth-normal iodine in the presence of an excess of sodium bicarbonate, using starch as the indicator. The titration with iodine V.S. should be carried out immediately after adding the sodium bicarbonate solution to avoid the separation of an insoluble basic salt of the antimony. The chemical principles involved in this assay are similar to those outlined in the foregoing description of the assay for arsenic trioxide.

Solution of Arsenous Acid—Since the arsenic compound is already in solution all that needs to be done is to dilute with distilled water, add the excess of sodium bicarbonate and the starch indicator, and the mixture is ready for titration with tenth-normal iodine. The reaction is illustrated by the following equation:

$$\underset{\text{arsenous acid}}{H_3AsO_3} + \underset{\text{iodine}}{I_2} + \underset{\text{water}}{H_2O} = \underset{\text{arsenic acid}}{H_3AsO_4} + \underset{\text{hydriodic acid}}{2HI}$$

The sodium bicarbonate neutralizes the free acid that forms and thereby prevents the reaction from going in the reverse direction.

Solution of Arsenous and Mercuric Iodide—(For arsenous iodide content.) As in the above cases the arsenic is oxidized from the trivalent to the pentavalent form at the expense of tenth-normal iodine. Sodium bicarbonate is used in excess for reasons explained above, and starch is used as the indicator

Solution of Potassium Arsenite—The indefinite alkalinity of this solution is first removed by making the solution faintly acid with diluted hydrochloric acid. An excess of sodium bicarbonate is then added and the liquid titrated with tenth-normal iodine, starch being used as the indicator. The following equation illustrates the reaction:

$$\underset{\text{potassium metarsenite}}{KAsO_2} + \underset{\text{iodine}}{I_2} + \underset{\text{water}}{H_2O} = \underset{\text{potassium metarsenate}}{KAsO_3} + \underset{\text{hydriodic acid}}{2HI}$$

The purpose of the added sodium bicarbonate is explained under solution of arsenous acid, see above.

Residual Titrations with an Excess of Iodine.

These assays require residual titrations involving the use of an excess of tenth-normal iodine, and the subsequent estimation of the residual iodine with tenth-normal sodium thiosulphate.

Mild Mercurous Chloride—The prolonged contact, with agitation, of the mild mercurous chloride with tenth-normal iodine and potassium iodide, converts it into mercurous iodide and subsequently into mercuric iodide which is soluble in the presence of the potassium iodide. The reactions involved in these changes are as follows:

$$\underset{\text{mercurous chloride}}{HgCl} + \underset{\text{potassium iodide}}{KI} = \underset{\text{mercurous iodide}}{HgI} + \underset{\text{potassium chloride}}{KCl}$$

The iodine then oxidizes the mercurous iodide to mercuric iodide as follows:

$$\underset{\text{mercurous iodide}}{2HgI} + \underset{\text{iodine}}{I_2} = \underset{\text{mercuric iodide}}{2HgI_2}$$

The residual iodine is then estimated by titration with tenth-normal sodium thiosulphate in the usual manner.

Yellow Iodide of Mercury—The details for this assay process are practically the same as those described under mild mercurous chloride except that the first equation is not involved, since mercurous iodide is the starting point in the determination.

Titrations with Potassium Dichromate.

These assays require oxidation by direct titration with tenth-normal potassium dichromate.

Saccharated Ferrous Carbonate—This is first dissolved in diluted sulphuric acid and the solution diluted with distilled water. The volumetric solution is carefully added until a drop of the mixture, when removed and brought into contact with a drop of potassium ferricyanide test solution, ceases to give a blue color. The cause of this blue color is the formation of ferrous ferricyanide, or Turnbull's blue, and its failure to appear is evidence that all of the iron has been oxidized to the ferric condition. The reaction that takes place between the ferrous carbonate and the sulphuric acid, in which it is dissolved, is shown by the following equation:

$$\underset{\text{ferrous carbonate}}{FeCO_3} + \underset{\text{sulphuric acid}}{H_2SO_4} = \underset{\text{ferrous sulphate}}{FeSO_4} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

The subsequent reaction between the ferrous sulphate and tenth-normal potassium dichromate is expressed as follows:

$$\underset{\text{ferrous sulphate}}{6FeSO_4} + \underset{\text{potassium dichromate}}{K_2Cr_2O_7} + \underset{\text{sulphuric acid}}{7H_2SO_4} = \underset{\text{ferric sulphate}}{3Fe_2(SO_4)_3} + \underset{\text{chromic sulphate}}{Cr_2(SO_4)_3} + \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{water}}{7H_2O}$$

The number of cc. of tenth-normal potassium dichromate is calculated to ferrous carbonate by applying the factor given in the official text.

Pills of Ferrous Carbonate and Mass of Ferrous Carbonate—These preparations are dissolved in diluted sulphuric acid and the method for estimating the ferrous carbonate is identical with that already described above for saccharated ferrous carbonate.

Residual Titrations Using an Excess of Oxalic Acid.

These assays require the precipitation of insoluble oxalates with tenth-normal oxalic acid, in excess, and the estimation of residual oxalic acid by titration with tenth-normal potassium permanganate, in the presence of diluted sulphuric acid.

When oxalic acid is determined by means of potassium permanganate or vice versa, the reaction involved is expressed by the following equation:

$$\underset{\text{oxalic acid}}{5H_2C_2O_4} + \underset{\text{potassium permanganate}}{K_2Mn_2O_8} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{manganous sulphate}}{2MnSO_4} + \underset{\text{carbon dioxide}}{10CO_2} + \underset{\text{water}}{8H_2O}$$

This reaction is best conducted at a steaming, but not a boiling, temperature. Potassium permanganate serves as its own indicator.

The assay methods for the following belong to this group.

Precipitated Calcium Carbonate and Prepared Chalk—These are first converted into calcium chloride by dissolving in diluted hydrochloric acid, thus:

$$\underset{\text{calcium carbonate}}{CaCO_3} + \underset{\text{hydrochloric acid}}{2HCl} = \underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{water}}{H_2O}$$

After boiling to remove the carbon dioxide, this solution is treated with an excess of tenth-normal oxalic acid and the mixture made alkaline with ammonia to insure complete precipitation of the calcium oxalate. The following equation illustrates the reaction:

$$\underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{oxalic acid}}{H_2C_2O_4} = \underset{\text{calcium oxalate}}{CaC_2O_4} + \underset{\text{hydrochloric acid}}{2HCl}$$

The excess of ammonia promptly takes care of the hydrochloric acid that forms, yielding ammonium chloride. The mixture is then allowed to stand in a warm place. After diluting to a definite volume, and agitating, it is filtered and an aliquot portion of the filtrate, to which diluted sulphuric acid has been added, is titrated with standard potassium permanganate solution until a permanent pink color appears.

Calx—The lime is freshly ignited and the residue converted into calcium chloride by dissolving it in diluted hydrochloric acid as follows:

$$\underset{\text{calcium oxide (lime)}}{CaO} + \underset{\text{hydrochloric acid}}{2HCl} = \underset{\text{calcium chloride}}{CaCl_2} + \underset{\text{water}}{H_2O}$$

From this point the procedure is the same as described above for precipitated calcium carbonate.

Solution of Lead Subacetate and Diluted Solution of Lead Subacetate—When these solutions are treated with an excess of standard oxalic acid solution, the insoluble lead oxalate is precipitated according to the following equation:

$$\underset{\text{lead subacetate}}{Pb_2O(CH_3COO)_2} + \underset{\text{oxalic acid}}{2H_2C_2O_4} = \underset{\text{lead oxalate}}{2PbC_2O_4} + \underset{\text{acetic acid}}{2CH_3COOH} + \underset{\text{water}}{H_2O}$$

After diluting the mixture to a definite volume and thorough agitation, it is filtered and an aliquot portion of the filtrate, to which diluted sulphuric acid has been added, is titrated with standard potassium permanganate solution until a permanent pink color appears.

Lead Acetate—A definite weight of the salt is dissolved in recently boiled distilled water. The addition of tenth-normal oxalic acid to an aliquot portion of this solution precipitates lead oxalate as follows:

$$\underset{\text{lead acetate}}{Pb(C_2H_3O_2)_2} + \underset{\text{oxalic acid}}{H_2C_2O_4} = \underset{\text{lead oxalate}}{PbC_2O_4} + \underset{\text{acetic acid}}{2HC_2H_3O_2}$$

The remaining part of the assay is practically the same as already described for solution of lead subacetate (see above).

Lead Monoxide—This oxide is converted into lead acetate by dissolving it in a solution of glacial acetic acid, according to the following equation:

$$\underset{\text{lead monoxide}}{PbO} + \underset{\text{glacial acetic acid}}{2HC_2H_3O_2} = \underset{\text{lead acetate}}{Pb(C_2H_3O_2)_2} + \underset{\text{water}}{H_2O}$$

From this point the procedure is the same as has been described above under solution of lead subacetate.

Direct Titrations with Potassium Permanganate.

These assays require direct titrations involving oxidation by means of tenth-normal potassium permanganate.

Ferrous Sulphate—A solution of the ferrous sulphate in diluted sulphuric acid is oxidized by standard potassium permanganate solution according to the following equation:

$$\underset{\text{ferrous sulphate}}{10FeSO_4} + \underset{\text{potassium permanganate}}{K_2Mn_2O_8} + \underset{\text{sulphuric acid}}{8H_2SO_4} = \underset{\text{ferric sulphate}}{5Fe_2(SO_4)_3} + \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{manganous sulphate}}{2MnSO_4} + \underset{\text{water}}{8H_2O}$$

The end of the reaction is shown by the appearance of a permanent pink color which signifies that the permanganate is no longer being reduced.

Exsiccated Ferrous Sulphate—The assay process for this salt is identical with the one just described for ferrous sulphate.

Reduced Iron—Mercuric chloride solution converts the iron into ferrous chloride and metallic mercury is displaced. The ferrous chloride is then oxidized by standard potassium permanganate and the volume required is calculated to metallic iron.

Solution of Hydrogen Dioxide—A definite weight of this solution is diluted with distilled water and treated with diluted sulphuric acid, which serves as an accessory reagent. The mixture is then titrated with tenth-normal potassium permanganate until a permanent pink color appears. The reaction that takes place is illustrated by the following equation:

$$\underset{\text{hydrogen dioxide}}{5H_2O_2} + \underset{\text{potassium permanganate}}{K_2Mn_2O_8} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{manganous sulphate}}{2MnSO_4} + \underset{\text{water}}{8H_2O} + \underset{\text{oxygen}}{5O_2}$$

NOTE—It will be observed that only half of the evolved oxygen comes from the hydrogen dioxide, the other half coming from the potassium permanganate. Due consideration should be given to this if the volume of the evolved gas is being measured.

Sodium Perborate—The conditions here are the same as those provided in the assay of solution of hydrogen dioxide. Each molecule of sodium perborate undergoes hydrolytic decomposition, yielding one molecule of hydrogen dioxide as follows:

$$\underset{\text{sodium perborate}}{NaBO_3 \cdot 4H_2O} + \underset{\text{water}}{H_2O} = \underset{\text{hydrogen dioxide}}{H_2O_2} + \underset{\text{sodium metaborate}}{NaBO_2} + \underset{\text{water}}{4H_2O}$$

The permanganate titration that follows is explained in the above description for the assay of hydrogen dioxide.

No indicator is required in the titration of substances in this group since the potassium permanganate itself supplies the necessary evidence that the reaction is complete by producing a permanent pink color.

Residual Titration with Excess of Potassium Permanganate.

The substances assayed by this method require oxidation by means of tenth-normal potassium permanganate and the subsequent titration of the residual permanganate with tenth-normal oxalic acid.

Sodium Nitrite—An aqueous solution of this salt is delivered, by means of a pipette, into an excess of acidified permanganate solution, in such a way as to prevent the escape of nitrous acid. The reaction is expressed as follows:

$$\underset{\text{sodium nitrite}}{5NaNO_2} + \underset{\text{potassium permanganate}}{K_2Mn_2O_8} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{sodium nitrate}}{5NaNO_3} + \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{manganous sulphate}}{2MnSO_4} + \underset{\text{water}}{3H_2O}$$

The liquid is warmed and allowed to stand. The excess of permanganate is then estimated by titration with tenth-normal oxalic acid. The equation that illustrates this reaction appears on page 1472.

Titration of an Excess of Ferrous Sulphate with Potassium Permanganate.

The substances assayed by this method require reduction by means of acidulated ferrous sulphate test solution and estimation of the residual ferrous sulphate by titrating with tenth-normal potassium permanganate.

Potassium Chlorate—This salt is reduced to potassium chloride at the expense of a corresponding amount of ferrous sulphate, according to the following equation:

$$\underset{\text{potassium chlorate}}{KClO_3} + \underset{\text{ferrous sulphate}}{6FeSO_4} + \underset{\text{sulphuric acid}}{3H_2SO_4} = \underset{\text{potassium chloride}}{KCl} + \underset{\text{ferric sulphate}}{3Fe_2(SO_4)_3} + \underset{\text{water}}{3H_2O}$$

After boiling the mixture for ten minutes it is cooled and the unused ferrous sulphate is estimated by titration with tenth-normal potassium permanganate, in the presence of manganous sulphate T.S. This reaction is explained by the equation on page 1474. A blank test is conducted by titrating an equal volume of the same acidified ferrous sulphate solution but omitting the potassium chlorate. The amount of tenth-normal potassium permanganate, equivalent to the potassium chlorate, can then be calculated by noting the difference in the amounts of standard solution required in the two titrations.

Titration with Oxalic Acid, Used as a Reducing Agent.

The method of assay is dependent upon reduction by means of tenth-normal oxalic acid.

Potassium Permanganate—An aqueous solution of this salt is acidified with sulphuric acid, warmed to about 80° C., and titrated with the standard oxalic acid solution until the color of the permanganate is completely discharged. The equation which explains this reaction will be found on page 1472.

GRAVIMETRIC METHODS OF ANALYSIS

The assay methods of this type generally involve the separation and weighing of a substance of definite composition. The weight of this substance is then calculated back to a corresponding weight of the material being determined. These methods are also arranged in groups according to the points of resemblance or difference, which appear in the various procedures. The classification adopted is as follows:

1. Methods involving evaporation of the solvent.
2. Decomposition by direct heat and weighing the residue.
3. Precipitation and subsequent weighing of the precipitate.
4. Precipitation followed by ignition and decomposition of the precipitate.
5. Miscellaneous gravimetric processes.

The Evaporation of the Solvent.

Determinations by this method are based upon the removal of the solvent by evaporation and noting the constant weight of the residue.

Spirit of Glyceryl Trinitrate—Considerable caution is required in handling nitroglycerin, hence the alcohol is allowed to evaporate spontaneously and the residue is dried to constant weight over concentrated sulphuric acid.

Compound Solution of Iodine—(For potassium iodide content.) The water and the iodine are removed from this solution with the aid of heat on a water bath. More distilled water may be added from time to time to assist in removing the last traces of iodine. When a constant weight of white residue is obtained, it should respond to the identity tests for potassium iodide.

Tincture of Iodine—(For potassium iodide content.) The alcohol and the iodine are removed by evaporation with the aid of a water bath. Small portions of distilled water may be added from time to time in order to remove the last traces of iodine which is betrayed by its color. When a white residue of constant weight is obtained, it should respond to the identity tests for potassium iodide.

In the following group of assays an active principle is liberated by means of an acid or an alkali and separated by the use of successive portions of an immiscible solvent, the solvent being subsequently removed by evaporation:

Barbital-Sodium—This compound is first decomposed by diluted hydrochloric acid which combines with the sodium to form sodium chloride. The liberated barbital is then extracted from the mixture with successive portions of ether. The ether is evaporated from the combined extractions and the residue is dried at 100° C. and weighed.

Citrated Caffeine—This substance is first dissolved in hot distilled water and decomposed by sodium hydroxide test solution which reacts to form sodium citrate and free caffeine. The liberated caffeine is then extracted from the mixture with successive portions of chloroform. The chloroform is removed from the combined extractions by evaporation on a water bath and the caffeine is dried to constant weight at a temperature not above 80° C.

Caffeine Sodio-Benzoate and Caffeine Sodio-Salicylate—(For caffeine content.) The description of these assays is essentially the same as the one just given for citrated caffeine.

Quinine and Urea Hydrochloride—The quinine is liberated from an aqueous solution of this compound by the addition of ammonia water. The alkaloid is then extracted from the mixture with successive portions of chloroform. The chloroform is removed from the combined extractions by evaporation on a water bath and, after redissolving in ether and evaporating, the residue of quinine is dried and weighed. The weight of quinine found is then calculated to indicate the weight of quinine and urea hydrochloride originally present.

Quinine Tannate—The quinine is liberated from an aqueous solution of this salt by treatment with an excess of ammonia water. Successive portions of ether are then used to extract the quinine from the mixture, the ether is evaporated from the combined ethereal liquids, and the residue of quinine dried and weighed.

Storax—(For cinnamic acid content.) The esters are saponified by prolonged boiling with alcoholic potassium hydroxide, under a reflux condenser. The excess of free alkali is then carefully neutralized with sulphuric acid, in the presence of phenolphthalein. After removing the alcohol by evaporation, distilled water is added to obtain the potassium cinnamate in aqueous solution and foreign matter is removed by extraction with ether. The potassium cinnamate in the aqueous solution is then decomposed by adding an excess of diluted sulphuric

acid which liberates cinnamic acid and forms potassium sulphate. The cinnamic acid is next extracted from this mixture with successive portions of ether, the ether is distilled off, and the cinnamic acid dissolved in boiling distilled water. This solution is filtered while hot and the crystals of cinnamic acid are allowed to separate from the filtrate. Finally crystals are collected on a filter with the aid of suction, dried, and weighed.

Theobromine Sodio-Salicylate—(For theobromine content.) The theobromine is liberated by careful titration with normal hydrochloric acid, in the presence of phenolphthalein as the indicator, a trace of ammonia water being added, if necessary, to render the mixture slightly alkaline. Under these conditions the mixture is allowed to stand with occasional stirring. The separated theobromine is then collected on a weighed filter and washed with successive portions of ice-cold distilled water. The filter and precipitate are finally dried at 100° C. and weighed.

Decomposition by Applying Direct Heat.

These determinations involve the direct ignition of a substance to obtain the weight of a residue in the form of oxide.

Bismuth Subcarbonate, Bismuth Subgallate, Bismuth Subnitrate, and *Bismuth Subsalicylate*—All of these compounds of bismuth are basic salts and are of slightly variable composition. Each one, however, is required to yield, when ignited to constant weight, a given percentage of bismuth trioxide (Bi_2O_3). It is not difficult to expel the volatile matter from the subcarbonate and the subnitrate, but in the other two salts a slight modification of the procedure is necessary, as the residue from the ignition of the subgallate, or the subsalicylate, is cooled, treated with nitric acid, and re-ignited. This is done for the purpose of oxidizing any organic matter or carbon, and to prevent the reduction of the bismuth trioxide to metallic bismuth which would vitiate the results of the assay. *Caution—Metallic bismuth readily forms fusible alloys with metals, hence bismuth salts should not be ignited in platinum crucibles.*

Bismuth Magma—This is evaporated to dryness and the residue ignited to bismuth oxide in the usual manner.

Glycerite of Bismuth—The bismuth is first precipitated as sulphide by using hydrogen sulphide in the presence of free hydrochloric acid. This is then converted into nitrate, by solution in nitric acid. The bismuth is subsequently precipitated from this solution as basic carbonate which is washed and ignited to bismuth oxide in the usual manner.

Precipitation Followed by Ignition.

This method applies to substances which are estimated, by ignition, as an oxide, after first precipitating them in some other form.

Alum—Alum is first dissolved in distilled water containing ammonium chloride, which serves as an accessory reagent by making the subsequent precipitation more complete. Ammonia water is added in slight excess to the boiling solution and aluminum hydroxide is precipitated. Using ammonia-alum as an example, the reaction is expressed as follows:

$$\underset{\text{aluminum and ammonium sulphate}}{Al(NH_4)(SO_4)_2.12H_2O} + \underset{\text{ammonium hydroxide}}{3NH_4OH} = \underset{\text{aluminum hydroxide}}{Al(OH)_3} + \underset{\text{ammonium sulphate}}{2(NH_4)_2SO_4} + \underset{\text{water}}{12H_2O}$$

The precipitated aluminum hydroxide is then collected on a filter, washed, dried, and ignited. In the ignition the hydroxide is converted into aluminum trioxide according to the following equation:

$$\underset{\text{aluminum hydroxide}}{2Al(OH)_3} = \underset{\text{aluminum oxide}}{Al_2O_3} + \underset{\text{water}}{3H_2O}$$

The ignition is continued until the weight of the residue becomes constant.

Exsiccated Alum—The assay for exsiccated alum is essentially identical with that given above for alum.

Aluminum Chloride and Aluminum Sulphate—The equations involved in the actual precipitations are expressed as follows:

$$\underset{\text{aluminum chloride}}{AlCl_3} + \underset{\text{ammonium hydroxide}}{3NH_4OH} = \underset{\text{aluminum hydroxide}}{Al(OH)_3} + \underset{\text{ammonium chloride}}{3NH_4Cl}$$

$$\underset{\text{aluminum sulphate}}{Al_2(SO_4)_3} + \underset{\text{ammonium hydroxide}}{6NH_4OH} = \underset{\text{aluminum hydroxide}}{2Al(OH)_3} + \underset{\text{ammonium sulphate}}{3(NH_4)_2SO_4}$$

The remaining parts of these assays are identical with the description given above for the assay of alum.

Solution of Aluminum Acetate and Solution of Aluminum Subacetate—Aluminum hydroxide is precipitated from these solutions by means of ammonia water, in the presence of ammonium chloride. This is then separated by filtration, washed, dried, and ignited to aluminum oxide, as described under the above assay for alum.

Calcium Glycerophosphate—This salt is dissolved in distilled water with the aid of acetic acid. The mixture is heated to boiling and treated with an excess of ammonium oxalate T.S., which causes the precipitation of calcium oxalate. This precipitate is collected on a filter, washed, dried, and ignited to constant weight. The decomposition during this ignition is illustrated by the following equation:

$$\underset{\text{calcium oxalate}}{CaC_2O_4} = \underset{\text{calcium oxide}}{CaO} + \underset{\text{carbon dioxide}}{CO_2} + \underset{\text{carbon monoxide}}{CO}$$

NOTE—Calcium glycerophosphate may also be determined gravimetrically by direct ignition to calcium pyrophosphate. The decomposition is expressed as follows:

$$\underset{\text{calcium glycerophosphate}}{2C_3H_5(OH)_2PO_4Ca} + \underset{\text{oxygen (air)}}{7O_2} = \underset{\text{calcium pyrophosphate}}{Ca_2P_2O_7} + \underset{\text{carbon dioxide}}{6CO_2} + \underset{\text{water}}{7H_2O}$$

Zinc Acetate—An aqueous solution of this salt is made alkaline with ammonia water, warmed, and then the zinc is precipitated as sulphide, by adding an excess of ammonium sulphide T.S. The reaction is expressed as follows:

$$\underset{\text{zinc acetate}}{Zn(C_2H_3O_2)_2} + \underset{\text{ammonium sulphide}}{(NH_4)_2S} = \underset{\text{zinc sulphide}}{ZnS} + \underset{\text{ammonium acetate}}{2NH_4C_2H_3O_2}$$

The precipitate is collected on a filter, washed, and dissolved in hot, diluted nitric acid, whereby the zinc sulphide is converted into nitrate, as follows:

$$\underset{\text{zinc sulphide}}{ZnS} + \underset{\text{nitric acid}}{2HNO_3} = \underset{\text{zinc nitrate}}{Zn(NO_3)_2} + \underset{\text{hydrogen sulphide}}{H_2S}$$

The solution of zinc nitrate is then evaporated to dryness, ignited to constant weight, and weighed as zinc oxide, the final decomposition being expressed as follows:

$$\underset{\text{zinc nitrate}}{Zn(NO_3)_2} = \underset{\substack{\text{zinc}\\\text{oxide}}}{ZnO} + \underset{\substack{\text{nitrogen}\\\text{tetra-oxide}}}{2NO_2} + \underset{\text{oxygen}}{O}$$

Zinc Sulphate and Zinc Phenolsulphonate—The descriptions of these assays are identical with that given above for zinc acetate.

Gravimetric Estimation as Sulphide.

Determinations of this type are based upon the separation and the weighing of an insoluble sulphide.

Corrosive Mercuric Chloride—The mercury is completely precipitated from an acidified solution of this salt by means of hydrogen sulphide, the reaction being expressed as follows:

$$\underset{\substack{\text{mercuric}\\\text{chloride}}}{HgCl_2} + \underset{\substack{\text{hydrogen}\\\text{sulphide}}}{H_2S} = \underset{\substack{\text{mercuric}\\\text{sulphide}}}{HgS} + \underset{\substack{\text{hydrochloric}\\\text{acid}}}{2HCl}$$

The mercuric sulphide is then collected on counterbalanced filters and washed successively with distilled water, alcohol, and with carbon tetrachloride to remove free sulphur. It is then dried at 110° C. until of constant weight. The observed weight is then calculated to a corresponding weight of mercuric chloride, by applying the factor given in the U. S. P. text.

Ammoniated Mercury—This compound is converted into mercuric chloride by dissolving it in a warm solution of hydrochloric acid, according to the following equation:

$$\underset{\substack{\text{ammoniated}\\\text{mercury}}}{HgNH_2Cl} + \underset{\substack{\text{hydrochloric}\\\text{acid}}}{2HCl} = \underset{\substack{\text{mercuric}\\\text{chloride}}}{HgCl_2} + \underset{\substack{\text{ammonium}\\\text{chloride}}}{NH_4Cl}$$

From this point the assay is similar to that just given above for mercuric chloride.

Poison Tablets of Corrosive Mercuric Chloride—An aqueous solution of one of the tablets is used in the determination, a single tablet being taken to check the individual content of corrosive mercuric chloride. The assay is identical with that explained above under corrosive mercuric chloride.

The Precipitation of Barium Sulphate.

The following assays involve the precipitation of barium sulphate and its subsequent ignition to constant weight:

Sodium Sulphate—A hot, acidulated solution of this salt is treated with an excess of barium chloride T.S. whereby the sulphate reacts with a corresponding amount of barium as follows:

$$\underset{\substack{\text{sodium}\\\text{sulphate}}}{Na_2SO_4} + \underset{\substack{\text{barium}\\\text{chloride}}}{BaCl_2} = \underset{\substack{\text{barium}\\\text{sulphate}}}{BaSO_4} + \underset{\substack{\text{sodium}\\\text{chloride}}}{2NaCl}$$

The barium sulphate is then collected on a filter, washed, dried, and ignited to constant weight, the weight being calculated to sodium sulphate by applying the factor given in the U. S. P. text.

Potassium Sulphate—The description of this assay is identical with the one given above for sodium sulphate.

Sulphonated Bitumen—(For ammonium sulphate content.) After thoroughly washing the sulphonated bitumen with alcohol and a mixture of alcohol and ether, neither of which dissolve the ammonium sulphate, the residue is dried, cooled, and washed with warm acidulated water. The ammonium sulphate is determined in the aqueous filtrate by means of barium chloride solution, as described on page 1479 in the assay of sodium sulphate.

Sublimed Sulphur, Precipitated Sulphur, and Washed Sulphur—Each of the forms of sulphur is first converted into soluble potassium polysulphides by boiling with potassium hydroxide. The sulphides are then oxidized to potassium sulphate by means of hydrogen dioxide. The following is a typical equation showing the oxidation of one of these polysulphides:

$$\underset{\text{potassium sulphide}}{K_2S} + \underset{\text{hydrogen dioxide}}{4H_2O_2} = \underset{\text{potassium sulphate}}{K_2SO_4} + \underset{\text{water}}{4H_2O}$$

The solution containing potassium sulphate is then acidified with hydrochloric acid and treated, while hot, with an excess of barium chloride T.S., whereby the original sulphur is completely precipitated as barium sulphate. This is then filtered off, washed, dried, and ignited to constant weight.

Sulphonated Bitumen—(For sulphur content.) A mixture of the sulphonated bitumen and sodium peroxide is ignited by means of a red-hot iron wire, in a nickel crucible, and the fused mass is then boiled with acidulated distilled water. The sulphur is thus converted, by means of this fusion and oxidation, into sodium sulphate. This is then precipitated as barium sulphate by means of barium chloride solution, as explained in the above assay for sodium sulphate. The weight of barium sulphate found is then calculated to sulphur by using the corresponding molecular and atomic weights.

Gravimetric Estimation as Lithium Sulphate.

Lithium Benzoate—Weighed portions of the dried powder, and of ammonium sulphate, are mixed and ignited in a crucible until the weight is constant. Double decomposition takes place as follows:

$$\underset{\text{lithium benzoate}}{2LiC_7H_5O_2} + \underset{\text{ammonium sulphate}}{(NH_4)_2SO_4} = \underset{\text{lithium sulphate}}{Li_2SO_4} + \underset{\text{ammonium benzoate}}{2(NH_4)C_7H_5O_2}$$

The residue, after ignition, consists only of lithium sulphate, the ammonium benzoate having been removed by reason of its volatile character. The weight of lithium sulphate found is then calculated to lithium benzoate by making use of the factor given in the N. F. text.

The Gravimetric Estimation of Magnesium.

These assays require the precipitation of magnesium-ammonium phosphate and the subsequent weighing of the ignited residue of magnesium pyrophosphate.

Magnesium Sulphate—The addition of the sodium phosphate T.S. and ammonia T.S. causes the precipitation of the magnesium as magnesium-ammonium phosphate. The reaction is expressed as follows:

$$\underset{\text{magnesium sulphate}}{MgSO_4} + \underset{\text{sodium phosphate}}{Na_2HPO_4} + \underset{\text{ammonia}}{NH_3} = \underset{\text{magnesium-ammonium phosphate}}{MgNH_4PO_4} + \underset{\text{sodium sulphate}}{Na_2SO_4}$$

The precipitate is then filtered, washed, dried, and ignited to constant weight. During the ignition, the magnesium-ammonium phosphate is converted into magnesium pyrophosphate by the loss of ammonia and water, according to the following equation:

$$\underset{\text{magnesium-ammonium phosphate}}{2MgNH_4PO_4} = \underset{\text{magnesium pyrophosphate}}{Mg_2P_2O_7} + \underset{\text{ammonia}}{2NH_3} + \underset{\text{water}}{H_2O}$$

The weight of the residue is then calculated to magnesium sulphate, using the factor given in the U. S. P. text.

Solution of Magnesium Citrate—This solution is first evaporated to dryness and the residue ignited to convert the magnesium citrate into magnesium oxide and to remove most of the carbonaceous matter. Each molecule of magnesium citrate yields three molecules of magnesium oxide, as follows:

$$\underset{\text{magnesium citrate}}{2Mg_3(C_6H_5O_7)_3} + \underset{\text{oxygen}}{51O} = \underset{\text{magnesium oxide}}{6MgO} + \underset{\text{carbon dioxide}}{36CO_2} + \underset{\text{water}}{15H_2O}$$

The insoluble oxide is then dissolved in diluted hydrochloric acid to convert it into magnesium chloride, according to the following equation:

$$\underset{\text{magnesium oxide}}{MgO} + \underset{\text{hydrochloric acid}}{2HCl} = \underset{\text{magnesium chloride}}{MgCl_2} + \underset{\text{water}}{H_2O}$$

The magnesium is precipitated from this solution by means of sodium phosphate T.S. and ammonia T.S., in the form of magnesium-ammonium phosphate, as explained under the assay of magnesium sulphate, page 1480. The ignition of this precipitate to magnesium pyrophosphate is also explained under magnesium sulphate (see above).

The Gravimetric Estimation of Manganese.

These assays require the precipitation of an insoluble compound of manganese and its subsequent ignition to manganous-manganic oxide.

Soluble Manganese Citrate—The manganese in this salt is first oxidized from the divalent to the tetravalent condition by means of peroxide of hydrogen in the presence of ammonia water which immediately precipitates manganic hydroxide. This precipitate is then filtered, washed, dried and ignited to constant weight, yielding a residue of manganous-manganic oxide (Mn_3O_4).

Soluble Manganese Glycerophosphate—The manganese is precipitated chiefly as sulphide in the presence of ammonia water and the mixture is boiled. The precipitate is then filtered, washed, dried, and ignited in an open crucible until its weight becomes constant. During this ignition the manganese is oxidized to manganous-manganic oxide (Mn_3O_4).

GASOMETRIC METHODS OF ANALYSIS

This type of assay method is based upon the evolution of a gas of definite composition. After adjusting the volume of the evolved gas to normal conditions of temperature and pressure, the corrected volume is converted into weight. The weight of the evolved gas is then calculated to a corresponding weight of the substance being determined. The following official substances are assayed by this general method:

Amyl Nitrite—The reagents that bring about the evolution of gas from amyl nitrite are potassium iodide and sulphuric acid, alcohol serving as the mutual

solvent. The gas evolved is nitric oxide (NO) and this gas is measured by means of an apparatus called a nitrometer, a full description of which is given on page 1517. The reaction involved is expressed as follows:

$$\underset{\text{amyl nitrite}}{2C_5H_{11}NO_2} + \underset{\substack{\text{potassium}\\\text{iodide}}}{2KI} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{2H_2SO_4} = \underset{\text{amyl alcohol}}{2C_5H_{11}OH} + \underset{\substack{\text{potassium}\\\text{bisulphate}}}{2KHSO_4} + \underset{\text{iodine}}{I_2} + \underset{\substack{\text{nitric}\\\text{oxide}}}{2NO}$$

Factors for the correction of the temperature and the barometric pressure are given in the U. S. P. text, page 1518.

Spirit of Ethyl Nitrite—This preparation is first agitated with potassium bicarbonate to neutralize free acid. An alcoholic solution of the product is then made to react with potassium iodide and sulphuric acid in a nitrometer (see page 920). Nitric oxide (NO) is evolved, according to the following equation:

$$\underset{\text{ethyl nitrite}}{2C_2H_5NO_2} + \underset{\substack{\text{potassium}\\\text{iodide}}}{2KI} + \underset{\substack{\text{sulphuric}\\\text{acid}}}{2H_2SO_4} = \underset{\text{ethyl alcohol}}{2C_2H_5OH} + \underset{\substack{\text{potassium}\\\text{bisulphate}}}{2KHSO_4} + \underset{\text{iodine}}{I_2} + \underset{\text{nitric oxide}}{2NO}$$

The factors for correcting the temperature and the barometric pressure are given in the U. S. P. text, page 1518.

SPECIAL ASSAY METHODS

Determining the Ability of a Soluble Sulphide to Precipitate Heavy Metals.

Sulphurated Potassa—The value of sulphurated potassa is estimated by having it precipitate copper sulphide from a solution containing a given weight of copper sulphate. One Gm. of the sulphurated potassa is required to precipitate 1 Gm. of copper sulphate from aqueous solution, subsequently testing for copper in the filtrate. Although the sulphurated potassa is a complex sulphide, the principle of the reaction may be illustrated by the following equation:

$$\underset{\substack{\text{copper}\\\text{sulphate}}}{CuSO_4} + \underset{\substack{\text{potassium}\\\text{sulphide}}}{K_2S} = \underset{\substack{\text{copper}\\\text{sulphide}}}{CuS} + \underset{\substack{\text{potassium}\\\text{sulphate}}}{K_2SO_4}$$

The Absorption of a Gas in a Solvent.

Oxygen—This assay depends upon the solubility of oxygen gas in an alkaline solution of pyrogallol. A measured volume of the gas is agitated with the alkaline solution of pyrogallol, in a calibrated tube, whereby, due to the absorption of the oxygen, a shrinkage in the volume of the gas is observed and noted.

Determination of Optical Rotation by Means of the Polariscope.

Spirit of Camphor—After taking the mean of several readings of the optical rotation of the spirit, the solvent is completely removed by evaporation. The residue of camphor is then sublimed and a weighed portion is dissolved in alcohol, to make a solution of standard strength. The mean of several polariscope readings from this solution is then taken as before. The two readings should be identical. If different, the amount of camphor in the original spirit can be calculated by following the directions given in the text of the U. S. P. assay, page 309.

The Estimation of Aldehydes and Ketones in Volatile Oils.

Determinations that depend upon the removal of an aldehyde or a ketone by means of sodium bisulphite, subsequently noting the volume of residual liquid.

Oil of Caraway, Oil of Cinnamon, and Oil of Spearmint—The active principles sought in the assay of these oils are the ketone, *carvone*, in both oil of caraway and oil of spearmint and the aldehyde, *cinnaldehyde*, in oil of cinnamon.

Aldehydes and ketones have the general property of combining with the alkaline bisulphites to form condensation products which separate from the oil. The reaction may be illustrated as follows:

$$NaHSO_3 + C_{10}H_{14}O = C_{10}H_{14}\begin{matrix}ONa\\HSO_3\end{matrix}$$

sodium bisulphite — carvone — carvone-sodium bisulphite

The sodium sulphite undergoes hydrolysis in solution, yielding sodium bisulphite and sodium hydroxide, as follows:

$$Na_2SO_3 + H_2O = NaHSO_3 + NaOH$$

sodium sulphite — water — sodium bisulphite — sodium hydroxide

The liberated alkali is constantly neutralized by the addition of more sodium bisulphite in solution.

The shrinkage in volume of the immiscible oil corresponds to the volume of carvone, or of cinnaldehyde present in the original oil.

Estimation of Ascaridol.

Oil of Chenopodium—A measured volume of this oil is agitated with a solution of acetic acid in a cassia flask (see Fig. 533). This renders the ascaridol water-soluble. The proportion of ascaridol present in the oil can then be determined by noting the volume of immiscible oil that remains.

Determinations by Electrolysis.

Alternate methods for the estimation of copper, mercury, silver and zinc by electrolysis are provided in the U. S. P. X., and are fully explained in the section on "Electrolytic Determinations", page 1515.

FIG. 533

Cassia flask

The Estimation of Phenols in Volatile Oils.

One of the main chemical properties of a phenol is its power to react with caustic alkali to form a water-soluble substance known as a phenolate.

Oil of Clove—A carefully measured volume of oil of clove is agitated with standard potassium hydroxide solution, in a cassia flask (see Fig. 533), and the volume of immiscible oil remaining after the agitation is noted. This is explained by the fact that eugenol, the chief constituent of oil of clove, is a phenol. During the agitation the eugenol is separated from the oil in the form of a water-soluble compound. The oily, non-eugenol residue is measured and its volume is subtracted from the volume of the original oil. The difference in volume corresponds to the volume of eugenol which has undergone the change described, or the amount present in the oil of clove.

Oil of Pimenta and Oil of Thyme—The assay of these oils involves the estimation of the phenols, eugenol and thymol, respectively. Both of these are

determined by agitation with caustic alkali solution, according to the method described above for oil of clove. The alkali prescribed in the oil of thyme assay is sodium hydroxide.

The Estimation of Phenols in Compound Solution of Cresol.

Liquor Cresolis Compositus—This solution is made possible by the combination of the cresol with caustic alkali to form water-soluble cresolates. In the assay these cresolates are decomposed by sodium bicarbonate as follows:

$$\underset{\text{sodium cresolate}}{C_6H_4CH_3ONa} + \underset{\substack{\text{sodium}\\\text{bicarbonate}}}{NaHCO_3} = \underset{\text{cresol}}{C_6H_4CH_3OH} + \underset{\substack{\text{sodium}\\\text{carbonate}}}{Na_2CO_3}$$

The liberated cresol is then distilled with purified kerosene and is subsequently removed from the kerosene distillate by agitation with a measured volume of aqueous sodium hydroxide solution. This treatment changes the cresol back into a soluble cresolate, increasing the volume of aqueous liquid. It is this increase in volume that is recorded as being due to the cresol. The cresol is later separated from the aqueous solution by adding an excess of hydrochloric acid. After washing the separated cresol with saturated salt solution, and drying with potassium carbonate, it should then meet the requirements for cresol as indicated in the text.

The Determination of Invert Sugar by Means of Fehling's Solution.

Sucrose—Fehling's solution is not directly reduced by pure sucrose. The presence of invert sugar, which is composed of equal molecules of the reducing sugars, dextrose and levulose, does effect a reduction of the copper salt with the formation of red cuprous oxide. The weight of dried cuprous oxide obtained should not exceed the figure given in the U. S. P. text and corresponds to not more than 0.5 per cent of invert sugar in the sucrose.

CHAPTER LXXXVIII

PROXIMATE ASSAYS

Proximate assays are applied particularly to the examination of vegetable drugs or other plants to determine the amount of medicinally active ingredients or other valuable constituents which may be present. The separations are dependent largely upon the use of various solvents, resulting from elaborate and painstaking research. Little use is made of the reagents customarily employed in chemical analyses, such as strong mineral acids and various salts; but chloroform, ether, alcohol, amyl alcohol, petroleum benzin, and other solvents assume an important rôle.

The term proximate assay is generally associated with the alkaloidal content of vegetable drugs and, while this is correct, there are many other important applications of the term.

The determination of the alcohol-soluble constituents in resinous drugs, as in asafetida, the volatile oil in aromatic drugs, as in clove, the fixed oil in various seeds, as in linseed, or in other oil-bearing portions of plants, and even the estimation of the sugar content of the sugar cane or of the sugar beet are examples of proximate assays. By proximate assay, therefore, is meant the determination of the amount of any organic constituent which may be present in any vegetable drug or plant.

Alkaloidal assays present, however, the most important application of proximate assay methods with which the pharmacist has to deal.

ALKALOIDAL ASSAYS

Work of a quantitative nature must necessarily be done with great care and in conducting proximate assays of alkaloidal drugs particular attention must be paid to all details.

The alkaloidal substances to be separated are organic chemical compounds, which are difficult to extract from the drug. They are present in comparatively small quantities and in many cases are easily destroyed by improper manipulation.

These assays are conducted largely through the use of immiscible solvents, such as chloroform, ether, amyl alcohol, etc., except where the properties of the alkaloid sought necessitates a special method, as for morphine in opium. Advantage is taken of the fact that the free alkaloids are practically insoluble in water (except colchicine and a few others), whereas they are very soluble in one or more of the immiscible solvents, such as chloroform, ether, etc. The salts of the alkaloids behave in the reverse manner, being practically insoluble in the immiscible solvents and soluble in water. There are several exceptions, such as the salts of caffeine, theobromine, colchicine, etc., which are feebly basic and dissociate easily with the liberation of the free alkaloid.

Three general steps are required for the separation and estimation of alkaloids:

1. Extraction of the alkaloid from the drug.
2. Purification of the alkaloid.
3. Estimation of the amount of alkaloid obtained, either by weighing or titrating.

Extraction of the Crude Drug.

The drug is reduced to the proper fineness by grinding (see page 157), and then subjected to any special treatment which may be directed, as in the caffeine assay in coffee when the fat is first removed by petroleum benzin. The powdered drug is then ready for extraction, the method depending upon the alkaloid present. Special methods for certain alkaloids are necessary.

The extraction methods may be divided into three classes:

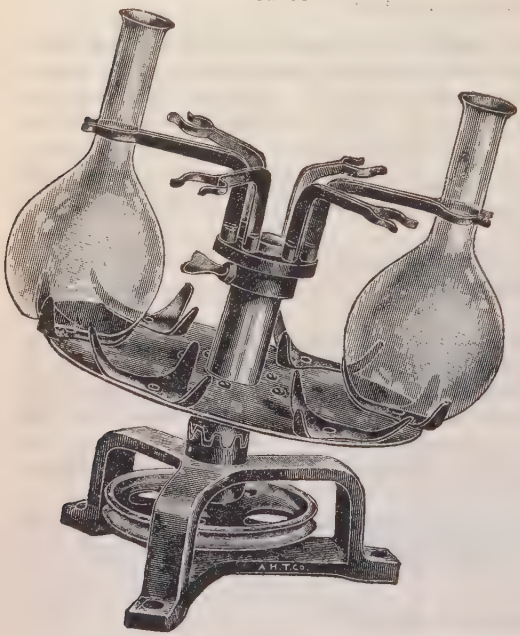
1. Extraction with water. (Estimation of morphine in opium, and colchicine in colchicum corm and seed.)

2. Extraction with an acid-aqueous solution. (Not required by any official assay.)

3. Extraction with chloroform, ether, or with a mixture of the two, or with purified petroleum benzin, an alkali, usually ammonia water, being added to liberate the alkaloids. (Belladonna, nux vomica, conium, etc.)

The extraction process under class 3 is used extensively in the U. S. P. X and N. F. V and is further subdivided into two methods of procedure as follows:

Fig. 534



Mechanical shaker

Type Process A—Aliquot Part Method—A definite weight of drug is macerated and agitated with a specific volume of solvent. A definite fractional portion of the saturated solvent is then taken for the continuation of the assay. This represents a correspondingly smaller quantity of the drug than was originally taken.

Type Process B—Total Extraction Method—A definite weight of the drug is percolated with the immiscible solvent until the alkaloid is completely extracted.

The extraction of crude drugs by type process A necessitates frequent shaking and when more than an occasional sample is to be examined the employment of a mechanical shaker will save much time, and will also insure more complete extraction of the drug (see Figs. 534 and 535).

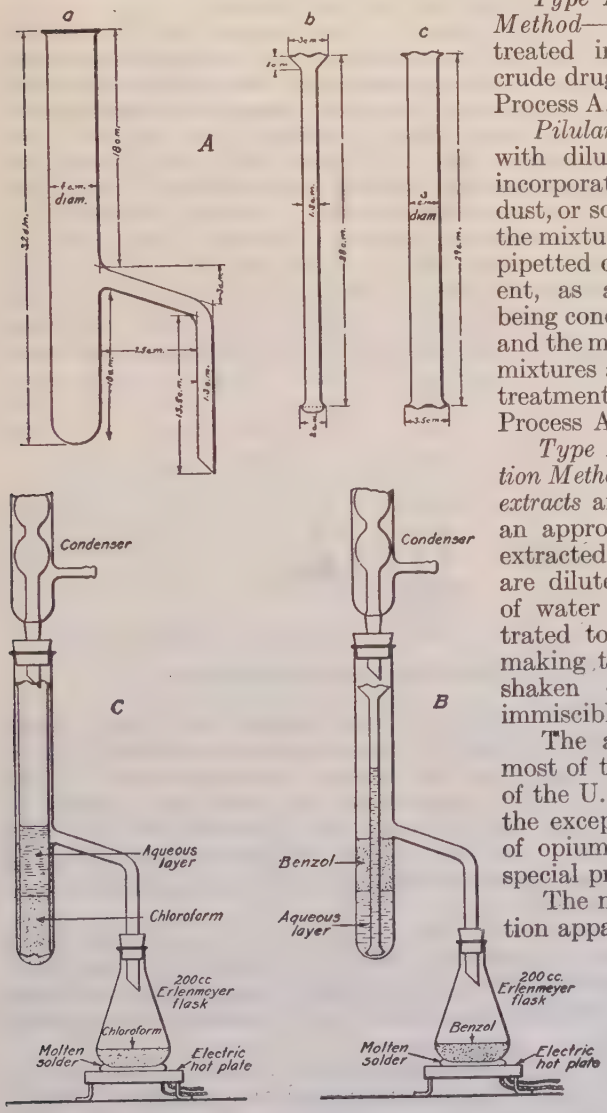
Fig. 535

Mechanical shaker

Extraction of Galenicals.

The assay processes for extracts, fluidextracts, tinctures, and powdered extracts of an alkaloidal drug are similar to those described for the crude drug, the details being as follows;

FIG. 536



Automatic extraction apparatus for alkaloids

Type Process C—Aliquot Part Method—Powdered extracts are treated in the same manner as crude drugs, explained under Type Process A.

Pilular extracts are liquefied with dilute alcohol, the solution incorporated with sufficient sawdust, or some other absorbent, and the mixture dried. *Fluidextracts* are pipetted directly upon the absorbent, as are also *tinctures* after being concentrated by evaporation and the mixture dried. These dried mixtures are then subjected to the treatment described under Type Process A for crude drugs.

Type Process D—Total Extraction Method—Powdered and *pilular extracts* are liquefied by the use of an appropriate solvent and then extracted directly. *Fluidextracts* are diluted with an equal volume of water and *tinctures* are concentrated to a small volume. After making the mixture alkaline it is shaken out, directly, with the immiscible solvent.

The above methods apply to most of the galenical preparations of the U. S. P. X and N. F. V with the exception of the preparations of opium and colchicum for which special procedures are required.

The need for automatic extraction apparatus for use in the assay of alkaloidal galenicals prompted the designing of an improved apparatus by chemists of the Drug Control Laboratory of the Bureau of Chemistry[1], Department of Agriculture. The simple type is easily constructed, requires only a small amount of solvent and practically no attention, and gives a clear extraction in one operation.

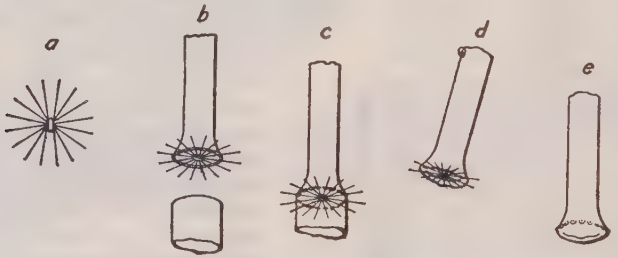
Automatic Extraction Apparatus—In the simple type of apparatus (Fig. 536)

[1] Automatic Devices for Extracting Alkaloidal Solutions by S. Palkin, A. G. Murray, and H. R. Watkins. Ind. and Eng. Chem., 1925, page 612.

the same jacket, condenser, and boiling flask are used for light and heavy solvents. For light solvents the funnel tube (*b*), containing very small openings at its lower end, is used in the jacket, as shown in *B*. For heavy solvents, as shown in *C*, the wide tube (*c*) open at both ends is used. The manner in which the extractors function is shown by the illustrations.

The construction of the funnel tube (*b*) is shown in Fig. 537. For the purpose of forming in the lower end of this tube a large number of very small openings, which break the solvent into a spray of minute droplets a "spider" (*a*) made of nichrome wire of the proper diameter is attached to the expanded end of the funnel tube (*b*). Another piece of tubing is then sealed to this expanded end, so as to leave the wires of the spider projecting through the walls of the tube (*c*). The tube below the spider is now sealed off as close to the wires as practicable (*d*). Upon dissolving the wire in nitro-hydrochloric acid, uniform openings of the size desired are formed (*e*). Soft glass is not as suitable for this purpose as hard glass, as the soft glass tends to flow over the wire, thus making subsequent solution in acid difficult. Pyrex is a suitable glass for this part of the apparatus. On account of the small diameter of the wire used (0.31 mm.), the spider cannot be made of copper because that metal would not

FIG. 537



Construction of funnel tube for automatic extraction apparatus

withstand the heat necessary to soften the glass. Although nichrome is resistant to the action of individual acids, there is no particular difficulty in dissolving it in boiling aqua regia. The spider is readily made as follows: Eight pieces of the nichrome wire, about 2.5 cm. long, are made into a bundle by binding the wires at the center with a short piece of stout copper wire, bent over and pressed tight with pliers. The sixteen branches are then spread out so as to extend radially from the copper band as a center and spaced equally apart, as shown in (*a*) (Fig. 537).

The completed funnel tube may be tested by forcing water through it under slight pressure, as the head is insufficient for water, although quite adequate for a hot solvent. These two extremely simple types of apparatus are sufficient for the great majority of extractions required in the pharmaceutical proximate assay.

For use with substances more difficult to extract, modified apparatus is suggested, in which the solvent enters the aqueous solution wholly or partly in the form of vapor, thus producing vigorous agitation and more rapid extraction than is obtained by the simple forms (see the original article).

Preparation of Solution—To obtain a clean alkaloidal residue by one extraction, the fluidextract or tincture is de-alcoholized and partially purified as follows: 25 cc. of the fluidextract (for tinctures use 100 cc.) and 3 cc. of normal sulphuric acid are evaporated on a steam bath to about 10 cc. and the resulting concentrate is diluted to 50 cc. and filtered.

Extraction—The apparatus shown in *B*, Fig. 536, is used. A 20 cc. portion of the filtrate (representing 10 cc. of the original sample) is pipetted into the extractor, which has been fitted to a 200 cc. Erlenmeyer flask. Two cc. of 8 per cent ammonium hydroxide solution and about 25 cc. of benzene are then added and the whole is slightly shaken to prevent the settling of any solid matter on the bottom of the extractor. The narrow funnel tube (*A*, *b*) (with the fine holes at the bottom) is introduced, and benzene is added until about 50 cc. overflows into the flask. The extractor is then arranged as shown in *B*. When the apparatus is in full operation there should be brisk boiling.

NOTE—Care should be taken not to permit the boiling to go on so rapidly as to cause the emulsion to be carried over into the flask. If this cannot be prevented, the extraction is allowed to proceed to completion, when the extracted aqueous liquid is discarded and the contents of the flask returned to the extractor, the flask washed with about 20 cc. of water and some fresh benzene, again transferred to the extractor, and the extraction repeated.

A fine spray of benzene should rise through the aqueous layer. The extraction is carried on for one or two hours. When complete, the benzene overlying the aqueous layer is separated and added to the main concentrate in the flask, which is connected to a clean, dry extractor (*A*), and the bulk of the solvent is recovered. The remainder of the solvent in the flask is then evaporated on a steam bath, the residue of alkaloids is taken up in a little absolute alcohol, and the evaporation is repeated to remove all traces of ammonia. The amount of alkaloid is determined in the usual way by titration.

Ipecac preparations are treated in a similar manner, but the solvent is ether, since the Pharmacopœial standard is based on the ether-soluble alkaloids. A 20 cc. portion of the fluidextract, with 5 cc. of normal sulphuric acid in a 100 cc. volumetric flask, is evaporated to a small volume, diluted, etc., and a 20 cc. aliquot portion of the filtrate (representing 4 cc. of the original fluidextract) is taken for the extraction.

Purification of the Alkaloid.

With the exception of the method using the automatic extraction apparatus, and in cases of tablets containing the pure alkaloids or their salts, the initial extraction is unsuitable for evaporating for final determination. The immiscible solvents remove other constituents such as oils, tannins, and soluble coloring, and these would interfere with the end-point in a titration or would add to the weight in a gravimetric assay. The purification of the alkaloid is therefore necessary. The methods used for this purpose vary according to the physical properties of the alkaloid sought.

1. *Crystallization*—While practically all alkaloids manufactured on a commercial scale are purified by crystallization, there is only one official assay which utilizes this method.

The value of opium and its products is based upon the morphine content and in this assay the morphine is separated by crystallization from many other alkaloids present. (See Opium assay, page 1498.)

2. *By Precipitation of Interfering Substances*—In the assay of colchicum corm and seed, a special method for removing interfering substances is necessary, since colchicine is feebly basic and does not form stable salts and also because it is very soluble in water. Coloring matter and other interfering substances are therefore removed by precipitation, by the addition of an excess of lead acetate.

3. *By Immiscible Solvents*—This method finds a greater use than any other in the U. S. P. and N. F. The alkaloid which has been removed in its free state from the crude drug or galenical by the use of some organic solvent is further purified by washing the organic solvent in a separatory funnel (Fig. 344) with

dilute acid. This converts the free alkaloid into the corresponding salt of the acid employed, when it is soluble in an aqueous solution only. For the final estimation it is necessary to have the free alkaloid and this is obtained by adding an excess of some alkali, usually ammonia water, to the acid washings. The alkaloid thus liberated by the addition of the alkali is then removed from the resulting alkaline mixture, by the use of an additional quantity of the immiscible solvent.

The operations involved in the transposition of the free alkaloid to the alkaloidal salt and then again to the free alkaloid, remove nearly all of the substances which might interfere with its final quantitative estimation.

4. *By Distillation*—A few of the alkaloids are volatile and may be separated or purified by steam distillation. The most important of this group are nicotine and coniine. Conium which is official in the National Formulary is assayed by the immiscible solvent method. Tobacco, which is not official, is assayed commercially for nicotine by the steam distillation method.[1]

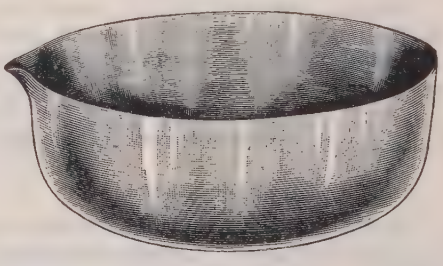
Estimation of the Alkaloid.

All of the U. S. P. X and N. F. V methods of separation and purification leave the alkaloid in the free state and in solution (except the opium assay

Fig. 538

Glass dish

Fig. 539



Platinum dish

where the morphine is crystallized) in some organic solvent as chloroform, ether, or petroleum benzin.

There are two methods official for estimating the amount of alkaloid or alkaloids, namely, the volumetric or titration method and the gravimetric or direct weighing method. The volumetric method is used wherever possible. It is necessary, however, to resort to gravimetric methods in some instances. Caffeine, hydrastine, and a few other alkaloids are only feebly basic and therefore do not lend themselves to titration. The total alkaloids of cinchona are also estimated gravimetrically.

By whichever method the estimation is carried out the alkaloid or mixture of alkaloids must first be separated from the organic solvent. The most economical procedure involves the recovering of the organic solvent for use in a subsequent assay. To do this the alkaloidal solution is very carefully distilled on a water bath until approximately 25 cc. of the solvent remains in the flask.

1. *Direct Gravimetric Method*—All of the official gravimetric methods require the direct weighing of the separated alkaloid or alkaloids. Either the entire final alkaloidal solution, or the alkaloidal solution in the distillation flask, is placed in a tared, glass dish (Fig. 538), or beaker, or preferably in a vessel of platinum (see Fig. 539). The original containers are rinsed with

[1] See the Official Methods of Analysis Association of Official Agricultural Chemist.

small quantities of the same solvent. Final evaporation to dryness is then carried out on a water bath and the residue treated at least twice with small portions of ether or alcohol and evaporated to dryness each time. This removes traces of chloroform. The residue in the dish is finally dried to constant weight at 100° C. (caffeine at 80° C.), the increase in weight being due to the alkaloid or alkaloids in the dish.

2. *Indirect Gravimetric Method*—With many organic and inorganic chemicals, the alkaloids and their salts form compounds which are insoluble in water. Advantage is often taken of this fact in identifying alkaloids and also occasionally in estimating them. The amount of quinine and cinchonidine in cinchona is estimated by the British Pharmacopœia by weighing the insoluble tartrates. Nicotine in tobacco and its extracts is estimated by precipitating the alkaloid with silico-tungstic acid, separating, purifying, and igniting this compound and calculating to nicotine by the use of a factor.

3. *Volumetric Method*—Volumetric alkaloidal assays are based upon the same principles as the volumetric assays of the inorganic chemicals (see page 1449). The alkaloids are capable of forming additive salts with acids, *i.e.*,

$$\underset{\text{morphine}}{2C_{17}H_{19}O_3N} + \underset{\substack{\text{sulphuric}\\ \text{acid}}}{H_2SO_4} = \underset{\text{morphine sulphate}}{(C_{17}H_{19}O_3N)_2.H_2SO}$$

It is this property of which advantage is taken in the volumetric assays.

The treatment of the final extraction is the same as has been explained under the gravimetric method, although a tared dish need not be used. If a porcelain evaporating dish is used for the evaporation, it will aid in the titration by providing a white background against which to observe the color change of the indicator.

To insure a complete reaction between the volumetric acid which is to be used and the partly purified alkaloid, it is usually the custom to add a few cc. of neutral alcohol to bring the alkaloid into solution before adding the acid. Ether or chloroform may also be used in this manner, then the volumetric acid and the distilled water added, and the solvent expelled by gently heating while stirring.

An excess of the standard acid (volumetric solution) is always added in the U. S. P. methods. This insures complete reaction with the alkaloid and leaves an excess of acid which must then be determined so that the amount which has been combined may be calculated. This is accomplished by titrating the excess of acid with fiftieth-normal sodium hydroxide, using an indicator to determine the end-point. Cochineal or methyl red are suitable indicators; the latter, however, is more stable and gives a sharper end-point. The fiftieth-normal sodium hydroxide should be prepared and stored as directed in the U. S. P. and should show no turbidity upon the addition to a small portion of a few drops of a saturated solution of barium hydroxide (*carbonate*). The alkali solution to be used should be standardized against the standard acid solution which is being used, using the same indicator and the same volume of water. When titrating the excess of alkali, in estimating the alkaloid in a proximate assay, the end-point of the reaction should be decided at the same degree of color as was used in standardizing the alkali.

The calculation required for determining the amount of alkaloid found is illustrated by the following typical titration:

Titration of empirical $\frac{N}{50}$ *NaOH*—

Measure exactly 10 cc. of a standard $\frac{N}{10}$ H_2SO_4, add methyl red and titrate: it requires 40 cc. of an empirical $\frac{N}{50}$ NaOH.

The 10 cc. of $\frac{N}{10}$ acid $\times$ 5 = 50 cc. of a strictly standard $\frac{N}{50}$ acid and in this example it corresponds to 40 cc. of the empirical $\frac{N}{50}$ alkali solution.

The alkali is therefore stronger than normality and the factor is $\frac{50}{40}$ of the normal strength, that is, every cc. of alkali solution used is equal to 1.25 cc. of standard $\frac{N}{50}$ alkali.

Alkaloidal Titration in an Assay of Nux Vomica—

To the alkaloids from 5 Gm. of nux vomica add 5 cc. of neutral alcohol to bring them into solution, then add 10 cc. of the $\frac{N}{10}$ acid. Warm gently to complete the reaction between the acid and the alkaloids. Now add a few drops of methyl red indicator, 25 cc. of distilled water, and titrate with the empirical $\frac{N}{50}$ alkali. There is now required 24 cc. of the empirical $\frac{N}{50}$ alkali to neutralize the excess of $\frac{N}{10}$ acid. The 24 cc. of empirical $\frac{N}{50}$ NaOH $\times$ 1.25 = 30 cc. of a strictly standard $\frac{N}{50}$ NaOH. Then 30 cc. of standard $\frac{N}{50}$ NaOH $\div$ 5 = 6 cc. of $\frac{N}{10}$ NaOH and 6 cc. $\frac{N}{10}$ NaOH is the equivalent of the uncombined $\frac{N}{10}$ H_2SO_4. As 10 cc. of $\frac{N}{10}$ H_2SO_4 was originally taken, by subtracting the 6 cc. of $\frac{N}{10}$ NaOH it is found that 4 cc. of $\frac{N}{10}$ H_2SO_4 was consumed by the alkaloids.

Each cc. of $\frac{N}{10}$ H_2SO_4 represents 0.03642 Gm. of nux vomica alkaloids. Multiply this by 4 cc. of the consumed $\frac{N}{10}$ H_2SO_4: it shows 0.14568 Gm. of alkaloids from the nux vomica.

Now 10 Gm. of nux vomica was originally extracted with 100 cc. of ether-chloroform and half of this used. Therefore the 0.14568 Gm. (or 145.68 mg.) of alkaloids has been obtained from 5 Gm. of nux vomica. The per cent strength of the nux vomica is then 0.1456 Gm. $\times$ 20 = 2.912 Gm. in 100 Gm. or 2.912 per cent.

If reference is made to the molecular weight of strychnine, it will be found to be 334.3. This is not the weight (364.2) that is used for calculating the alkaloidal content of nux vomica. The weight 364.2 is obtained by a calculation based on the average amount of strychnine (334.3) and brucine (466.4) normally present in nux vomica. This utilization of the molecular weight of the combined alkaloids, which is different from that of the chief alkaloid, will be found in a number of instances.

FACTORS OF IMPORTANCE IN PROXIMATE ASSAYS

1. The drug must be of proper fineness.
2. The agitation must be for a definite time.
3. The extraction must be for the required period.
4. The extraction with immiscible solvents must be complete. Test with mercuric potassium iodide T.S. or iodine T.S.
5. There must be a sharp separation of immiscible solvents.
6. Carefully avoid loss of material by spurting, on account of pressure created in the separatory funnel.
7. Avoid emulsions; these can often be broken up by rotating a rubber tipped stirring rod against the walls of the separatory funnel, by gently warming, by adding more solvent, or by the addition of a few cc. of alcohol, delivered into the organic solvent.
8. To ensure freedom of the final organic extraction from ammonium salts, filter through paper wetted with the solvent. If the alkaloid is pure it may spatter when final portions of the solvent are evaporated. The addition of a few cc. of alcohol will generally prevent this.

9. Do not subject the alkaloids of hyoscyamus to a high temperature. In examining hyoscyamus remove the dish from the source of heat just before the last few cc. of solvent are evaporated, and continue the evaporation spontaneously.
10. In gravimetric assays avoid drying at too high a temperature.
11. In volumetric assays be sure that all of the alkaloid is brought into solution so that it may react with the standard acid.

The Official General Directions for Alkaloidal Assays are as Follows:

Fineness of Powders

The portion to be assayed, which must represent the entire drug, is to be in powder of specified fineness. This is interpreted to mean that the drug powder must not be coarser than the size specified, but finer powders may be used.

Extraction of the Alkaloids

Extraction with Immiscible Solvents—For the extraction of alkaloids from an ethereal or chloroformic solution, use dilute acid. The strength of the acid and the quantity employed are left to the discretion of the operator, but it is advisable to use the smallest quantity which can be conveniently handled. Shaking should not be violent, but should be sufficient to mix the liquids thoroughly without forming an emulsion. The extraction with acid must be repeated until the alkaloid is completely removed from the ethereal or chloroformic liquids. Each portion of acid solution as drawn off should be filtered through cotton or filter paper. If preferred, the combined acid solutions may be washed with a little chloroform or ether, this in turn washed with distilled water, and the water added to the acid solution.

In shaking out an alkaline aqueous solution with an immiscible solvent, the process must be repeated until the extraction of the alkaloid is complete. Each portion of solvent as drawn off should be filtered through cotton or filter paper.

Care must be taken to avoid loss of alkaloidal solutions through imperfect separation, creeping, or other similar conditions.

Ether-Chloroform Mixture—When a mixture of ether and chloroform is employed, the proportion of the mixture is to be three volumes of ether and one volume of chloroform, cooled to working temperature after being mixed.

Evaporation of Solvents—The evaporation of the final alkaloidal solution may be conducted by distillation, by evaporation on a water bath, or by means of a current of warm air. In evaporating chloroform solutions, the residue should be treated with ether or alcohol, which is in turn evaporated to carry off the last traces of chloroform.

As the alkaloids from hyoscyamus are very sensitive to heat, a solution of these alkaloids should not be evaporated to dryness on a water bath. After the last trace of chloroform has evaporated spontaneously, 1 or 2 cc. of neutral alcohol should be added and warmed but not entirely evaporated, then cooled and titrated immediately.

Titration of the Alkaloid—When the alkaloid is to be estimated by titration, the residue is dissolved in neutralized alcohol, the volumetric acid, accurately measured, is added, and followed by a convenient quantity of distilled water. The excess of acid is immediately determined by titration with fiftieth-normal sodium hydroxide. If preferred, the residue is dissolved in ether or chloroform, the volumetric acid and distilled water added, and the ether or chloroform expelled by gentle heat before titrating.

Indicators—The indicators to be employed in the titration of alkaloids are cochineal T.S. and methyl red T.S. These are interchangeable and either may be used at the discretion of the operator.

Gravimetric Determination—When the alkaloid is to be estimated gravimetrically, the solvent is evaporated, as above directed, in a tared flask or beaker. The residue is dried to constant weight at 100° C. and weighed.

Type Processes for Alkaloidal Assays

Type Process A for Drugs—Aliquot Part Method

Extraction of the Drug—Place the accurately weighed drug in a dry flask or bottle of suitable capacity, add the required volume of solvent, accurately measured, stopper securely with a well-fitting cork stopper and shake. Allow to stand for at least five minutes, add 10 cc. of ammonia T.S., stopper tightly, and shake for one hour in a mechanical shaker, or intermittently during two hours. In the case of intermittent shaking, agitation must be vigorous for at least one minute and be repeated at intervals of not more than fifteen minutes. Allow the mixture to stand overnight, again shake intermittently during one-half hour, and then allow the drug to settle. If the supernatant liquid is not clear, add a few cc. of distilled water, shake vigorously, and again allow to settle.

Decant an aliquot part of the liquid, accurately measured at approximately the same temperature at which the original solvent was measured. Transfer the liquid to a separator, rinsing the measuring container with a small quantity of the solvent and adding the rinsing to the separator.

Shaking out with Acid—Completely extract the alkaloid from the ethereal or chloroformic solution by shaking with successive portions of dilute sulphuric acid, and filtering each portion drawn off or washing with ether or chloroform if preferred. After extracting with several portions of acid, test a few drops of the last portion used for the presence of alkaloid. Extraction must be continued until not more than a very faint cloudiness results upon the addition of a drop of mercuric potassium iodide T.S. or, in the case of hydrastis or colchicum, upon the addition of a drop of iodine T.S.

Shaking out with Immiscible Solvent—Add a portion of the specified solvent to the combined acid solutions and make the mixture alkaline with ammonia T.S. Completely extract the alkaloid from the aqueous liquid with successive portions of the solvent, filtering each portion as drawn off. After extracting with several portions of the solvent, evaporate about 1 cc. of the last portion used, dissolve the residue in a few drops of dilute acid, and test for the presence of alkaloid. Extraction must be continued until not more than a very faint cloudiness results upon the addition of a drop of mercuric potassium iodide T.S. or, in the case of hydrastis or colchicum, upon the addition of a drop of iodine T.S.

Determination of Alkaloidal Content—Determine the alkaloid volumetrically or gravimetrically as directed.

Type Process B for Drugs—Total Extraction Method

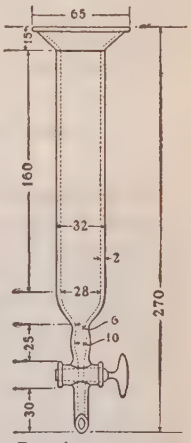
Extraction of the Drug—Place an accurately weighed quantity of the ground drug in a small cylindrical percolator (see Fig. 540), previously prepared by packing the outlet with cotton. Add a sufficient amount of the solvent to saturate the drug completely and mix thoroughly. Cover the percolator and allow it to stand at least five minutes, then add 5 cc. of ammonia T.S., and mix this thoroughly with the drug. After macerating for one hour, pack the

drug firmly, place a pledget of cotton above it and percolate slowly with the solvent until the drug is completely extracted. The percolation must be continued until upon evaporating 3 or 4 cc. of the percolate, dissolving the residue in a few drops of dilute acid, and adding a drop of mercuric potassium iodide T.S., only a very faint cloudiness results.

Any suitable percolator may be used, but one similar in form and size to that illustrated is recommended.

From this point proceed as directed under *Type Process A*, beginning with the words "Transfer the liquid to a separator", page 1494.

FIG. 540



Percolator recommended for Type Process B (measurements are given in millimeters).

TYPE PROCESS C FOR GALENICAL PREPARATIONS—ALIQUOT PART METHOD

Preparation of the Sample—*Powdered Extracts*—When powdered extracts are assayed by the aliquot part method, they are to be treated as directed, under the powdered drug. If the extract has a tendency to form lumps in the solvent, mix it with an equal bulk of clean sand or powdered pumice. If lumps form after the addition of the ammonia, they should be disintegrated by the addition of a little water.

Pilular Extracts—Liquefy an amount of extract, accurately weighed, approximating the quantity directed, by warming with sufficient diluted alcohol, or with the menstruum used in making the extract, stirring with a glass rod. To the thoroughly liquefied extract, contained in a small evaporating dish, add sufficient sawdust or other suitable material (see below) to absorb the liquid, and dry at a temperature not exceeding 60° C. Transfer the dry mixture to a flask or bottle containing the specified quantity of solvent, and remove any traces of material adhering to the dish by rinsing with successive small portions of ammonia T.S., using a total of 10 cc. and adding the ammoniacal rinsings to the solvent. Continue as directed under Type Process A, beginning with the words "stopper tightly and shake for one hour", page 1494, fourth line.

Fluidextracts—Pipette the fluidextracts directly upon the sawdust, or other suitable material (see below), contained in a small evaporating dish, dry at a temperature not exceeding 60° C. and transfer as directed under *Pilular Extracts* to a flask or bottle containing the specified quantity of solvent. Proceed as directed under Type Process A, beginning with the words "stopper tightly and shake for one hour", page 1494, fourth line.

Tinctures—Concentrate the specified quantity of tincture by evaporation at a temperature not exceeding 60° C. to a volume of about 10 to 15 cc., add sufficient sawdust or other suitable material (see below) to absorb the liquid, and continue the heat until dry. Transfer the dry mixture, as directed under *Pilular Extracts*, to a flask or bottle containing the specified quantity of solvent. Then proceed as directed under Type Process A, beginning with the words "stopper tightly and shake for one hour", page 1494, fourth line.

Absorbents—The absorbent employed may be sawdust, gauze, cheesecloth, paper pulp, asbestos fiber, absorbent cotton, or any similar suitable substance. Sawdust should be clean, not resinous, and must not show the presence of alkaloids when tested as follows: Macerate 5 Gm. in 50 cc. of ether-chloroform mixture and 10 cc. of ammonia T.S., shaking frequently during two hours. Decant 10 cc. of the clear ethereal liquid, evaporate to dryness, and treat the

residue with 1 cc. of diluted sulphuric acid. Test portions of the acid liquid for alkaloids with mercuric potassium iodide T.S. and with iodine T.S.

If necessary, sawdust may be purified for use in assays by extracting it in a percolator, first with a 1 per cent solution of sodium hydroxide, then with a 1 per cent solution of hydrochloric acid, finally washing with distilled water until free from acid and soluble salts, and drying. The last portions of the acid percolate must give no test for alkaloid with mercuric potassium iodide T.S. or with iodine T.S.

Type Process D for Galenical Preparations—Total Extraction Method

Preparation of the Sample—*Powdered and Pilular Extracts*—Liquefy an amount of extract, accurately weighed, approximating the quantity directed, by digesting in about 10 cc. of diluted alcohol, or in the menstruum used in making the extract. Transfer the liquid to a separator containing a portion of the specified solvent, and rinse all traces of the extract from the dish, using small portions of diluted alcohol, or menstruum, and adding the rinsings to the separator. Dilute the alcoholic liquid with an equal quantity of distilled water, add sufficient ammonia T.S. to make it decidedly alkaline, and completely extract the alkaloids by shaking with successive portions of the solvent. Complete the assay as directed under Type Process A, beginning with the words "Shaking out with acid".

Fluidextracts—Pipette the fluidextracts directly into a separator containing a portion of the specified solvent, add a volume of distilled water about equal to that of the fluidextract taken, render the liquid alkaline by the addition of ammonia T.S., and completely extract the alkaloids by shaking out with successive portions of the solvent. Complete the assay as directed under Type Process A, beginning with the words "Shaking out with Acid", page 1494.

Tinctures—Concentrate the specified quantity of tincture by evaporation at a temperature not exceeding 60° C. to a volume of about 10 to 20 cc. Transfer the concentrated liquid to a separator containing a portion of the specified solvent, and rinse all traces of the liquid from the dish, using small portions of diluted alcohol, and adding the rinsings to the separator. Add a volume of distilled water equal to that of the alcoholic liquid, render the liquid alkaline by the addition of ammonia T.S., and completely extract the alkaloids by shaking out with successive portions of the solvent. Complete the assay as directed under Type Process A, beginning with the words "Shaking out with acid".

Explanations of the Proximate Assays of the U. S. P. X and N. F. V

Belladonna Leaves—Type Process B.

The ground drug, which must be at least in a fine (No. 60) powder, is extracted by type process B (see page 1494), the total extraction method. The addition of ammonia liberates the alkaloids and they are then removed by percolation with ether-chloroform mixture (see page 1493). The percolate should be concentrated by evaporation or distillation if more than 100 cc. It is then placed in a separatory funnel and shaken out with dilute acid (25, 20, 20 and 20 cc. portions of 0.5 per cent sulphuric acid). The shaking should be rotatory and not violent, to avoid emulsification. Each acid extraction is passed into a separatory funnel through filter paper placed in a funnel. A few cc. of the last extraction should be drawn off into a test tube and a drop of

mercuric potassium iodide T.S. added. No turbidity should appear, indicating that the "shaking out" has been complete. If turbidity appears, additional acid extractions should be made. The acid extractions are now rendered alkaline by the addition of ammonia water to again liberate the alkaloids. They are now extracted with several portions of chloroform (25, 20 and 20 cc.). The addition of the chloroform should be made cautiously, as the mixture may be quite warm and this might cause boiling and subsequent loss. Each chloroformic extraction is filtered as drawn off and a few cc. of the last extraction are evaporated, taken up in dilute acid, and tested with mercuric potassium iodide T.S. If turbidity results, more chloroform extractions are made until complete extraction is obtained. The extractions are now evaporated on a water bath and the alkaloids obtained and titrated as already described. The amount of alkaloid found, expressed in grams and multiplied by 10, will indicate the per cent present in the drug.

Belladonna Plaster—The plaster mass, consisting of the adhesives and the extract of belladonna, is removed from the backing by washing with chloroform. The rubber is then precipitated by adding alcohol. A small quantity of ammonia T.S. is now used to convert the alkaloidal salts of the extract into free bases, the rubber is separated, and the general process is then followed (see Belladonna Leaves, page 1496).

Belladonna Root—Type Process B. (See Belladonna Leaves, page 1496.)

Cinchona—Type Process A. Add the acid and water to the ground cinchona as directed on page 1113, and apply heat. This is done to make the subsequent liberation of the alkaloids easier by breaking up their combination with tannin. The flask in which this operation has been conducted is now cooled, the ether-chloroform mixture added, and then 10 cc. of ammonia water to liberate the alkaloids. The subsequent "shake outs" are carried on in the same manner as under Belladonna Leaves. All of the final chloroform extractions are evaporated in a weighed dish and dried at 100° C. The increased weight, expressed in grams, and multiplied by 25, will give the per cent of alkaloids in the drug.

Colchicum Corm—(See Colchicum Seed).

Colchicum Seed—The alkaloid colchicine, found in the seed or corm, is very soluble in water and therefore does not lend itself to the usual shaking out methods. The drugs are extracted with warm water to which is added lead acetate to precipitate the resins, soluble coloring matter, etc. The extraction is now filtered and the excess lead removed with sodium phosphate and the mixture again filtered. The colchicine is now extracted from the aqueous solution with chloroform and the chloroformic extractions are evaporated. A small portion of alcohol is added, it is again evaporated to dryness, and this is repeated. The addition of the alcohol breaks down any compound which the alkaloid may have formed with the chloroform. After drying at 100° C., the weight of the dish with the residue is determined, then a quantity of $\frac{N}{10}$ H_2SO_4 and distilled water are added to bring the alkaloid into solution. The solution is now filtered through a pledget of absorbent cotton to remove the impurities, the alkaloidal solution is discarded, and the cotton washed with water. The insoluble matter on the cotton is then washed with alcohol, then with ether and the washings evaporated in the dish formerly used and dried at 100° C. The dish and the impurities are again weighed and this total weight subtracted from the first total weight obtained is the weight of the colchicine in the aliquot portion of drug taken.

Extract of Belladonna—Type Process D. The extract is brought into solution by using diluted alcohol and is then extracted with chloroform after

having been made alkaline. This solution is treated exactly as directed for the percolate under the Assay of Belladonna Leaves, page 1496.

Extract of Colchicum—(See Colchicum Seed, page 1497.)

Extract of Hyoscyamus—Type Process D. (See Extract of Belladonna, page 1497.)

Extract of Nux Vomica—Type Process D. (See Extract of Belladonna, page 1497.)

Extract of Stramonium—Type Process D. (See Extract of Belladonna, page 1497.)

Fluidextract of Belladonna Leaves—Type Process D. To a definite portion of the fluidextract add an equal quantity of water and make the solution alkaline. Extract this with chloroform and treat the chloroformic extractions as directed for the chloroform percolate under Belladonna Leaves, page 1496.

Fluidextract of Belladonna Root—Type Process D. (See Fluidextract of Belladonna Leaves, above.)

Fluidextract of Cinchona—Type Process C. Pipette a portion of the fluidextract onto an absorbent substance such as sawdust, sand, or asbestos (see Absorbents, page 1495), and dry this at a temperature below 60° C. Now treat the dried material in the same manner as the crude drug, omitting the initial acid treatment.

Fluidextract of Colchicum—The fluidextract is diluted with water and then treated as directed under Colchicum Seed, page 1497.

Fluidextract of Hydrastis—Type Process D. The diluted fluidextract is treated as directed under Hydrastis, below.

Fluidextract of Hyoscyamus—Type Process D. (See Fluidextract of Belladonna Leaves, above.)

Fluidextract of Ipecac—Type Process D. (See Ipecac, below.)

Hydrastis—Type Process A. The usual method must be modified so that all of the extractions are made with ether. This eliminates the berberine but removes the hydrastine and other alkaloids. The extracted alkaloids are weighed.

Hyoscyamus—Type Process B. The percolation method is employed for the extraction of the drug, using a mixture of chloroform and ether, with chloroform alone for the final extraction. Great care should be taken in evaporating the final extraction, as the alkaloids of hyoscyamus are easily destroyed by heat. The dish should be removed from the source of heat before all of the chloroform is evaporated and the final chloroform removed by spontaneous evaporation. A small amount of alcohol is then added and the dish *warmed* slightly. Then add the acid and titrate.

Ipecac—Type Process A. In this assay use ether only as the original extracting agent and also as the final organic solvent.

Nux Vomica—Use Type Process A, page 1494.

Opium—The assay of opium is the most elaborate of the assays. This is because the morphine content alone is to be determined, which necessitates the removal of a number of other alkaloids. The alkaloid morphine is present largely as the meconate. In the official process the opium is extracted with water to remove the morphine, codeine, thebaine, and certain other alkaloids, which are present as soluble salts. The narcotine, which is present in quantities of from 1 to 9 per cent, is retained largely in the insoluble residue. The aqueous extract is now concentrated and freshly slaked lime is added. This produces a solution of calcium hydroxide in which morphine, a phenolic body, is soluble. The mixture of lime and opium extract is now filtered, and this eliminates a large amount of the codeine which is only sparingly soluble in the calcium hydroxide solution. The filtrate now contains the

morphine, thebaine, a trace of codeine, and some of the unimportant alkaloids, and the morphine is obtained from this solution by crystallization. Morphine is soluble in solutions of the fixed alkalies but is practically insoluble in very dilute ammonia solutions. Also it is sparingly soluble in ether.

Ether is now added to the aqueous solution and the solution is saturated with it by shaking. A small amount of ammonium chloride is then added, from which ammonia is liberated by the fixed alkali, calcium hydroxide. The mixture is vigorously shaken over a definite period, which removes the traces of codeine and other alkaloids, these being soluble in ether. The morphine which has thus been freed through the addition of the ammonia, gradually crystallizes.

Complete crystallization of the morphine requires several hours and is preferably carried on in a cool place. The morphine appears in abundant crystals which are sometimes large but at other times small, for no apparent reason. These crystals are separated from the mother liquor by first passing the ether through a pledget of absorbent cotton in a funnel, adding more ether to wash, and then transferring the supernatant aqueous liquids also to the funnel. The crystals in the flask are drained and then a few drops of distilled water, which has been previously saturated with morphine, are added. This is poured through the cotton and the operation repeated until the washings are colorless. This washing removes the free ammonia and interfering coloring matter without dissolving the morphine. The morphinated water is now displaced by using a few drops of distilled water. Separation and purification of the morphine is now complete and the crystals are ready to be titrated according to the usual procedure.

Opium Granulated—(See Opium, page 1498).

Opium Powdered—(See Opium, page 1498).

Stramonium—Type Process B. (See Belladonna Leaves, page 1496.)

Tincture of Belladonna—Type Process D. (See Fluidextract of Belladonna Leaves, page 1498.)

Tincture of Cinchona—Type Process C. (See Cinchona, page 1497.)

Tincture of Cinchona, Compound—Type Process C. (See Cinchona, page 1497.)

Tincture of Colchicum—A 150 cc. portion of the tincture is evaporated to small bulk and then diluted with water. The resins and coloring matter are removed with lead acetate and the procedure is then followed as already explained under Colchicum Seed, page 1497.

Tincture of Hyoscyamus—Type Process D. (See Fluidextract of Belladonna Leaves, page 1498.)

Tincture of Nux Vomica—Type Process D. (See Fluidextract of Belladonna Leaves, page 1498.)

Tincture of Opium—An 80 cc. portion of the tincture is evaporated to remove the alcohol. The solution is now treated as under opium, page 1498.

Tincture of Stramonium—Type Process D. (See Fluidextract of Belladonna Leaves, page 1498.)

Assays of the N. F. V.

Extract of Conium—The extract is mixed with a small amount of water and dilute hydrochloric acid. This acid, aqueous mixture retains the coniine while the fat and coloring matter is removed by repeated agitation with small portions of petroleum benzin. These benzin washings are discarded. The alkaloid is now liberated by adding potassium carbonate (ammonium hydroxide cannot

be used). Then petroleum benzin is again used to extract the alkaline mixture, the coniine now being removed. Several extractions are made until all alkaloid is extracted.

The combined petroleum benzin washings of the alkaline mixture are filtered through paper into a flask to remove extraneous matter, and to the filtrate is added 10 cc. of tenth-normal sulphuric acid. The benzin is now evaporated at a gentle heat, stirring frequently, the presence of the acid being necessary to fix the alkaloid since free coniine is volatile.

The excess of acid is titrated in the usual manner and from this the amount of alkaloid present is calculated.

Extract of Hydrastis—Type Process C. The extract is treated as directed for the drug hydrastis, under Type Process A (see Hydrastis, page 1498).

Extract of Ignatia—Type process C. The extract is treated as directed for the drug ignatia (see Ignatia, page 1501).

Fluidextract of Colchicum Corm—The fluidextract is diluted with water and then treated as directed for the aqueous extraction of the drug (see Colchicum Seed, page 1497).

Fluidextract of Guarana—As the alkaloid of guarana is caffeine which does not form stable salts, this necessitates a modification of the usual method of assay. The fluidextract is made alkaline and all of the alkaloid removed by repeated extraction with chloroform. The chloroform extracts are evaporated to dryness at a temperature below 80° C. to avoid loss of caffeine. A quantity of hot water is added to dissolve the alkaloid, and the solution allowed to cool. It is now filtered to remove traces of any non-alkaloidal substance extracted by the chloroform and the filtrate and washings are then completely extracted with chloroform and the chloroformic extracts evaporated in a tared dish. The dish and crude alkaloid in the dish are dried at 80° C. and weighed, and the increase in weight is estimated as caffeine from the amount of fluidextract taken.

Fluidextract of Kola—(Proceed as directed under Fluidextract of Guarana, page 1501).

Fluidextract of Nux Vomica—Type Process D. (Proceed as directed under Fluidextract of Belladonna Leaves, page 1498.)

Tincture of Colchicum Corm, Stronger—The directed quantity of tincture is evaporated to remove the alcohol and then diluted with water. This solution is now treated as directed for the aqueous extract of the drug (see Colchicum Seed, page 1497).

Tincture of Hydrastis—Type Process D. The evaporated tincture is extracted directly with ether (see Hydrastis, page 1498).

Tincture of Ignatia—Type Process D. The evaporated tincture is extracted directly with chloroform (see Fluidextract of Belladonna Leaves, page 1498).

Tincture of Ipecac—Type Process D. The evaporated tincture is extracted with ether only.

Tincture of Opium with Saffron—An 80 cc. portion of the tincture is evaporated to remove the alcohol and then assayed as under Opium, page 1498.

Coffee, Roasted—Caffeine which is the alkaloid present does not form stable salts and this necessitates a special method. A chloroformic extraction of the coffee is made in the presence of ammonia. A portion of this extract which contains the caffeine, and other undesired extractive substances, is evaporated to dryness at a low temperature. The residue is dissolved in about 10 cc. of warm, 1 per cent sulphuric acid, and allowed to cool. This solution is filtered to remove traces of fat and other material and the dish and filter washed with small portions of water. The filtrate and washings are then made

alkaline with ammonia water, then completely extracted with chloroform, and the combined chloroformic extracts evaporated to dryness in a tared dish at 80° C. The increase in weight of the dish is assumed to be due to the caffeine obtained from the coffee.

Conium—The active principle sought in the assay is coniine, a liquid, volatile alkaloid. The extraction of the drug follows the general procedure of type process A (page 1494) except that petroleum benzin is used as the solvent. To liberate the alkaloid it is necessary to use a fixed alkali instead of ammonia water. Evaporation of the final benzin extractions is made in the presence of the tenth-normal acid, as explained under Extract of Conium (page 1499).

Guarana—Caffeine is the alkaloidal constituent of the drug guarana and the assay is that already explained under Roasted Coffee (page 1500).

Ignatia—Type Process A. The aliquot part of the ether-chloroform extract of the drug is treated in the same manner as the chloroform percolate of belladonna leaves (see page 1496).

Kola—(See Guarana, above).

Assaying Alkaloidal Tablets

Among the many important medicinal articles handled by the pharmacist are tablets containing potent alkaloids. These tablets in many cases, especially hypodermic tablets, are relied upon by the physician in emergency to produce quick results. The necessity for the tablets complying with their stated alkaloidal content can be readily seen.

Degree of Accuracy—The following proposed tolerances and methods of analysis for tablets of this character were recommended by the contact committees of the American Drug Manufacturers' Association and the American Pharmaceutical Manufacturers' Association[1] on December 9, 1925, to the Bureau of Chemistry of the United States Department of Agriculture.

Proposed Tolerances in Hypodermic Tablets

Apomorphine hydrochloride	7.5 per cent
Arecoline hydrobromide	7.5 per cent
Caffeine	7.5 per cent
Caffeine and sodium benzoate—to contain of anhydrous caffeine not less than 43.5 per cent nor more than 53.7 per cent of the labeled amount of caffeine and sodium benzoate.	
Cocaine hydrochloride	9.0 per cent
Codeine phosphate—to contain of anhydrous codeine alkaloid not less than 61 per cent nor more than 75 per cent of the labeled content of codeine phosphate.	
Codeine sulphate	9.0 per cent
Morphine and atropine (morphine content)	9.0 per cent
Morphine sulphate	7.5 per cent
Physostigmine salicylate	10.0 per cent
Physostigmine sulphate	10.0 per cent
Pilocarpine hydrochloride	7.5 per cent
Procaine	7.5 per cent
Strychnine sulphate, purporting to contain 1/40 grain or more	7.5 per cent
Strychnine sulphate, purporting to contain less than 1/40 grain	9.0 per cent
Strychnine nitrate, purporting to contain 1/40 grain or more	7.5 per cent
Strychnine nitrate, purporting to contain less than 1/40 grain	9.0 per cent

Methods of Analysis—A sufficient number of tablets should be dissolved to represent 1 grain of the medicament, unless otherwise directed. In no case should less than twenty (20) tablets be used and if these contain more than 1 grain of medicament, an aliquot of the solution, representing 1 grain, should be taken for analysis.

The aqueous solution may now be extracted by hand shaking, using a separatory funnel or by the use of the automatic extraction apparatus (see page 1487).

Apomorphine Hydrochloride Hypodermic Tablets—Dissolve not less than 20 tablets in enough distilled water to make 100 cc. and take an aliquot, equivalent to at least 1 grain of apomorphine hydrochloride. To the aqueous solution add 0.5 Gm. of sodium bicarbonate and shake out with several portions of ether, until the aqueous layer is shown to be completely exhausted of alkaloid, using Mayer's reagent for the

[1] These recommendations are of April, 1926; later reports may be obtained from the Bureau of Chemistry, United States Department of Agriculture, Washington, D. C.

test. Combine the ether extracts in a separatory funnel, and wash three times with 5 cc. portions of distilled water, separating the water carefully and completely after each shaking, and collecting it in a second separatory funnel. Shake out the united water washings once with a small portion of ether. Separate completely and add the ether washings to the combined ether extracts. To the ethereal solution add a measured excess (10 cc.) of N/20 sulphuric acid. Shake the mixture thoroughly and draw off the aqueous layer into a small flask or beaker. Wash the ethereal solution twice more with small portions of distilled water and add to the acid liquid. Finally titrate the excess of acid with N/50 potassium hydroxide, using methyl red as the indicator. Each cc. of N/20 sulphuric acid corresponds to 0.015636 Gm. of apomorphine hydrochloride [$C_{17}H_{17}O_2N$ HCl.$\frac{1}{2}H_2O$].

Arecoline Hydrobromide Hypodermic Tablets—Dissolve not less than 20 tablets in enough distilled water to make 100 cc. and take an aliquot, equivalent to at least 4 grains of arecoline hydrobromide. Add an excess of N/10 silver nitrate, 3 cc. of 10 per cent nitric acid, and 3 cc. of ferric ammonium sulphate T.S. Allow to stand about five minutes, and titrate the excess of silver nitrate with N/10 potassium thiocyanate until a faint brown color persists after shaking. Each cc. of N/10 silver nitrate corresponds to 0.02359 Gm. of arecoline hydrobromide.

Caffeine Hypodermic Tablets—Follow the directions under *Caffeine and Sodium Benzoate Hypodermic Tablets*, multiplying the weight of caffeine obtained by 1.093 to obtain the weight of the caffeine [$C_8H_{10}O_2N_4.H_2O$] in the sample taken.

Caffeine and Sodium Benzoate Hypodermic Tablets—Dissolve not less than 20 tablets in a minimum amount of distilled water in a separatory funnel. Add 3.5 cc. of sodium hydroxide T.S. and shake the mixture with four successive portions of 20 cc., 10 cc., 10 cc., and 5 cc. of chloroform. Pass the chloroform solutions through a filter which has been previously moistened with chloroform, and wash the stem of the funnel and filter with a few cc. of hot chloroform to remove any adhering caffeine. Evaporate the combined chloroform solutions on a water bath and dry the residue, consisting of anhydrous caffeine [$C_8H_{10}O_2N_4$] to constant weight at 80° C.

Cocaine Hydrochloride Hypodermic Tablets—Dissolve not less than 20 tablets in sufficient distilled water to make 100 cc. and take an aliquot, equivalent to at least 1 grain of cocaine hydrochloride. Make the aqueous solution slightly alkaline with ammonia T.S. and shake out with several portions of ether until the aqueous layer is shown to be completely exhausted of alkaloid, using Mayer's reagent for test. Combine the ether extracts and evaporate one-half of the ether on a water bath.

Return the solution to a separatory funnel and wash out three times with 5 cc. portions of distilled water, separating the water carefully and completely after each shaking, and collecting it in a second separatory funnel. Shake out the water washings once with a small portion of ether. Separate completely and add the ether washing to the combined ether extracts. To the ethereal solution add a measured excess (10 cc.) of N/20 sulphuric acid, shake the mixture thoroughly and draw off the aqueous layer into a small flask or beaker. Wash the ethereal solution twice more with small portions of distilled water and add to the acid solution. Finally, titrate the excess of acid with N/50 sodium hydroxide, using methyl red as the indicator. Each cc. of N/20 sulphuric acid corresponds to 0.016983 Gm. of cocaine hydrochloride [$C_{17}H_{21}O_4N$HCl].

Codeine Phosphate Hypodermic Tablets—Follow the directions under *Codeine Sulphate Hypodermic Tablets* except that the ammonia T.S. is replaced by sodium hydroxide T.S. and the chloroform extraction is to be washed with a small quantity of distilled water. Each cc. of N/20 sulphuric acid corresponds to 0.014964 Gm. of anhydrous codeine alkaloid [$C_{18}H_{21}O_3N$].

Codeine Sulphate Hypodermic Tablets—Dissolve not less than 20 tablets in sufficient distilled water to make 100 cc. and take an aliquot, equivalent to at least 1 grain of codeine sulphate. Make the aqueous solution alkaline with ammonia T.S. and shake out with several portions of chloroform, until the aqueous solution is shown to be exhausted of alkaloid, using Mayer's reagent for the test. Evaporate the combined chloroform extracts to dryness on the water bath, and dissolve the residue in a few cc. of neutral alcohol. Add 10 cc. of N/20 sulphuric acid and titrate the excess of acid with N/50 potassium hydroxide, using methyl red as the indicator. Each cc. of N/20 sulphuric acid corresponds to 0.019663 Gm. of codeine sulphate [$(C_{18}H_{21}O_3N)_2H_2SO_4.5H_2O$].

Morphine Sulphate Hypodermic Tablets—Dissolve not less than 20 tablets in sufficient distilled water to make 100 cc. and take an aliquot, equivalent to at least 1 grain of morphine sulphate. Render the aqueous solution slightly alkaline with ammonia T.S., and shake out six times with a mixture consisting of 3 parts of chloroform and 1 part of alcohol. Evaporate the combined extracts to dryness on a water bath and dissolve the residue in a few cc. of neutral alcohol. Add 10 cc. of N/20 sulphuric acid and titrate the excess of acid with N/50 potassium hydroxide. Each cc. of N/20 sulphuric acid corresponds to 0.018962 Gm. of morphine sulphate [$(C_{17}H_{19}O_3N)_2H_2SO_4.5H_2O$].

Optional Method—Follow the directions as given under *Morphine and Atropine Hypodermic Tablets*.

Morphine and Atropine Hypodermic Tablets (for morphine content)—Take a sufficient number of tablets to represent about 8 grains of morphine sulphate, place in a 100 cc. Erlenmeyer flask, and dissolve in 12 cc. of morphinated water. Add, drop by drop, ammonia T.S., until the odor of ammonia is apparent. Shake thoroughly, and let the flask stand in a cool place overnight. Collect the crystals of morphine alkaloid on a filter, wash the crystals with morphinated water and then with a little distilled water to replace the morphinated water. Place the filter paper and contents in an Erlenmeyer flask and add 20 cc. of N/10 sulphuric acid. Break up the filter paper with a glass rod, heat for about one hour, until the alkaloid is completely dissolved, and then titrate with N/50 potassium hydroxide, using methyl red as the indicator. Each cc. of N/10 sulphuric acid corresponds to 0.037932 Gm. of morphine sulphate U. S. P. [$(C_{17}H_{19}O_3N)_2H_2SO_4.5H_2O$].

Physostigmine Sulphate or Physostigmine Salicylate Hypodermic Tablets—Follow the directions under *ApomorphineHydrochloride Hypodermic Tablets* except to evaporate ether extractions first on a water bath and finally spontaneously. Each cc. of N/20 sulphuric acid corresponds to 0.016215 Gm. of physostigmine sulphate [$(C_{15}H_{21}O_2N_3)_2H_2SO_4$] or 0.02066 Gm. of physostigmine salicylate [$C_{15}H_{21}O_2N_3C_7H_6O_3$].

Pilocarpine Hydrochloride Hypodermic Tablets—Follow the directions under *Codeine Sulphate Hypodermic Tablets*. Each cc. of N/20 sulphuric acid corresponds to 0.012234 Gm. of *pilocarpine hydrochloride* [$C_{11}H_{16}O_2N_2HCl$].

Procaine Hydrochloride Hypodermic Tablets—Follow the directions under *Codeine Sulphate Hypodermic Tablets* except to evaporate the extractions at room temperature in a tared dish. The weight of the residue multiplied by 1.1545 corresponds to the weight of the procaine hydrochloride [$C_{13}H_{20}O_2N_2HCl$] in the sample taken.

Strychnine Sulphate or Strychnine Nitrate Hypodermic Tablets—Follow the directions given under *Codeine Sulphate Hypodermic Tablets*. Each cc. of N/20 sulphuric acid corresponds to 0.021414 Gm. of strychnine sulphate [$(C_{21}H_{22}O_2N_2)_2H_2SO_4.5H_2O$], or to 0.01986 Gm. of strychnine nitrate [$C_{21}H_{22}O_2N_2HNO_3$].

CHAPTER LXXXIX

BIOLOGIC ASSAYS

THE number of drugs and their preparations to which it is necessary to apply *Biologic Assay* methods is not large. Most chemical substances such as the various bromides, chlorides, sulphates, etc., being definite chemical compounds of *known composition*, can be satisfactorily assayed by chemical methods. Chemical methods may also be used for such drugs as opium, belladonna, nux vomica, etc., in which the active constituents can be isolated in the *pure form* by chemical processes.

There are, however, a number of drugs and their preparations which *cannot* be satisfactorily assayed by chemical methods, either for the reason that their active principles are *not known* or that they *cannot be quantitatively isolated in the pure state* by any of the known chemical methods. In this list are found such important drugs in common use as *digitalis, strophanthus, squill, convallaria, apocynum, aconite, solution of epinephrine hydrochloride, solution of pituitary, ergot, cannabis, gelsemium, and veratrum.* Since there are no satisfactory chemical methods of assay for this list of drugs, recourse must be had to standardization by *biologic methods.*

The necessity for applying biologic assay methods to this class of drugs and their preparations is apparent when we consider that Edmunds and Hale[1], Roth[2], and Pittenger[3] have shown that *unstandardized preparations of these drugs vary in strength from 0 to 444 per cent.*

It is not only essential to know that a drug contains valuable medicinal properties, but in order to secure the best therapeutic results these must be present in the commercial preparations in definite and constant amounts. With the above list of drugs this assurance can be obtained only by means of *biologic standardization.*

The U. S. P. IX included the following statement in reference to *Biologic Assays:*

"Inasmuch as there are several drugs more or less extensively used in the treatment of disease for which no satisfactory chemical method of assay has been developed, other assays have been introduced in which these drugs are administered to animals and the effects noted. From the results obtained from these assays the strength of the preparation is calculated, and, if necessary, proper corrections are made so that the preparation shall conform to the standard which has been adopted. The official drugs to which these methods of assay have been applied in the following pages, are the members of the digitalis group, cannabis, and aconite, and the suprarenal gland.

"Brief descriptions of the more commonly accepted methods are given here in order, first, to direct the attention of manufacturers to them; second, to ascertain the points of weakness which may exist in them; and, finally, to outline methods and establish standards which those interested may adopt should they desire to assay their products and have them conform to the standards proposed. All preparations thus assayed and made to conform to these standards may be labeled 'Physiologically Assayed and Standardized According to the U. S. P. IX.'

---

[1] Edmunds and Hale, U. S. Hygienic Lab. Bull. No. 48, p. 10.
[2] Roth, U. S. Hygienic Lab. Bull. No. 102, p. 5.
[3] Pittenger, "Biochemic Drug Assay Methods," p. 6.

"In the case of cannabis and its preparations, the biologic assay standards are compulsory."

During the period in which the U. S. P. IX was official, the various biologic assay methods were improved to a point where it was considered advisable, in the interest of uniformity, to make a greater number of methods compulsory.

The U. S. P. X, therefore, includes compulsory biologic assays for the following drugs and preparations: Aconitine, Aconite and its tincture, Cannabis and its fluidextract, Digitalis and its tincture, Ergot and its fluidextract, Squill and its fluidextract and tincture, Strophanthus and its tincture, Solution of Epinephrine Hydrochloride, and Solution of Pituitary.

The purpose of the biologic assay, just as of the chemical assay, is to secure a means of measuring therapeutic activity and to make it possible to furnish uniform preparations. A satisfactory method which meets these requirements may or may not involve the production of physiologic reactions similar to those produced by the drug when used therapeutically. That the physiologic action chosen as a means of standardization does not parallel the clinical effect sought is not sufficient to condemn the method. It is only necessary that the effect chosen as an earmark is always indicative of a good quality of the drug or preparation, and criticisms of methods on the ground that they are *toxic* methods or that the animal chosen is biologically much different from man are made only through a lack of conception of the real purpose of the biologic test, namely, to secure *uniformity*. The determination of the real value of a drug in the treatment of disease in man is another matter entirely.

The various official biologic assay methods may be divided into the following three general types:

Type 1. *Toxic Methods* in which guinea pigs or frogs are used, the value of the drug or preparation depending upon the amount required to produce the death of the animal. Examples: The "one hour frog" method for assaying digitalis, strophanthus, and squill and the "guinea pig" method for assaying aconite.

Type 2. Assays depending upon *the amount of drug or preparation required to produce some specific effect upon the intact animal.* Examples: The assay of cannabis on dogs, the "cock's comb test" for ergot, and the assay of solution of epinephrine hydrochloride for its effect on the blood pressure of dogs.

Type 3. Assays depending upon *the amount of drug or preparation required to produce some definite effect upon an isolated organ.* Example: The action of solution of pituitary on the isolated uterus of the virgin guinea pig.

Type 1—Bio-Assay Methods

The official drugs and preparations which are assayed by Type 1 methods and the biologic assay processes adopted by the Pharmacopœia, are as follows:

DIGITALIS

Digitalis, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each gram of body weight of frog. It contains not more than 2 per cent of browned leaves, stems, flowers, or foreign organic matter, and yields not more than 5 per cent of acid-insoluble ash.

Assay—Prepare a tincture according to the official process and proceed as directed under *Tinctura Digitalis.*

Tincture of Digitalis, injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.0055 cc. and not more than 0.0065 cc. equivalent to not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each Gm. of body weight of frog.

Assay—Use healthy frogs of the same species (*Rana pipiens* Schreber) and of a fairly uniform size (20 to 30 Gm.).

Storage—Before use, the frogs should be stored in constant temperature tanks, kept in a cool room, preferably where the temperature does not rise above 15° C. The bottom of the tanks should be covered

with running water. The day before the frogs are to be used, a sufficient number should be taken from the storage tanks and placed in a tank, the temperature of which is approximately 20° C. One hour before the assay, they are weighed to within 0.5 Gm. and placed in wire cages or containers in a tank containing water to the depth of about 1 cm. (½ inch), the water being kept at a uniform temperature of 20° C. during the assay.

Dose—The doses of the tincture to be given the frogs are calculated according to the weights of the frogs and are injected into the ventral lymph sac by means of a pipette or glass syringe which is graduated in hundredths of a cubic centimeter. The injection is made into the lymph sac through the floor of the mouth, care being taken not to puncture the skin. The amount of fluid to be injected into the different frogs should be as uniform in quantity as possible, approximately 0.015 cc. for each Gm. of body weight of frog. In case the alcohol content in any preparation after dilution is higher than 20 per cent, the preparation may be subjected to careful evaporation and subsequent addition of distilled water until the original volume is restored and the alcohol content is not above the per cent named. The animal is replaced in its cage in the tank after injection, the temperature being maintained at 20° C.

About fifty-eight minutes from the time of injection, each frog is pithed, the heart is exposed, and its condition examined. For the correct end-reaction, at the expiration of one hour from the time of injection, the ventricle must be in systolic standstill, while the auricles are widely dilated. Following mechanical stimulations, feeble contractions may occur in the auricles and localized contractions in the ventricle, but no general contraction is allowable.

If, when the lymph sac is opened to expose the heart, any of the injected drug is found unabsorbed, the animal must be discarded and not considered in the results obtained.

SQUILL

Squill, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each Gm. of body weight of frog.

Assay—Prepare a tincture according to the official process and proceed as directed under *Tinctura Digitalis.*

Fluidextract of Squill, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.00,055 cc. and not more than 0.00,065 cc. of fluidextract, or the equivalent in Fluidextract of not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each gram of body weight of frog.

Assay—Proceed as directed under *Scilla.*

Tincture of Squill, injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.0055 cc. and not more than 0.0065 cc., equivalent to not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each Gm. of body weight of frog.

Assay—Proceed as directed under *Tinctura Digitalis.*

STROPHANTHUS

Strophanthus, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.00,006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each gram of body weight of frog.

Assay—Prepare a tincture by the official process and proceed as directed under *Tinctura Digitalis.*

Tincture of Strophanthus, injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.00,005,5 cc. and not more than 0.00,006,5 cc., equivalent to not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each Gm. of body weight of frog.

Assay—Proceed as directed under *Tinctura Digitalis.*

It will be noted, therefore, that for the drugs of the *digitalis series* (digitalis, strophanthus, and squill), the so-called "one hour frog" method is employed. This method consists essentially in ascertaining the minimum dose of the drug or preparation which will bring the heart of a standard sized frog to systolic standstill in one hour.

In routine laboratory work four frogs are generally used for the first series of injections. These are injected as described above with 9/10, 10/10, 11/10 and 12/10 respectively, of the standard dose of the preparation being tested for each gram of body weight of frog. The animals are then placed in cages in the tank, arranged to maintain a temperature of 20° C., and allowed to remain there for fifty-eight minutes. They are then removed, pithed (both brain and cord), the heart is exposed, and its condition noted.

After the primary or trial assay has been carried out and the approximate strength of the preparation ascertained, a second series of frogs are injected in like manner, using doses, the limits of which are considerably narrower than the first series. A third or even fourth series of injections may be necessary to confirm the earlier results. The dose thus found is then compared with the dose of the standard, which is similarly ascertained upon another series of frogs of the same lot. From such a comparison the strength of the unknown preparation can be suitably adjusted.

The use of a standard is made necessary by the fact that frogs differ in their susceptibility to the members of the digitalis series at different seasons of the year. The condition of susceptibility is ascertained and allowed for by the use of a solution of *ouabain* as a standard which in appropriate doses is injected into a series of frogs and their resistance thus determined. The necessary strength of an unknown preparation may be calculated from the dose actually found by the ratio of the standard dose of ouabain to the dose of ouabain found necessary to kill. Thus:

Standard dose of ouabain : Found dose of ouabain :: Standard dose of drug being assayed : Necessary dose of unknown

The standard dose of ouabain is 0.00,000,05 Gm. per Gm. of body weight of frog.

The standard dose of tincture of digitalis to correspond is 0.006 cc. per Gm. of body weight of frog.

If, therefore, in a certain series of frogs the resistance to ouabain is found to be increased so that a dose of 0.00,000,075 Gm. is necessary to stop the heart in systole within one hour, the dose of the tincture of digitalis would also have to be increased to 0.009 cc. and the actual dose found calculated against this, instead of against the standard dose of 0.006 cc. For example: in frogs showing the increased resistance as indicated above, if the tincture being examined assays 0.018 cc. per Gm. of body weight of frog, it is one-half strength.

ACONITE, AND TINCTURE OF ACONITE

Aconite, in the form of the tincture, administered subcutaneously to guinea pigs, has a minimum lethal dose not exceeding 0.0004 cc. of tincture for each gram of body weight of guinea pig. Aconite contains not more than 5 per cent of its stems or 2 per cent of other foreign organic matter.

Assay—Prepare a tincture by the official process, and assay as directed under *Tinctura Aconiti.*

Tincture of Aconite, administered subcutaneously to guinea pigs, has a minimum lethal dose of not less than 0.00,035 cc. and not more than 0.00,045 cc. for each Gm. of body weight of guinea pig.

Assay—Use guinea pigs weighing from 275 Gm. to 325 Gm. each and in good health. Dilute the Tincture with distilled water to make the dose about 1 cc., and inject into the guinea pig under the skin of the abdomen. The standard dose must kill within six hours at least two of every three guinea pigs injected.

The method for the assay of aconite, therefore, consists in determining the *minimum* dose per Gm. of body weight of guinea pig that will prove fatal within six hours, when the drug is subcutaneously injected. This is usually termed the *minimum lethal dose* or "M. L. D."

The usual practice is to inject a series of four guinea pigs with 0.0002, 0.0003, 0.0004, and 0.0005 cc., respectively, of the tincture, per Gm. of body weight of guinea pig. The animals are then placed in cages and allowed to remain six hours; at the end of this time they are examined and a note made of those living and those dead.

The results of this preliminary test, in which the range of dosage is quite wide, enables the investigator to form some idea of the strength of the preparation. Basing the dosage upon these results, other series of guinea pigs are injected with progressively increasing or decreasing doses, as the case may be, still further diminishing the variation between doses, until the smallest amount is found which will prove fatal within six hours. The probable minimum lethal (toxic) dose of the preparation, unless it deviates considerably from that of the standard, is generally obtained by one or two series of injections. In order to determine whether or not this is the true minimum lethal dose, this result is checked by carefully injecting a new series of four pigs, two with the smallest dose that was found to kill, and two with the largest dose that did not kill. If, however, any of this last series show irregularities, further tests must be made.

After thus determining the M. L. D. of the unknown preparation, its percentage strength as compared with the standard is calculated by simple proportion as follows:

M. L. D. of unknown : Standard M. L. D. :: 100 : X

Type 2—Bio-Assay Methods

The official drugs and preparations which are assayed by Type 2 methods and the biologic assay processes and standards adopted by the Pharmacopœia are as follows:

CANNABIS

Cannabis, in the form of the fluidextract, administered by the mouth to dogs in doses not exceeding 0.1 cc. for each kilogram of body weight of dog, produces a degree of incoördination equivalent to that caused by the same dose of the standard fluidextract of cannabis, prepared as directed below. It contains not more than 10 per cent of its fruits, large foliage leaves, stems over 3 mm. in diameter, and not more than 2 per cent of other foreign organic matter. It yields not more than 5 per cent of acid-insoluble ash.

Assay—Use adult dogs which weigh less than 15 kilograms and which are susceptible to the action of Cannabis. The dogs must not be fed for twelve hours before being used and observations should be made within one hour after administration. The same animal must not be used for testing purposes at shorter intervals than three days. Administer the fluidextract in gelatin capsules by the mouth.

Standard Fluidextract of Cannabis

Prepare a composite fluidextract, representing at least ten different lots of Cannabis, conforming to the official botanical description, and administer this fluidextract in gelatin capsules to dogs by the mouth. This standard fluidextract must be so adjusted that it will produce incoördination in dogs which have been found to be susceptible to the action of Cannabis when administered in doses of 0.03 cc. for each kilogram of body weight of dog.

Extract of Cannabis, administered by the mouth to dogs, in doses not exceeding 0.004 Gm. for each kilogram of body weight of dog, produces a degree of incoördination equivalent to that caused by 0.03 cc., for each kilogram of body weight of dog, of the standard fluidextract of cannabis prepared as directed under *Cannabis.*

Assay—Administer the Extract in gelatin capsules, proceeding as directed under *Cannabis.*

Fluidextract of Cannabis, administered by the mouth to dogs in doses not exceeding 0.1 cc. for each kilogram of body weight of dog, produces the same degree of incoördination as that produced by an equivalent dose of the standard fluidextract of cannabis, prepared as directed under *Cannabis.*

Assay—Proceed as directed under *Cannabis.*

The assay of cannabis and its preparations is based upon the fact that this drug produces certain symptoms of muscular incoördination. Within one hour after receiving a dose of suitable size of cannabis the dog loses control of its legs and of the muscles supporting the head, so that, when standing, the feet are usually spread apart to maintain balance. When nothing occurs to attract attention the head droops and the body sways from side to side or anteroposteriorly. A distinct ataxia is present when walking, and, when severely affected, the animal will stagger and fall. If, however, it is spoken to sharply or attention is drawn to anything of interest it may momentarily recover and the typical effects of the drug disappear, but in a few minutes it again relapses into the former condition. As the action of the drug progresses, the muscular incoördination becomes greater and the animal passes into deep, undisturbed sleep. After several hours the effects of the drug slowly disappear and the normal condition returns.

The assay method consists of ascertaining the dose of the preparation to be tested which will produce these symptoms of incoördination in dogs and then adjusting its strength by comparison with a standard preparation.

Dogs—The animals differ considerably in susceptibility to the drug and therefore it is best to make preliminary tests with average-sized doses upon several dogs and select from among them the animals which react easily to the drug. As a rule, fox terriers serve very well for the purpose, but any dog may prove satisfactory. It is best to provide at least two dogs for each assay, but if many samples are to be examined, more dogs will be needed. The dogs should be at least one year old and in normal health and must be kept under

the best sanitary conditions. They may be used repeatedly for the purpose, but not at shorter intervals than three days. Each series of tests should be conducted by the same operator who should be perfectly familiar with the peculiarities of each animal that he may more certainly recognize deviations from the normal. While the tests are being made, the animals should be kept in a quiet room, free from disturbance, and separated so that they cannot see each other.

Preparation of the Drug—The drug may be given most conveniently in the form of the fluidextract which is administered in gelatin capsules. In order to hasten absorption, the animal should not be fed for twelve hours before administering the drug.

Method of Administration—The drug is administered internally by means of a small gelatin capsule. The animal's mouth is opened by forcing the thumb and index finger of the left hand between the jaws, back of the teeth. The capsule is then placed on the back of the tongue with the right hand and the mouth quickly closed; while still holding the mouth shut, the animal can be made to swallow the capsule immediately by slapping it on the throat.

Assay—An average dose of the known or standard preparation is given to one of the dogs and a like dose of the preparation to be standardized is given to the second dog. After one hour both dogs are observed very carefully for symptoms of muscular incoördination. The incoördination is manifested differently in different animals, but in small doses it shows itself most frequently in slight swaying, when the animal is standing quietly, or in some ataxia when it runs about.

The results obtained from the first test should be confirmed after an interval of not less than three days by repeating the administration but reversing the order, that is, giving the known strength drug to the dog which received that of unknown strength before and *vice versa*.

In subsequent tests, the dose of the preparation of unknown strength is modified so as to produce symptoms similar to those produced by the standard. If the preparation to be tested is below the standard in strength, its dose must be increased, or if it is above strength, its dose is lessened until equivalent doses of the two are found. Dogs may be used over long periods of time, even for some years, but occasionally they have to be discarded, as in some cases they seem to learn the effects of the drug and so refuse to stand up. A certain degree of tolerance is sometimes gained which necessitates larger doses.

ERGOT

Ergot produces stimulation of unstriped muscle, partly central, but mainly peripheral, the action being exerted in the ganglionic cells or preganglionic endings. This in turn produces contractions of the uterus, blood vessels, and intestines.

Endeavors to measure these various actions have resulted in the development of three methods of biologic standardization:

1. The blood pressure method.
2. The cock's comb method.
3. The uterine method—(a) in situ; (b) isolated.

The U. S. P. Revision Committee has adopted the *cock's comb method* as the official assay process.

This method consists in determining the minimum amount of fluidextract of ergot necessary to cause the same degree of bluing in the cock's comb and

wattles as that produced by a given amount of a standard preparation, when introduced into the crop or when intramuscularly injected.

The official standard and assay process are as follows:

Ergot, in the form of the fluidextract, administered by intramuscular injection to single-comb, white Leghorn cocks, in doses not exceeding 0.5 cc. for each kilogram of body weight of cock, produces a darkening of the comb, corresponding in intensity to that caused by the same dose of a standard fluidextract of ergot, prepared as directed below. It contains not more than five per cent of seeds, fruits or other foreign organic matter.

Assay—Use single-comb, white Leghorn cocks, which are less than eighteen months of age, and weigh approximately two kilograms. Injections are made deeply into the breast muscles, and the effects are observed within one hour to one hour and a half after the administration of the drug. The same cock must not be used for testing purposes at shorter intervals than two weeks.

Standard Fluidextract of Ergot

Prepare a composite fluidextract, representing at least ten different lots of Ergot, conforming to the official botanical description. This standard fluidextract, which must be aged for at least six months before being standardized by the method described in the preceding paragraph, and must be preserved in a vacuum, when administered by intramuscular injection in doses not exceeding 0.5 cc. per kilogram of body weight of cock, produces darkening of the comb of a single-comb, white Leghorn cock which is less than eighteen months of age, and which weighs approximately two kilograms.

Fluidextract of Ergot, administered by intramuscular injection to single-comb, white Leghorn cocks, in doses not exceeding 0.5 cc. for each kilogram of body weight of cock, produces a darkening of the comb, corresponding in intensity to that caused by the same dose of the standard fluidextract of ergot prepared as directed under *Ergota*.

Assay—Proceed as directed under *Ergota*.

The usual procedure is to inject one cock with a dose of the standard preparation and another with the same dose of the unknown preparation, and within one hour to one hour and a half after the injections have been given, compare the color of the two combs, as the maximum cyanosis seems to be reached in about that time. The color begins to fade soon after, so that at the end of two hours or more, depending on the amount of drug given, the comb will usually appear to be nearly normal. Judging from the results obtained from the first two injections, the dose of the unknown preparation is increased or diminished until that amount is found which will give approximately the same intensity of action as was shown by the color of the comb of the cock injected with the standard. The same cocks may be used for several tests, but the injections should be made at intervals of two weeks to allow sufficient time for complete recovery from the effects of previous administrations of the drug. It should not be considered sufficiently accurate if the first injections of the standard and of the unknown preparations produce the same degree of activity, because it is believed that individual variation in different birds might be sufficiently great to interfere. This variation can be reduced to a minimum, if the order of injection on the succeeding tests is reversed until each preparation has been given to each of several birds in turn. The results are then based on the average of the several injections. The final comparisons demand careful selection of the birds to be injected. A choice of two birds of about the same size and which had previously reacted well to the drug is advisable. With a little practice it is easy to compare the intensity of the discoloration in the two cocks' combs and to so regulate the dose of the drug given as to produce approximately the same degree of reaction. The doses thus obtained will give the relative strength of the two drugs.

Variations may further be avoided by using only such cocks as react alike to a standard preparation, and also by constantly changing the order of injections so that the same cock shall not receive the same specimen of the drug twice in succession.

SOLUTION OF EPINEPHRINE HYDROCHLORIDE

Epinephrine acts peripherally on a variety of structures probably by stimulating the sympathetic nerve endings. Its most important therapeutic action consists in a constriction of the blood vessels with consequent high rise

in blood pressure, a slowing of the heart, due to stimulation of the vagus center, and a direct stimulant and tonic effect on the heart muscle. Of these actions the effect upon the blood pressure presents the best means of biologic standardization.

The official assay, therefore, depends upon the characteristic, transitory, quantitative rise in blood pressure in dogs, produced by the intravenous injection of *submaximal doses* properly diluted.

The official standard and assay process are as follows:

Solution of Epinephrine Hydrochloride, diluted with physiological solution of sodium chloride in the proportion of one part of the Solution of Epinephrine Hydrochloride to 99 parts of the salt solution, and injected intravenously into dogs by the method described below, produces a rise in the systolic blood pressure of the dog corresponding to that produced by an equal amount of the standard solution of epinephrine hydrochloride prepared as directed below.

Assay—Prepare a standard solution of epinephrine hydrochloride from the standard epinephrine by dissolving 0.050 Gm. of epinephrine in 5 cc. of tenth-normal hydrochloric acid, and dilute this to 50 cc. by the addition of distilled water, thus making a 1 in 1000 solution. For the assay, add 1 cc. of this 1 in 1000 solution to 99 cc. of physiological solution of sodium chloride. This dilute solution (1 in 100,000) must be freshly prepared when needed. On account of the possibility of deterioration, the 1 in 1000 solution must have been recently prepared. It will keep for a short time if preserved in amber-colored bottles in a refrigerator, but it must be discarded if any signs of deterioration, such as discoloration, are observed.

Add 1 cc. of the Solution of Epinephrine Hydrochloride to be tested to 99 cc. of physiological solution of sodium chloride, and thoroughly mix.

For the purpose of the assay, the dog to be used should be of medium size and be anesthetized with a suitable anesthetic. It is prepared for blood pressure estimations by inserting a cannula into the carotid artery and connecting the same with a mercury manometer. The trachea may also be exposed and a cannula inserted so that the animal may receive artificial respiration during the course of the experiment if necessary. The injections are made into the exposed femoral vein. Before the test is made, in case any muscular movement such as twitching is present, the dog should receive by intravenous injection a sufficient dose of curare (page 1533), but if the animal is deeply anesthetized, this is not necessary. The dog should also receive a sufficient dose of atropine sulphate (from 0.001 Gm. to 0.002 Gm.) to paralyze the vagi, this paralysis being proved by electrical stimulation. The blood pressure tracing is recorded on a kymograph. Injections must be made at regular intervals of approximately five minutes. Determine the amount of standard solution necessary to cause a rise in blood pressure of from 30 to 60 mm. by injecting intravenously varying doses of the solution and after a satisfactory dose has been ascertained, the uniformity of reaction should be tested by the injection of two or more doses of equal size. If these injections produce approximately equal increases in blood pressure, alternate injections of the solution to be tested and of the standard are made, varying the amount of the unknown until two or more successive injections raise the blood pressure to the same height, indicating that the amount of active agent is the same in the doses used. From the results thus obtained, the strength of the unknown solution may be determined and adjusted.

Type 3—Bio-Assay Method

Solution of pituitary is the only official preparation assayed by the Type 3 method.

SOLUTION OF PITUITARY

Physiologic experiments and clinical experience have *demonstrated that solution of pituitary accelerates diuresis, raises the blood pressure by arterial constriction,* excites marked *uterine contractions* and has a rather marked *galactagogue action.*

Of these actions, three present themselves as possible means of biologic standardization, *i.e.*, the action on the blood pressure, the uterus, and the kidneys.

It has been shown by Dale and Laidlaw that methods of standardization based on the diuretic action are unsatisfactory because of the tolerance produced by the first injection.

The blood-pressure method, although strongly advocated by some workers, has been proved by most experimenters to be less accurate than the isolated uterus method.

It will be noted, therefore, that the official method is based upon the effect of a pituitary extract on the isolated uterus of the virgin guinea pig.

The value of the preparation depends upon the amount required to produce submaximal contractions of the uterus equal to those produced by given amounts of the standard substance.

The official biologic assay process and standard for solution of pituitary are as follows:

Solution of Pituitary contains the water-soluble principle or principles from the fresh posterior lobe of the pituitary body of cattle, 1 cc. having an activity upon the isolated uterus of the virgin guinea pig, corresponding to not less than 80 per cent and not more than 120 per cent of that produced by 0.005 Gm. of the Standard Powdered Pituitary, prepared as directed below. The Solution should be sterile.

Assay—Prepare a solution as follows: Carefully weigh a suitable amount of the dried Standard Powdered Pituitary, place this weighed powder in a small agate mortar and moisten with a few drops of distilled water containing 0.25 per cent of acetic acid. Triturate the moistened powder thoroughly until the whole is of an impalpable frothy consistence. Add a few cc. of the 0.25 per cent acetic acid solution and stir the mixture thoroughly. Transfer to a hard glass test tube or beaker; rinse the small agate mortar with the acetic acid solution and add the rinsings to the pituitary mixture; then add enough 0.25 per cent acetic acid to make the final volume of the mixture of the same number of cc. as the number of milligrams of dried pituitary powder originally taken. Heat this mixture to the boiling point for not more than one minute and filter. The filtrate contains in each cc. the active principle of 0.001 Gm. of the dried standard powder. Place this solution in hard glass ampuls and sterilize by fractional sterilization for twenty minutes on three successive days at a temperature not exceeding 100° C. Preserve in a cool place (from 5° to 20° C.). This standard solution should not be kept more than six months.

The apparatus used for making the test may be any modification of the general type for studying the activity of the isolated smooth muscle of mammals. It must be provided with an accurate temperature-regulating device. The chamber in which the uterus is suspended should have a capacity of not less than 100 cc.

Use healthy guinea pigs weighing between 175 Gm. and 350 Gm. They should not have been pregnant and should not be in heat. It is recommended that young female pigs be segregated at the time of weaning and kept thereafter out of sight and smell of the males.

Kill a guinea pig by a blow on the head, or by decapitation, and immediately remove the entire uterus from the body. Suspend a part or all of one horn of the uterus in a chamber containing oxygenated Locke-Ringer solution (page 1547), one end of the uterus being attached to a muscle lever which is weighted as necessary. The temperature of the bath should be between 37° and 38° C. but should not vary more than one-tenth of a degree throughout the whole assay. When the uterus is completely relaxed, which is generally in from fifteen to thirty minutes, it is ready to begin the test. This is done by adding alternately varying doses of the standard extract and of the solution to be tested to the bath in the muscle chamber until quantities of the two solutions are found which give equal, submaximal contractions in at least two successive pairs of contractions. The strengths of the two solutions are in inverse ratio to the quantities necessary to produce these equal contractions.

Standard Powdered Pituitary

Select a number, not less than 25, of fresh posterior lobes of the pituitary body of cattle, removed within thirty minutes of the death of the animal and carefully free them from all extraneous tissue, immediately after their removal. As soon as they are so prepared, drop them into a flask containing a quantity of acetone corresponding to not less than 4 cc. of acetone for each pituitary body. Allow them to remain in the acetone for three hours, and then remove them and immediately cut them into small pieces with scissors and place the material in fresh acetone equal in quantity to that first employed. Leave the material in the acetone overnight, and then remove it and dry it in a vacuum desiccator over calcium chloride, at a temperature not above 50° C., for five hours. At the end of this time remove the material and grind it in a mortar until it will pass through a No. 40 sieve. Dry this powder for at least twelve hours in a vacuum desiccator over calcium chloride at a temperature not over 50° C. Extract this dried powder in a small Soxhlet continuous extraction apparatus with acetone for three hours and again dry it in a desiccator over calcium chloride for twelve hours. This dried powder should be preserved in a cool, dark place, in sealed ampuls *in vacuo*, or in vacuum desiccators over calcium chloride until used for the preparation of the standard solution.

CHAPTER XC

GENERAL TESTS OF THE U.S.P. AND N.F.

Acid Number

The acid number is the number of milligrams of potassium hydroxide required to neutralize the free acid in 1 Gm. of oils, fats, waxes, resins, balsams, and similar organic substances of complex composition. It is determined as follows: Shake about 2 Gm. of the substance, accurately weighed, with from 30 to 50 cc. of neutral alcohol or with a neutral mixture of equal volumes of alcohol and ether, and titrate with half-normal potassium hydroxide, using 1 cc. of phenolphthalein T.S. as indicator.

When the quantity of free acid is small, tenth-normal potassium hydroxide should be used. In place of potassium hydroxide, half-normal or tenth-normal sodium hydroxide may be used for this test, but should be calculated to the equivalent of potassium hydroxide.

Arsenic Test

Test Apparatus—Prepare several generators, equipped with tubes, etc., as described below. Select as a generator a bottle of about 50 cc. capacity, having a mouth about 2.5 cm. in diameter and provide a well-fitting rubber stopper, suitably perforated. Through the perforation insert a vertical exit tube about 13 cm. in total length and 1 cm. in diameter throughout the upper portion (for about 10 cm.) and constricted at its lower extremity to a tube of about 3 cm. in length and about 5 mm. in diameter. This latter tube should extend but slightly below the stopper. In the lower part of the wider exit tube insert a small pledget of dry glass wool (page 1534) and then a strip of freshly prepared but dry lead acetate test paper (page 1547) rolled into a coil, and above this a plug of moist (not wet) lead acetate glass wool (page 1547). In the upper extremity of this tube insert through a perforated cork stopper, a glass tube 12 cm. in length, having an internal diameter of about 3 mm. Place a strip of mercuric bromide test paper (page 1547) in this tube, bending or creasing the upper portion of the strip so that it will retain its position. The strip should extend within about 2 cm. of the perforated cork stopper and must not be introduced into the tube until the test is ready to start. This tube should be thoroughly cleaned and dried each time it is used.

Fig. 541

Arsenic test apparatus

Standard Arsenic Test Solution—Dissolve 0.1 Gm. of arsenic trioxide (page 1530) which has been finely pulverized, dried over sulphuric acid, and accurately weighed, in about 5 cc. of a 20 per cent solution of sodium hydroxide (free from arsenic). Neutralize the solution with diluted sulphuric acid (free from arsenic), add 10 cc. of the same acid and sufficient recently boiled distilled water to bring the volume of the solution to exactly 1000 cc. at 25° C. Accurately measure 10 cc. of this solution, transfer it to a 1000 cc. flask, add 10 cc. of diluted sulphuric acid (free from arsenic) and make up the volume with recently boiled distilled water to exactly 1000 cc. at 25° C. Employ this solution, which contains 0.001 milligram of arsenic trioxide in each cc. (at 25° C.), in preparing the standard stain. Keep this solution in a glass-stoppered bottle. It is advisable to make fresh solutions when new standard stains are to be prepared.

Preparation of the Chemical to be Tested—Add 1 cc. of a mixture of equal volumes of concentrated sulphuric acid (page 1542) and distilled water, to 5 cc. of an aqueous solution of the chemical (1 in 25) or to a solution in 5 cc. of distilled water of the residue remaining after any special treatment that may be directed. This acidulation is not necessary in the case of inorganic acids. Now, unless specially directed, add 10 cc. of sulphurous acid (page 1543). Evaporate this liquid in a small beaker, on a water bath, until it is free from sulphurous acid and has been reduced to about 2 cc. in volume. Dilute this evaporated liquid to about 5 cc. with distilled water.

The Test

Preparation of the Standard Stain—Introduce into the generator from 8 to 10 Gm. of reagent zinc (page 1543) followed by 25 cc. of dilute sulphuric acid, prepared by mixing 1 part of concentrated sulphuric acid, free from arsenic (page 1542), with 4 parts of distilled

water, and 5 drops of acid stannous chloride T.S. (page 1550). Add at once 2 cc. (accurately measured at 25° C.) of the standard arsenic T.S. (page 1512), and immediately insert the stopper containing the exit tube, into which have been placed the glass wool pledget, the dry lead acetate test paper, the moist lead acetate glass wool, and the mercuric bromide test paper, as described under *Test Apparatus* (page 1512). Should the evolution of the gas be violent at first, check the reaction by immersing the bottle in cold water. Should the reaction subside, increase it by placing the bottle in warm water. If the reaction is too violent, the stain will spread and not form a distinctive band, thus making the comparisons of color intensity difficult. After the test has continued for forty-five minutes, remove the mercuric bromide test paper and place it in a clean, dry tube for comparison. This stain represents 0.002 milligram of arsenic trioxide in addition to any stain produced by the reagents. The stain produced by the reagents in a blank test should be scarcely perceptible. Since light, heat, and moisture cause the stain to fade rapidly, comparison should be made as soon as possible. The stained test papers may be preserved by dipping in hot, melted paraffin or by keeping them over phosphoric anhydride, protected from light.

Testing the Chemical—Introduce into another generator from 8 to 10 Gm. of the zinc followed by 25 cc. of the dilute sulphuric acid (1 to 4) and 5 drops of acid stannous chloride T.S. Insert the stopper containing the exit tube in which have been placed the test papers and glass wool, as just described. Then add 5 cc. of the solution to be tested, previously treated as directed under *Preparation of the Chemical to be Tested*, and immediately insert the stopper containing the exit tube. When the evolution of hydrogen has proceeded actively for forty-five minutes, remove the mercuric bromide test paper and carefully compare it with the standard stain prepared as described above. The stain produced by the chemicals tested does not exceed in length or intensity of color that prepared as the standard, indicating not more than 1 part of arsenic trioxide in 100,000 parts of the substance tested.

Interfering Chemicals—Antimony, if present in the substance tested, will produce a gray stain. *Sulphites, sulphides, thiosulphates*, and other compounds which liberate hydrogen sulphide or sulphurous acid when treated with sulphuric acid, must be oxidized by means of nitric acid and then reduced by means of sulphurous acid as directed under *Preparation of the Chemical to be Tested* (page 1512), before introducing them into the apparatus. *Sulphur compounds* as well as *hydrogen phosphide* give a bright yellow band on the test paper. If sulphur compounds are present, a simultaneous darkening of the lead acetate test paper and glass wool will occur. If such is the case, the operation as directed under *Preparation of the Chemical to be Tested* (page 1512) must be repeated upon a fresh portion of the solution being tested, using greater care in effecting the complete removal of the sulphurous acid. In testing hypophosphites special care should be observed to oxidize completely the solution being tested as directed, otherwise a yellow stain may be produced through the evolution of hydrogen phosphide, which might be confused with the orange-yellow color produced by arsenic. The stain produced by hydrogen phosphide is differentiated from that given by arsenic by moistening it with ammonia T.S. A stain caused by arsenic will become dark, but if produced by hydrogen phosphide it will not materially change in color. The test apparatus should be thoroughly cleaned and dried immediately before and after use.

Compounds containing salts of bismuth and antimony should be tested for arsenic by Bettendorf's Test (see below).

Arsenic Test, Bettendorf's

This test for the presence of *arsenic* is employed only in testing salts of bismuth and compounds containing antimony.

To a solution of the prescribed quantity of the substance to be tested in 5 cc. of concentrated hydrochloric acid (page 1534) contained in a clean test tube, add 10 cc. of acid stannous chloride T.S. (page 1550) which has been freshly prepared, and set it aside for thirty minutes. If arsenic is present in non-permissible amounts, a brownish tint or precipitate will be seen when the tube is placed over a white surface and the solution viewed from above, comparison being made with a mixture of 5 cc. of concentrated hydrochloric acid (page 1534 and 10 cc. of concentrated stannous chloride T.S., prepared as directed above.

NOTE—It is absolutely necessary that for this test the solution of stannous chloride be freshly prepared, and that nitrates, sulphates, sulphites, sulphides, and compounds of mercury, gold, and selenium be absent from the reagents, and the chemicals being tested.

Ash or Non-volatile Matter in Chemicals

Weigh accurately from 1 to 2 Gm., or the amount of the chemical directed in the text, and place it in a tared platinum or porcelain crucible. Ignite it, at first very gently, then gradually raise the temperature until any carbon which may be formed is completely burned off. Conduct the ignition in a place protected from air currents and use as low a temperature as possible to effect the combustion of the carbon. When the carbon has

completely disappeared, transfer the crucible while still hot to a desiccator and weigh it when cold. In the case of substances which increase in volume on ignition, or where it is very difficult to burn off the carbon, the determination is facilitated by using a platinum dish of suitable size, or by igniting the weighed quantity of the substance, in the manner described above, in several separate portions.

To test for non-volatile matter in volatile inorganic chemicals, proceed as directed above, using as low a temperature as possible.

Assay for Acids (Alkalimetric)

In assaying acids the quantity of acid to be taken should be such that about 30 to 40 cc. of the alkali solution will be consumed. As a general principle it is recommended that the normality of the acid to be titrated should be approximately the same as that of the titrating medium. Except when otherwise directed, the liquid to be titrated is to be brought to room temperature before titration, as many indicators give different values at different temperatures. For most of the inorganic acids, methyl orange, methyl red, phenolphthalein, or litmus can be used as indicators, but the alkali must be standardized with the particular indicator used. For organic acids, phenolphthalein is always used.

Tare a glass-stoppered flask of about 150 to 200 cc. capacity, pour into it approximately the quantity of acid directed in the text, stopper immediately, and reweigh: the difference represents the quantity of acid taken. Dilute with distilled water to about 40 cc. and titrate with normal sodium hydroxide, using the indicator specified in the text.

In assaying acids which evolve fumes on exposure to air, such as hydrochloric, nitric, and glacial acetic acids, the flask is tared with 10 cc. of distilled water, then the specified quantity of acid is added, the flask immediately stoppered, allowed to cool, and reweighed.

Solid acids are weighed either in a tared glass-stoppered flask or in another suitable container, dissolved in about 40 cc. of distilled water, and titrated.

Assay for Alkali Benzoates and Salicylates

Dry about 2 Gm. of the salt to constant weight at from 100° to 110° C., weigh accurately in a platinum or porcelain crucible, and heat at first gently, then gradually raise the temperature until the salt is thoroughly carbonized. The final temperature must not exceed a dull red heat and the flame of the burner must not come in contact with the carbonized mass. Allow the carbonized mass to cool, disintegrate it well with a stout glass rod or powder carefully, and transfer with the crucible to a beaker or casserole. Add 50 cc. of distilled water and 50 cc. of half-normal sulphuric acid, cover the beaker or casserole with a watch glass, and boil for thirty minutes. Filter and wash the residue with hot distilled water until the washings cease to redden blue litmus paper. Dry the residue and filter paper, and ignite as described above. Transfer the ignited residue to the filtrate, and determine the excess of acid in the cooled filtrate by titration with half-normal sodium hydroxide, using methyl orange T.S. as indicator. The volume of half-normal sulphuric acid consumed, multiplied by the proper equivalent of the salt, represents the amount of the salt present in the quantity taken.

Assay for Alkali Salts of Organic Acids

Heat about 2 Gm. of the salt, accurately weighed, in a platinum or porcelain crucible, heating at first very gently, then gradually raising the temperature until the salt is thoroughly carbonized. (*Caution—Do not use platinum crucibles for lithium salts.*) The final temperature must not exceed a dull red heat and the flame of the burner must not come in contact with the carbonized mass. After allowing the carbonized mass to cool, moisten with distilled water, ignite again, and repeat the moistening and igniting until a white residue is obtained. Then disintegrate the ignited mass with the aid of a stout glass rod and transfer the mass and crucible to a beaker. Add 50 cc. of distilled water and titrate with half-normal sulphuric acid, using methyl orange T.S. as indicator. The number of cc. of half-normal sulphuric acid used, multiplied by the proper equivalent of the salt, represents the amount of salt present in the quantity taken.

Assay for Chlorides, Bromides, and Iodides

Chlorides—Dissolve about 0.2 Gm. of the salt to be assayed, accurately weighed, (corresponding to from 30 to 40 cc. of tenth-normal silver nitrate), in 25 cc. of distilled water in a 200 cc. graduated flask. Add 50 cc. of tenth-normal silver nitrate to the solution, and 5 cc. of nitric acid, then add sufficient distilled water to make 200 cc., and mix well. Filter the mixture through a dry filter into a dry flask, and reject the first 20 cc. of the

filtrate. To 100 cc. of the filtrate add 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth normal potassium thiocyanate until the supernatant liquid remains reddish after it is well shaken. Multiply by 2 the number of cc. of tenth-normal potassium thiocyanate required, and subtract this figure from the number of cc. of tenth-normal silver nitrate added. The difference, multiplied by the equivalent of the respective chloride, represents the amount of chloride present in the weight of the salt or solution taken.

Bromides and Iodides—Dissolve about 0.4 Gm. of the salt if a bromide, or 0.5 Gm. of the salt if an iodide, accurately weighed, in 25 cc. of distilled water in a glass-stoppered flask. Add 50 cc. of tenth-normal silver nitrate to the solution, then 2 cc. of ferric ammonium sulphate T.S. and 2 cc. of nitric acid, and determine the excess of silver nitrate by titrating with tenth-normal potassium thiocyanate until the supernatant liquid remains reddish after it is well shaken. The difference between the number of cc. of tenth-normal silver nitrate added and the number of cc. of tenth-normal potassium thiocyanate used, multiplied by the equivalent of the respective bromide or iodide being assayed, represents the amount of the bromide or iodide present in the weight of the salt taken. This difference, divided by the weight of the salt taken, represents the number of cc. of tenth-normal silver nitrate required by 1 Gm. of the salt.

Electrolytic Determinations

Copper, Mercury, Silver, and Zinc—The electrolytic apparatus consists principally of an ammeter, voltmeter, and rheostat, properly connected with the source of the current, a platinum spiral or disk anode, and a device for rotating the anode. Other suitable apparatus adapted to the use of rotating electrodes may also be employed.

The source of the current may be either storage batteries or any other system of direct current which permits regulation of the voltage and amperage.

Copper and silver are determined in a platinum dish of about 100 cc. capacity which serves as the cathode.

Mercury is determined in a mercury cathode cup, or in a platinum dish which serves as the cathode. The mercury cathode cup consists of a glass cylinder about 6.5 cm. in height and 3.5 cm. in diameter, into which is fused a platinum wire near the bottom, and containing from 50 to 60 Gm. of mercury. The platinum wire must be in contact with the mercury.

For the determination of zinc, a nickel dish of about 175 cc. capacity is used. A platinum dish upon which a thin layer of silver or copper has been previously deposited may also be used.

Cupric Sulphate—Dissolve from 0.75 to 1.0 Gm. of the salt, accurately weighed, in about 100 cc. of distilled water in a weighed platinum dish, add 1 cc. of diluted sulphuric acid, rotate the anode about 500 revolutions per minute and pass the current, gradually increasing it to 2.5 amperes and from 5 to 7 volts. Occasionally add a little distilled water to the electrolyte to keep the deposit of copper covered. When the copper is all deposited (usually in about twenty minutes, to be ascertained by withdrawing a little of the electrolyte and testing it with hydrogen sulphide T.S.), stop the rotation, and wash the deposit with distilled water by means of a siphon without interrupting the current, until the current drops to nearly zero. Remove the dish, wash again with distilled water by decantation, followed by a little alcohol and ether, successively, dry for a few minutes only, at from 80° to 100° C., and weigh.

One gram of Copper is the equivalent of:	Gram
Cupric Sulphate, $CuSO_4 . 5H_2O$	3.9281
Cupric Sulphate, anhydrous, $CuSO_4$	2.5112

Corrosive Mercuric Chloride—Dissolve from 0.3 to 0.4 Gm. of the salt, accurately weighed, in 10 cc. of distilled water and transfer the solution to the cathode cup, which has been previously weighed with its metallic mercury. Dilute the liquid to about 20 cc. with distilled water, add 1 cc. of nitric acid, which has been diluted with an equal volume of distilled water, and 10 cc. of toluene, and pass through the solution a current of from 1 to 3 amperes and from 8 to 12 volts, stirring the solution by rotating the anode from 500 to 600 revolutions per minute. After twenty minutes, when the mercury is all removed from solution (to be ascertained by removing a few drops of the solution and testing with hydrogen sulphide T.S.), wash with distilled water, with the aid of a siphon and without interrupting the current, until the current drops to nearly zero. Remove the cathode cup, wash the mercury with alcohol, then with ether, remove most of the remaining ether with filter paper, dry over sulphuric acid, and weigh. The increase in weight of the cathode cup represents the amount of mercury present in the quantity of the salt taken.

Mercury (Metallic), Mercuric Oxide (Red or Yellow), Mercury with Chalk, and Solution of Mercuric Nitrate—Dissolve an accurately weighed quantity of the substance in a mixture

of equal volumes of nitric acid and distilled water (metallic mercury or mercuric oxide from 0.2 to 0.3 Gm. in 1 cc.; mercury with chalk from 0.6 to 0.8 Gm. in 2.5 cc.), transfer the solution to the cathode cup, which has previously been weighed with its metallic mercury, and dilute with distilled water to about 30 cc. Electrolyze the solution and proceed further as described under *Corrosive Mercuric Chloride*, using a current of from 1.5 to 2 amperes and from 7 to 10 volts.

Ammoniated Mercury, Mild Mercurous Chloride, Mercuric Salicylate, Red Mercuric Iodide, Yellow Mercurous Iodide—Introduce the accurately weighed substance (from 0.5 to 0.6 Gm. of ammoniated mercury or mild mercurous chloride; from 0.7 to 0.8 Gm. of mercuric salicylate or yellow mercurous iodide; from 1.0 to 1.2 Gm. of red mercuric iodide) into the cathode cup, previously weighed with its metallic mercury, add 10 cc. of solution of sodium sulphide (made by dissolving 50 Gm. of crystallized sodium sulphide in sufficient distilled water to measure 100 cc.) and dissolve as completely as possible by agitation. Dilute the mixture to about 30 cc. with distilled water and pass through the solution a current of from 2 to 3 amperes and from 7 to 10 volts for thirty minutes (or until a few drops of the liquid do not give a black precipitate or coloration when gently warmed with a few drops of concentrated ammonium chloride solution), stirring the solution by rotating the anode about 500 revolutions per minute. Wash the mercury, and proceed as described under *Corrosive Mercuric Chloride*, except that before washing with alcohol allow it to stand with about 20 cc. of dilute acetic acid (from 2 to 3 per cent) until bubbles cease to be evolved.

One gram of Mercury is the equivalent of:	Gram
Ammoniated Mercury, $HgNH_2Cl$	1.2566
Mercuric Chloride, Corrosive, $HgCl_2$	1.3535
Mercurous Chloride, Mild, $HgCl$	1.1768
Mercuric Iodide, Red, HgI_2	2.2654
Mercurous Iodide, Yellow, HgI	1.6327
Mercuric Nitrate, $Hg(NO_3)_2$	1.6182
Mercuric Oxide (Red or Yellow), HgO	1.0798
Mercuric Salicylate, $HgC_7H_4O_3$	1.1798

Silver Nitrate—Powder the salt, dry it to constant weight over sulphuric acid in the dark, dissolve from 0.3 to 0.5 Gm., accurately weighed, in about 35 cc. of distilled water in a tared platinum dish, add a solution of 2 Gm. of sodium cyanide in 10 cc. of distilled water, rotate the anode about 500 revolutions per minute, and pass a current, gradually increased to 2.5 amperes and from 5 to 7 volts. After the silver is all deposited (usually from twenty to thirty minutes, to be ascertained by withdrawing a small quantity of the electrolyte and testing it with hydrochloric acid), interrupt the current, wash the deposit of silver several times with distilled water, rinse with a little alcohol, then with ether, dry the dish at from 80° to 100° C. for a few minutes, and weigh.

Molded Silver Nitrate—Dissolve from 0.3 to 0.5 Gm., accurately weighed, in 10 cc. of distilled water, filter through a small filter paper, wash the paper with distilled water until free from silver nitrate, bring the combined filtrate and washings to a volume of about 35 cc. in a tared platinum dish, add a solution of 2 Gm. of sodium cyanide in 10 cc. of distilled water, and proceed with the determination as under *Silver Nitrate*.

One gram of Silver is the equivalent of:	Gram
Silver Nitrate, $AgNO_3$	1.5748
Silver Oxide, Ag_2O	1.0742

Zinc (Metallic), Zinc Acetate, Zinc Carbonate, Zinc Chloride, Zinc Oxide, Zinc Phenolsulphonate, Zinc Sulphate—Introduce into a tared nickel dish, an accurately weighed quantity of the salt, equivalent to about 0.15 Gm. of metallic zinc (zinc acetate, 0.5 Gm., zinc carbonate, 0.25 Gm.; zinc chloride, 0.3 Gm., zinc oxide, 0.2 Gm.; zinc phenolsulphonate, 1.2 Gm.; zinc sulphate, 0.6 Gm.); dissolve it in distilled water or in 10 cc. of diluted sulphuric acid (zinc carbonate, zinc oxide), add from 30 to 35 cc. of sodium hydroxide solution (20 per cent), and dilute with distilled water to about 120 cc. Heat the mixture nearly to boiling and electrolyze for thirty minutes with a current of from 4 to 5 amperes and from 5 to 6 volts, stirring the solution by rotating the anode from 500 to 600 revolutions per minute. Without interrupting the current, wash the deposited zinc with distilled water with the aid of a siphon until the current drops to zero or nearly so. Remove the dish, wash the zinc first with alcohol, then with ether, dry over sulphuric acid, and weigh. The increase in weight of the dish represents the amount of zinc present in the weight of the salt taken.

To determine zinc in metallic zinc, weigh accurately about 1.5 Gm. of the metal, dissolve

it by warming with 40 cc. of diluted sulphuric acid, filter the solution, if necessary, wash the filter well with distilled water, and make up the volume of the solution and washings to 100 cc. Measure 10 cc. of this liquid into the weighed dish and proceed as directed above.

One gram of Zinc is the equivalent of:	Gram
Zinc Acetate, $Zn(C_2H_3O_2)_2.2H_2O$	3.3570
Zinc Chloride, $ZnCl_2$	2.0849
Zinc Oxide, ZnO	1.2448
Zinc Phenolsulphonate, $Zn(C_6H_5SO_4)_2.8H_2O$	8.5011
Zinc Sulphate, $ZnSO_4.7H_2O$	4.3988
Zinc Sulphate, anhydrous, $ZnSO_4$	2.4695

Ester Number

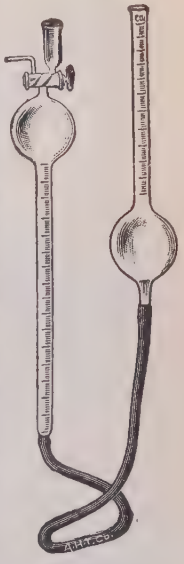
The ester number is the number of milligrams of potassium hydroxide required to saponify the esters in 1 Gm. of oils, fats, waxes, resins, balsams, and similar organic substances of complex composition. If the saponification value and the acid number have been determined, the difference between these two represents the ester number.

The ester number is also determined directly as follows: Shake from 1.5 to 2 Gm. of the substance, accurately weighed, in a 200 to 250 cc. tared flask, with from 20 to 30 cc. of alcohol, add 1 cc. of phenolphthalein T.S., and titrate with half-normal alcoholic potassium hydroxide until the free acid is neutralized. Add exactly 25 cc. of half-normal alcoholic potassium hydroxide, and proceed as directed under *Saponification Value*, beginning with "Insert in the neck of the flask" and omitting the further addition of phenolphthalein T.S. The difference in the number of cc. of half-normal hydrochloric acid consumed in the actual test and in the blank, multiplied by 28.06 and divided by the weight of the substance taken, gives the ester number.

Gasometric Estimations

In certain cases the Pharmacopœia directs the strength of a product or chemical substance to be determined by the volume of gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the use of a nitrometer (see Fig. 542) in the following manner:

Fig. 542



Nitrometer

By means of clamps attached to a stand, arrange a nitrometer consisting of a measuring tube (having a capacity of at least 50 cc. and graduated into one-tenth cc.) connected by stout rubber tubing with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end) in such a manner, that either tube may be readily adjusted and quickly clamped at a higher or lower level. The stopcock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium choride, until the measuring tube, including the bore of the stopcock, is completely filled. Then close the latter and adjust the equilibrium tube at a low level. Having ascertained that the stopcock is closed and is air-tight, and having, if necessary, wiped out the graduated tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it successively with the prescribed quantities of potassium iodide T.S. and normal sulphuric acid. When the reaction moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than that in the equilibrium tube, shake its contents without permitting any gas to pass into the open tube. When the reaction has completely ceased and the volume of gas has become constant, which usually requires from thirty to sixty minutes, restore the tube to its fastening, and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be close to 25° C. Then adjust the two tubes so that the liquid columns are at exactly the same level, and read the volume of gas in the measuring tube. Multiply this figure by the weight of the liquid being assayed which is the equivalent of 1 cc. of nitrogen dioxide (page 1518). The result will be the weight of the absolute substance (ethyl, amyl, or sodium nitrite) contained in the quantity taken for the assay.

For pharmacopœial purposes, the determination will be sufficiently exact if the evolved gas is measured within 3° above or below 25° C.

Since temperature and barometric pressure affect the volume of the gas, the following correction factors must be used to obtain exact results when the temperature and pressure vary from the normal. The barometric correction is important at any locality more than 250 meters above sea level:

FACTORS FOR TEMPERATURE CORRECTIONS

(Normal Temperature, 25° C.)

Temperature	Factor	Temperature	Factor	Temperature	Factor
15° C.	1.035	22° C.	1.010	29° C.	0.987
16° C.	1.031	23° C.	1.007	30° C.	0.983
17° C.	1.028	24° C.	1.003	31° C.	0.980
18° C.	1.024	25° C.	1.000	32° C.	0.977
19° C.	1.021	26° C.	0.997	33° C.	0.974
20° C.	1.017	27° C.	0.993	34° C.	0.971
21° C.	1.014	28° C.	0.990	35° C.	0.968

Example: Assuming that the volume of gas read off was 44.5 cc. at 32° C., and it is desired to ascertain the corresponding volume at 25° C., barometric pressure not being taken into consideration, then the 44.5 cc. must be reduced in the proportion of 1 to 0.977 (see temperature correction factors above), or 44.5 must be multiplied by 0.977. The result will be 43.48 cc. as the equivalent volume of gas at 25° C.

FACTORS FOR CORRECTION FOR BAROMETRIC PRESSURE

(Normal Barometer, 760 mm.)

Barometer Reading		Factor	Barometer Reading		Factor
Millimeters	Inches		Millimeters	Inches	
790	31.10	1.039	660	25.98	0.868
780	30.71	1.026	650	25.59	0.855
770	30.31	1.013	640	25.20	0.842
760	29.92	1.000	630	24.80	0.829
750	29.53	0.987	620	24.41	0.816
740	29.13	0.974	610	24.02	0.803
730	28.74	0.961	600	23.62	0.789
720	28.35	0.947	590	23.23	0.776
710	27.95	0.934	580	22.83	0.763
700	27.56	0.921	570	22.44	0.750
690	27.17	0.908	560	22.05	0.737
680	26.77	0.895	550	21.65	0.724
670	26.38	0.882	540	21.26	0.711

Example: Assuming that the volume of gas read off was 43.48 cc. at 590 mm. barometric pressure, and it is desired to ascertain the corresponding volume at normal barometric pressure (760 mm.), temperature not being taken into consideration, then the 43.48 cc. must be reduced in the proportion of 1 to 0.776 (see barometric correction factors above), or 43.48 must be multiplied by 0.776. The result will be 33.74 cc. as the equivalent volume of gas at normal barometric pressure.

FACTORS FOR DETERMINING NITRITES

NO = 30.01; 1 Liter { at 0° C. and 760 mm. = 1.3406 Gm.
at 25° C. and 760 mm. = 1.2281 Gm.

One cubic centimeter of Nitrogen Dioxide is the equivalent of:

		At 0° C. and 760 mm. Gram	At 25° C. and 760 mm. Gram
Nitrogen Dioxide, NO =	30.01	0.0013406	0.0012281
Amyl Nitrite, $C_5H_{11}NO_2$ =	117.10	0.0052310	0.0047920
Ethyl Nitrite, $C_2H_5NO_2$ =	75.05	0.0033528	0.0030713
Sodium Nitrite, $NaNO_2$ =	69.01	0.0030828	0.0028241

Heavy Metals Test

Chemicals—This test is to be used to detect the presence of undesirable metallic impurities in official chemical substances or their solutions. Acidulate 10 cc. of a solution of the substance in distilled water (1 in 50), contained in a test tube of about 25 cc. capacity and about 2 cm. in diameter, with 1 cc. of diluted hydrochloric acid (unless otherwise directed),[1] warm it to about 50° C., add an equal volume of freshly prepared hydrogen sulphide T.S., stopper, and allow the mixture to stand at 35° C. for half an hour. At the end of this time the mixture should still possess the odor of hydrogen sulphide; if not, it should be thoroughly saturated with the gas and again set aside for half an hour. The color produced, if any, is not greater than that observed in a blank test made in the same manner and with the same quantities of the reagents (omitting the solution to be tested), the solutions being viewed crosswise by reflected light while held against a white surface. A slight turbidity due to separation of sulphur from the hydrogen sulphide may occur. Filter the solution if necessary and render it alkaline by the addition of ammonia T.S.: a greenish color may be produced but no precipitate is formed within one minute. The addition of ammonia T.S. is omitted in testing salts which produce precipitates when ammonia is added to their solutions.

Volatile Oils—Shake 10 cc. of the oil with an equal volume of distilled water to which a drop of hydrochloric acid has been added, and pass hydrogen sulphide through the mixture until it is saturated: no darkening in color is produced in either the oil or the water (*lead or copper*).

Iodine Value

The iodine value or number of a fat or oil indicates the proportion of iodine absorbed under specified conditions. It is determined as follows: Introduce about 0.8 Gm. of a solid fat or about 0.3 Gm. of an oil, accurately weighed, into a glass-stoppered bottle of 250 cc. capacity, dissolve it in 10 cc. of chloroform, add 25 cc. of iodobromide T.S. (page 1546) accurately measured from a burette or pipette, stopper the bottle securely, and allow the mixture to stand for half an hour in a cool place protected from light. After this time it must still retain a brown color; if the color is not brown, a new test should be started, using a smaller quantity of the fat or oil. Then add in the order named 30 cc. of potassium iodide T.S., 100 cc. of distilled water, and tenth-normal sodium thiosulphate in small successive portions, shaking thoroughly after each addition, until the color of the mixture becomes quite pale. Now add a few drops of starch T.S. and continue the addition of tenth-normal sodium thiosulphate until the blue color is discharged. While this test is being carried out, make a blank test by mixing exactly the same quantities of reagents and titrate the free iodine with tenth-normal sodium thiosulphate as directed above. The difference in the number of cc. of tenth-normal sodium thiosulphate consumed by the blank test and the actual test, multiplied by 1.269 and divided by the weight of the fat or oil taken, gives the iodine value.

Rosin Test

For testing for rosin as an adulterant in resins, gum resins, and balsams, place in a small mortar 1 Gm. of the substance, powdered or crushed if necessary, and add 10 cc. of purified petroleum benzin unless the substance contains free cinnamic or benzoic acid, in which cases the petroleum benzin should be replaced by xylene. Triturate well for one or two minutes, filter into a test tube, and add to the filtrate 10 cc. of a fresh aqueous solution of copper acetate (1 in 200). Shake well and allow the liquids to separate: the benzin or xylene layer should not show a green color (*rosin*).

Saponification Value

The saponification value is the number of milligrams of potassium hydroxide required to neutralize the free fatty acids and saponify the esters of 1 Gm. of a fat, oil, wax, etc. It is determined as follows: Place from 1.5 to 2 Gm. of the filtered fat or oil, accurately weighed, in a flask of from 200 to 250 cc. capacity and add to it exactly 25 cc. of alcoholic half-normal potassium hydroxide (page 1558). Insert into the neck of the flask, by means of a perforated stopper, a glass tube from 70 to 80 cm. in length and from 5 to 8 mm. in diameter, and heat the flask on a water bath for half an hour, frequently rotating the contents. Then add 1 cc. of phenolphthalein T.S. and titrate the excess of potassium hydroxide with half-normal hydrochloric acid. Make a blank test at the same time, using exactly the same amount of alcoholic half-normal potassium hydroxide. The difference in

[1] Acids are first carefully neutralized by the addition of ammonia T.S. and then acidified as directed above.

the number of cc. of half-normal hydrochloric acid consumed in the actual test and in the blank, multiplied by 28.06 and divided by the weight of the fat or oil taken, gives the saponification value.

Turbidimetric Tests

These tests are applied to certain official chemicals, to insure the absence of excessive amounts of chloride or sulphate.

In carrying out these turbidimetric tests, the following points are to be observed: The same quantities of the same reagents must be used in the test of the substance under examination and in the control test. The glass cylinders in which the tests are made must be of the same diameter and match in all other respects as closely as possible. The precipitating reagent must be added to both in immediate sequence.

Chloride—The prescribed quantity of the substance to be tested is dissolved in from 30 to 40 cc. of distilled water, and the solution neutralized, if necessary, with nitric acid, using litmus paper as indicator. One cc. of nitric acid and 1 cc. of silver nitrate T.S. are added and then sufficient distilled water to make 50 cc. After mixing well and allowing to stand five minutes protected from direct sunlight, the turbidity, if any, is compared with that produced in a control test made with the specified volume of fiftieth-normal hydrochloric acid.

Bismuth Salts are first dissolved in a few cc. of distilled water and 2 cc. of nitric acid, then diluted with distilled water to 50 cc.

Sulphate—The specified quantity of the substance to be tested is dissolved in from 30 to 40 cc. of distilled water, and the solution neutralized, if necessary, with hydrochloric acid, using litmus paper as indicator. One cc. of diluted hydrochloric acid and 1 cc. of barium chloride T.S. are added and then sufficient distilled water to make 50 cc. After mixing well, it is allowed to stand for ten minutes and the turbidity, if any, is compared with that produced in a control test made with the specified volume of fiftieth-normal sulphuric acid.

If the solution, after the addition of acid, is not perfectly clear, it is filtered through a filter paper free from chloride or sulphate, then the silver nitrate or the barium chloride is added.

In applying the turbidimetric tests to salts of heavy metals, which normally show an acid reaction, their aqueous solutions prepared for the test are not to be neutralized.

When the tests for chloride or sulphate are to be applied to a specified volume of a solution of a substance prepared as directed in the text, and the permissible limit for these impurities corresponds to 0.2 cc. or less of fiftieth-normal hydrochloric or sulphuric acid, the solution is not to be further diluted. The control test is also made with the same volume of water (or other specified solvent) as in the test.

Unsaponifiable Matter

The term "unsaponifiable matter" is understood to mean substances present in oils or fats that are not saponifiable by caustic alkali and are insoluble in water. It is determined as follows: Heat 5 Gm. of the oil or fat under a reflux condenser with a solution of about 2 Gm. of potassium hydroxide in 40 cc. of alcohol for an hour or until completely saponified. Evaporate most of the alcohol, dissolve the residue in 50 cc. of hot distilled water, and transfer the solution to a separator, rinsing the flask with 25 or 50 cc. of hot distilled water. Cool, and shake with two successive portions of 50 cc. each of ether, adding a few cc. of alcohol to facilitate the separation of the two liquids. Wash the combined ether extract with small portions of distilled water until the water is not reddened by phenolphthalein T.S. Transfer the ether solution to a tared dish or beaker, evaporate the ether on a water bath, dry the residue at a temperature not exceeding 100° C., and weigh.

Vegetable Drugs, Sampling and Analysis

Sampling from Original Containers

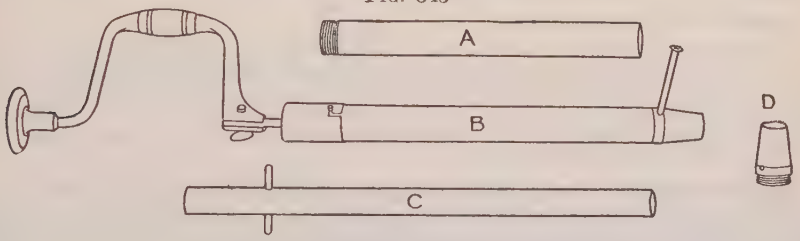
I. It is recommended that gross samples of vegetable drugs in which the component parts are 1 cm. or less in any dimension, and all powdered or ground drugs, be taken by means of a sampler which removes a core from the top to the bottom of the container, not less than two cores being taken in opposite directions; that when the total weight of the drug to be sampled is less than 100 kilos (200 pounds), at least 250 Gm. shall constitute an *official sample;* that when the total weight of the drug to be sampled is in excess of 100 kilos, repeated samples shall be taken by the above method, and according to the schedule given below, mixed and quartered, two of the diagonal quarters being rejected, the remaining two quarters being combined and carefully mixed, and again subjected to a quartering

process in the same manner until two of the quarters weigh at least 250 Gm., which latter shall constitute an *official sample.*

The apparatus illustrated in Fig. 543 was proposed by L. J. Schwarz and has been used at the New York Food and Drug Inspection Station of the Bureau of Chemistry. The sampling procedure is very simple and resolves itself into cutting out the desired number of cores from the drug to be sampled. As each core is cut, the end cap is released and the drug column in the sampler is forced into a suitable receiver by means of the wooden plunger (*C*). The work is not difficult. Even a novice at sampling is capable of doing the work properly, and, moreover, the bag or bale from which the sample has been taken will suffer no damage. Another point of interest in this connection is that the sample taken does not make the identification of the drug more difficult because the material is not mangled and the diameter of the drill insures pieces of sufficient size. Some drugs require the cutter fitted with a saw edge (*D*).

II. It is recommended that gross samples of vegetable drugs in which the component parts are over 1 cm. in any dimension be taken by hand; that when the total weight of the drug to be sampled is less than 100 kilos, at least 500 Gm. shall constitute an *official sample,* and this shall be taken from different parts of the container or containers; that when the total weight of the drug to be sampled is in excess of 100 kilos, repeated samples shall be taken by the above method and according to the schedule below, mixed and quartered, two of the diagonal quarters being rejected, and the remaining two quarters being combined

FIG. 543



Sampler for drugs in bales

and carefully mixed, and again subjected to a quartering process in the same manner until two of the quarters weigh not less than 500 Gm., which latter quarters shall constitute an *official sample.*

SCHEDULE RECOMMENDED FOR SAMPLING

Number of packages in shipment	Number of packages to be sampled
1 to 10	1 to 3
10 to 25	2 to 4
25 to 50	3 to 6
50 to 75	6 to 8
75 to 100	8 to 10

When over 100, the total number sampled should not be less than 10.

III. When the total weight of a drug to be sampled is less than 10 kilos, it is recommended that the above methods be followed but that somewhat smaller quantities be withdrawn, and in no case should the final *official sample* weigh less than 125 Gm.

IV. In addition to the withdrawing of *official samples* according to methods I, II, and III, the *official sample* may consist of the total amount of a direct purchase made by Federal, State, or Municipal Food and Drugs Act enforcement officials.

Foreign Organic Matter in Whole Vegetable Drugs.

V. Withdraw from 25 to 500 Gm. from the *official sample,* spread out in a thin layer, and separate the foreign organic matter by hand as completely as possible. Weigh and determine the per cent of foreign organic matter, calculated upon the weight of drug taken. The maximum quantity should be used for coarse or bulky drugs.

Preparation of Vegetable Drugs for Analysis.

VI. The following method is to be used where specific directions are not otherwise given in the text: Withdraw as much as may be necessary of the *official sample* by quartering, taking pains to see that the portion is representative of the gross sample. In the case of

unground or unpowdered drugs, grind the withdrawn sample so that it will pass through a No. 20 standard-mesh sieve. If the sample cannot be ground, reduce it to as fine a state as possible. Mix by rolling it on paper or sampling cloth, spread it out in a thin layer and withdraw the portion for analysis.

Total Ash in Vegetable Drugs.

VII. Accurately weigh a quantity of the ground drug, representing from 2 to 4 Gm. of the air-dried material, in a tared crucible, and incinerate at a low temperature, not to exceed very dull redness, until free from carbon, and determine the weight of the ash. If a carbon-free ash cannot be obtained in this way, exhaust the charred mass with hot distilled water, collect the insoluble residue on an ashless filter paper, incinerate the residue and filter paper until the ash is white or nearly so, then add the filtrate, evaporate it to dryness; and heat the whole to a low redness. If a carbon-free ash cannot be obtained in this way, cool the crucible, add 15 cc. of alcohol, break up the ash with a glass rod, burn off the alcohol, and again heat the whole to a low redness. Finally determine the weight of the ash. Calculate the percentage of total ash from the weight of the drug taken.

Acid-insoluble Ash in Vegetable Drugs.

VIII. Boil the ash obtained under paragraph VII with 25 cc. of diluted hydrochloric acid for five minutes, collect the insoluble matter in a Gooch crucible or on an ashless filter, wash with hot distilled water, ignite, and weigh. Determine the per cent of acid-insoluble ash calculated from the weight of drug taken.

Moisture in Vegetable Drugs.

IX. *Preparation of Sample*—In the case of unground or unpowdered drugs, prepare about 10 Gm. of the *official sample* by cutting, granulating, or shredding, so that the parts are about 3 mm. in thickness. Seeds or fruits smaller than 3 mm. should be cracked. High-speed mills should not be used for preparing the sample and care should be taken that no appreciable amount of moisture is lost during the preparation, and that the portion taken is representative of the *official sample.*

Moisture Method for Drugs Containing no Constituents Volatile at 100° C.

X. Accurately weigh about 10 Gm. of the drug as prepared under paragraph IX in a tared evaporating dish. Dry at a temperature of 100° C. for five hours and weigh. Continue the drying and weighing at one hour intervals until the loss is not more than 0.25 per cent in one hour's drying.

Moisture Method for Drugs Containing Ether-soluble Constituents Volatile at 100° C.

XI. Proceed as under paragraph X. Determine the volatile ether-soluble extractive (paragraph XIII) and subtract the percentage of volatile ether-soluble extractive from the percentage lost during drying. The difference represents the percentage of moisture.

Crude Fiber.

XII. Exhaust a weighed quantity of the prepared drug (paragraph VI), representing about 2 Gm. of the drug, with ether or use the residue from the determination of the volatile ether-soluble extractive (paragraph XIII). Add 200 cc. of boiling sulphuric acid solution adjusted to exactly 1.25 per cent by titration, to the ether-exhausted drug, in a 500 cc. flask, and connect the flask with a reflux condenser, the tube of which passes only a short distance below the rubber stopper, into the flask. Heat the mixture to boiling and continue the boiling exactly thirty minutes. Then filter the mixture through a filter and wash the residue on the filter with boiling distilled water until the washings are no longer acid. Rinse the residue back into the flask with 200 cc. of boiling sodium hydroxide solution, adjusted to exactly 1.25 per cent by titration and free from sodium carbonate. Again heat the mixture to boiling and continue the boiling exactly thirty minutes under the reflux condenser as described under the treatment with acid, then rapidly filter through a tared filter, wash the residue with boiling distilled water until the washings are neutral, dry it at 110° C. until of constant weight, and note the weight. Now completely incinerate the dried residue and weigh the ash: the loss of weight is considered to be the weight of the crude fiber.

NOTE—The boiling with acid and alkali should continue *exactly* thirty minutes from the time that the liquid (which is cooled below the boiling point by adding it to the cold flask) again boils. After the solution has been brought to boiling, the flame should be turned low enough just to maintain boiling. During the boiling the flask should be gently rotated from time to time to catch any particles which may adhere to the walls of the flask. A slow current of air introduced into the flask during the boiling operation will be very helpful to keep down excessive frothing.

Volatile Ether-soluble Extractive.

XIII. Extract completely 2 Gm. of the prepared drug (paragraph VI), dried over sulphuric acid for not less than twelve hours, by subjecting it, during twenty hours, to the action of dehydrated ether (page 1533) in continuous extraction apparatus. Transfer the ethereal solution to a tared porcelain dish and allow it to evaporate spontaneously. Then dry it over sulphuric acid during eighteen hours and weigh the total ether extract. Now heat the extract gradually up to 110° C. until the weight becomes constant: the loss in weight during the heating represents the volatile portion of the extract.

Non-volatile Ether-soluble Extractive.

XIV. Proceed as directed under *Volatile Ether-soluble Extractive* (paragraph XIII). The weight of the extract after drying in a desiccator and then at 110° C. until of constant weight represents the non-volatile portion of the extract.

Alcohol-soluble Extractive.

XV. Macerate about 2 Gm. of the prepared drug (paragraph VI), accurately weighed, in about 70 cc. of alcohol in a suitable flask. Shake during eight hours at thirty minute intervals and allow to stand for sixteen hours without shaking. Filter and wash the flask and residue with small portions of alcohol until the filtrate measures 100 cc. Evaporate a 50 cc. aliquot portion to dryness in a suitable tared dish on a water bath and dry to constant weight at 110° C. Calculate the percentage of anhydrous extractive from the weight of drug taken.

Diluted Alcohol-soluble Extractive.

XVI. Proceed as directed under paragraph XV, using diluted alcohol instead of alcohol.

Water-soluble Extractive.

XVII. Proceed as directed under paragraph XV, using distilled water instead of alcohol.

Extractive, Soluble in Purified Petroleum Benzin.

XVIII. Extract completely about 2 Gm. of the prepared drug (paragraph VI), accurately weighed, by subjecting it during twenty hours to the action of purified petroleum benzin in a continuous extraction apparatus. Transfer the benzin solution to a tared porcelain dish and allow it to evaporate spontaneously. Then dry it over sulphuric acid for eighteen hours and weigh. Calculate the percentage of anhydrous extractive from the weight of drug taken.

CHAPTER XCI

PHYSICAL CONSTANTS

Boiling and Distilling Points

THESE are described on page 120.

Congealing Points

Unless otherwise directed, about 10 cc. of the liquid to be tested is introduced into a dry test tube of from 18 to 20 mm. internal diameter, which is then cooled in water or in a suitable freezing mixture, the temperature of which should be about 5° lower than the supposed congealing point of the liquid. To induce crystallization, rub the walls of the tube with a standard thermometer (page 106), or add a small crystal of the substance being tested. By alternated immersion of the tube in the bath, or removal from the bath and constant stirring with the thermometer, the temperature is so adjusted that the greater part of the liquid gradually congeals. The highest temperature remaining constant for a short time during the congelation is defined as the congealing point.

Melting Points

These are described on page 106.

Optical Rotation

In a ray of ordinary light the transverse vibrations take place indifferently in any plane about the line of propagation. When these waves are limited to a single plane, they are termed polarized and the phenomenon is known as polarization.

Many organic substances, either liquid or in solution in suitable solvents, when examined in a specially constructed optical apparatus called a polariscope, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active", and when rotating to the right, are designated as "dextrorotatory" and when rotating to the left, as "lævorotatory". Substances which do not possess this property of optical rotation are termed "optically inactive". Optical activity in many instances is intimately connected with the chemical constitution of a substance, frequently becoming a specific property, and its determination is of considerable value.

Among the substances recognized in the Pharmacopœia, there are a number, particularly certain essential or volatile oils and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for polariscopic tests, vary in their construction and are classified as polarimeters (measuring angular rotation) and saccharimeters (measuring percentage of sucrose). Those which are most generally adapted for the examination of the substances mentioned above are the penumbral or so-called "half-shadow" instruments of Laurent and of Schmidt and Hänsch in which the two sides of the field of vision are capable of becoming unequally illuminated. Polarimeters permit the angle of rotation to be read off in degrees or fractions of a degree of a circle. Saccharimeters, set to measure percentage of sucrose, give readings in terms of divisions of the sugar scale.

These determinations are best made in a dark room, and by means of monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

The following factors are employed for converting readings of a saccharimeter into readings of a polarimeter.

1 division Laurent sugar scale equals 0.2167° angular rotation D.

1 division Schmidt and Hänsch sugar scale equals 0.346° angular rotation D.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is essential that the observations should be made with tubes of a definite length, such as 200, 100, 50, or 25 mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the magnitude of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1, and in a tube having a length of 1 decimeter (100 mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[a]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number. The temperature used in the text of the Pharmacopœia is 25° C., except when otherwise indicated. For saccharimeters the temperature is fixed at 20° C. by international agreement.

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

$$\text{I. For liquid substances} \quad [a]_D = \frac{100 \times a}{L \times d}$$

$$\text{II. For solutions of solids} \begin{cases} [a]_D = \dfrac{10000 \times a}{L \times p \times d} \\ \text{or} \quad [a]_D = \dfrac{10000 \times a}{L \times c} \end{cases}$$

For calculating these formulas, the determination of the following factors is necessary:
a = the angle of rotation of the liquid or solid observed with sodium light.
L = the length of the tube in millimeters.
d = the density of the active liquid or solution.
p = the amount of active substance in 100 parts by weight of the solution.
c = the number of grams of active substance in 100 cc. of solution.

Refractive Index

When a ray of light passes from one transparent substance into another of different density, it is deflected, except when it enters perpendicularly to the surface of contact. The direction of the deviation is dependent upon the difference of density of the two substances; the extent is also influenced by this difference.

This deviation is termed "refraction". When the ray passes from a substance of given density to one of greater density (*e.g.*, from air into glass) the refraction is towards the perpendicular meeting the surface at the point of contact; when passing from a substance of greater density to one of less (*e.g.*, from water into air) the ray deviates from the perpendicular at the point of contact.

Quantitative measurements of refraction are expressed as "indices of refraction", the index being the figure obtained by dividing the sine of the angle that the incident ray makes with the perpendicular, by the sine of the angle that the refracted ray makes with the same perpendicular; that is, it is the ratio between these sines. Thus, the ratio for a ray of light passing from air into water at standard temperature is about 4 : 3 or, expressing it decimally and with greater exactness, 1.336. This is, therefore, the index of refraction of water. The determination of the refractive index is accomplished by means of optical instruments known generally as *refractometers*, which are of several types. Some of these give figures on an arbitrary scale, the actual refractive index being ascertained by consulting a table.

As the exact temperature at which the examination is made is of great importance, all of the instruments are provided with attachments for circulating water of the proper temperature about the prisms or about the vessel containing the liquid to be observed, and are also equipped with thermometers for observing the temperature very closely.

The principal instruments in use are as follows:

Pulfrich Refractometer—This instrument is used chiefly for purely scientific investigations. It is adapted for use with liquids and solids of all degrees of refractive power. When a liquid is to be examined, it is placed in a small cylindrical glass vessel immediately above the observation prism. When solids are to be examined, the glass cylinder is removed and the solid (previously polished) is placed in direct contact with the observation prism. The reading of this instrument is made by noting a boundary line between a light and a dark field in its position with reference to a graduated scale upon which the refractive index is directly expressed.

The Abbe Refractometer—This is an instrument of wide utility, designed primarily for the examination of liquids. Only a few drops of the liquid are required for an observation. This is spread in a thin film between the two observation prisms. The index of refraction

is also read off directly upon the scale of this instrument, in which, as in the Pulfrich refractometer, a boundary line between a light and a dark field is the observation line.

The Zeiss Butyro Refractometer—This instrument is especially designed for the examination of fixed oils and fats. It is not applicable to aqueous or alcoholic liquids. The distinctive line for observation in this instrument is the border line of total reflection which is a narrow line capable usually of being accurately read to within a tenth of a unit of the arbitrary scale used. Sometimes this observation line is accompanied by a blue or a red fringe or haze which interferes with the accuracy of the reading. Should a close reading be impossible on this account, it will be found necessary to use the monochromatic sodium flame for the observation (see under optical rotation).

Zeiss Immersion Refractometer—This is adapted for the examination of aqueous, oily, or alcoholic liquids. The distinctive line for observation is as described under the preceding instrument, the border line of total reflection in this case being much sharper and capable of being more accurately read.

For making observations of the entire range of pharmacopœial substances, the Abbe instrument is the one generally selected, the Pulfrich instrument not being in common use, and the Zeiss butyro- and immersion refractometers not covering the entire range necessary.

Solubility

This is described on page 182.

Specific Gravity

This is described on page 57.

Viscosity

Viscosity is a term used to denote the relative degree of fluidity of a liquid. Scientifically, viscosity may be defined as the force which will move a unit area of plane surface, with unit speed relative to another parallel plane surface, from which it is separated by a layer of the liquid of unit thickness. The viscosity of a liquid varies with the temperature, the higher the temperature the lower the viscosity and *vice versa*.

Several methods of expressing viscosity are in use. The method adopted in this Pharmacopœia is "kinematic viscosity" which is based on absolute viscosity. The kinematic viscosity is the ratio of the absolute viscosity expressed in poises over the density $\left(\frac{\mu}{\gamma}\right)$. The poise is the unit of absolute viscosity and is equivalent to the force of one "dyne-second per square centimeter".

As a poise is rather large, one-hundredth of a poise, or a centipoise (cp.), is now generally accepted as a more convenient unit for absolute viscosity. The centipoise is almost exactly the viscosity of water at 20° C.

Methods of determining absolute or kinematic viscosity are described in the U. S. Bureau of Standards papers S–298, T–100, and T–112. Instead of the direct determination of absolute or kinematic viscosity which is rather difficult, the viscosity may be determined with either the Engler or Saybolt viscosimeters and the results obtained with these instruments converted into the kinematic viscosity with the aid of the conversion tables given below.

In the Engler instrument, viscosity is expressed in "Engler degrees". These are obtained by dividing the time of discharge for the liquid being tested by the time of discharge for water at 20° C.

With the Saybolt Universal Viscosimeter, results are expressed as the time of discharge, in seconds, of the liquid being tested. In the United States the Saybolt Universal Viscosimeter is generally used for the determination of viscosity of lubricating oils. This instrument, in brief, consists of a metallic cylinder to contain the liquid under examination and having an outlet in the bottom closed with a cork stopper. It is surrounded with a jacket which serves as a bath to heat the liquid under examination to the specified temperature, the jacket being provided with facilities for stirring and heating the bath. Thermometers, a flask graduated at 60 cc., and a stop watch accompany the apparatus.

To determine the viscosity, the bath is first filled with a suitable liquid, and heated to a few degrees above the temperature at which the test is to be made, then the cylinder is filled with the liquid under examination, and when the liquid in the cylinder registers the specified temperature, adjust the volume, place the flask, graduated at 60 cc., under the outlet, and quickly remove the cork, immediately starting the stop watch. When the oil in the flask reaches the 60 cc. mark, stop the watch. The time, in seconds, required to fill the flask to the 60 cc. mark represents the viscosity of the liquid. A fuller description of the apparatus and the details of manipulation are given in the U. S. Bureau of Mines, Technical Paper, 323 A.

Table for Conversion of Saybolt or Engler Viscosity into Kinematic Viscosity

Column 1 = Viscosity, Saybolt Universal, sec.
Column 2 = Kinematic viscosity, poises divided by Gm. per cc.
Column 3 = Viscosity, Engler degrees.

1	2	3	1	2	3	1	2	3	1	2	3

CHAPTER XCII

REAGENTS AND TEST SOLUTIONS

Reagents, Test Solutions and Volumetric Solutions

Reagents are substances used in chemical testing or in microscopic examinations.

Test Solutions, abbreviated "T. S.," are solutions of prescribed strength of reagents in appropriate solvents for use in applying tests.

Indicators are reagents or test solutions employed for the purpose of determining the completion of reactions.

Volumetric Solutions are solutions of reagents of accurately determined strength. The strength is usually related to the molecular weight. These solutions are primarily intended for quantitative estimations.

Some official substances are satisfactory for use as reagents or test solutions if they comply with the tests for purity given in the monographs of the Pharmacopœia. Space is conserved by simply referring to these where such is the case.

When a substance is not official or when a greater degree of purity is required than is provided for in the monograph, the substance will be found in the following list, with such description and tests as will insure its suitability for the purpose intended.

Reagents, test solutions, volumetric solutions, and indicators should be preserved in bottles or other containers made of glass of a minimum solubility and low alkalinity, and approximately free from lead or arsenic. The bottles must be capable of being tightly closed with appropriate stoppers.

When ground glass stoppers are directed for bottles and apparatus which are to contain substances capable of attacking such surfaces, the ground glass surfaces are to be coated with a thin film of petrolatum. Certain reagents and their solutions are affected by light. In such cases, the direction to keep the substances in amber-colored glass bottles should be carefully observed.

Water, wherever mentioned in carrying out tests or as a solvent in preparing test solutions, etc., is always meant to be distilled water.

The chemical formulas when definitely known, immediately follow the titles of the reagents. This is for convenience and is not to be interpreted as meaning that the reagents are of absolute purity and strength.

Amounts of Substances to be Used in Applying Tests—When not otherwise stated, it is to be understood that a volume of 10 cc. of an aqueous solution of the designated strength is to be used for a test.

Reagents

Acetic Acid, $CH_3.COOH$—Use *Acidum Aceticum.*

Acetic Acid, Diluted—Use *Acidum Aceticum Dilutum.*

Acetic Acid, Glacial, $CH_3.COOH$—Use *Acidum Aceticum Glaciale*, page 13.

Acetic Anhydride, $(CH_3CO)_2O$—A colorless liquid having a pungent odor. Boiling point, about 137° C. Specific gravity, about 1.075 at 25° C. Non-volatile residue at 110° C. not over 0.005 per cent. An aqueous solution (1 in 50) gives no reaction for *chloride.* One Gm., when dissolved in 50 cc. of distilled water and allowed to stand for one hour in a stoppered flask, requires not less than 19.3 cc. of normal sodium hydroxide for neutralization, using phenolphthalein T.S. as indicator, corresponding to at least 90 per cent of $(CH_3CO)_2O$.

Preserve in glass-stoppered bottles in a cool, dry place. The stoppers should be sealed with paraffin.

Acetone CH_3COCH_3—Use *Acetonum.*

Alcohol, C_2H_5OH—Use *Alcohol.*

Alcohol, Dehydrated (*Absolute Alcohol*), C_2H_5OH—Use the official *Alcohol Dehydratum.*

Alcohol, Neutralized—To a suitable quantity of alcohol, add 2 or 3 drops of phenolphthalein T.S. and just sufficient fiftieth-normal or tenth-normal sodium hydroxide to produce a slight pink color. Neutralized alcohol should be prepared immediately before using.

Aluminum Metallic, Al—Aluminum in the form of wire.

Ammonium Carbonate, $NH_4HCO_3.NH_4NH_2CO_2$—In addition to the description and tests for *Ammonii Carbonas,* page 655, it must conform to the following tests: Residue upon incineration not over 0.01 per cent. An aqueous solution (1 in 10) gives no reaction for *chloride, phosphate, sulphate, thiocyanate, or heavy metals.*

Ammonium Chloride, NH_4Cl—In addition to the description and tests for *Ammonii Chloridum,* page 656, it must conform to the following tests: Residue upon incineration not over 0.03 per cent. An aqueous solution (1 in 10) gives no reaction for *phosphate, sulphate, thiocyanate, or heavy metals.* Ammonium chloride employed in the test for lead under citric and tartaric acids and their salts, must also comply with the following special test. Dissolve 3 Gm. in 10 cc. of distilled water, acidified with 1 drop of reagent hydrochloric acid, in a test tube having an internal diameter of about 20 mm., add 10 cc. of clear, colorless hydrogen sulphide T.S., and mix well. The liquid must show no color when viewed downward against a white background.

Ammonium Nitrate, NH_4NO_3—Colorless crystals, or white granules, very soluble in water, slightly soluble in alcohol. Residue upon incineration not over 0.03 per cent. An aqueous solution (1 in 10) gives no reaction for *chloride, phosphate, sulphate, thiocyanate, or heavy metals.* An aqueous solution (1 in 20) gives no reaction for *nitrite* when tested as follows: To a solution of 1 Gm. of ammonium nitrate in 20 cc. of distilled water add 2 cc. of diluted sulphuric acid and 1 cc. of metaphenylenediamine hydrochloride T.S.: no yellow or yellowish-brown color develops.

Ammonium Oxalate, $(NH_4)_2C_2O_4.H_2O$—Colorless crystals, soluble in water. Residue, upon incineration, not over 0.03 per cent. An aqueous solution (1 in 25) gives no reaction for *chloride, phosphate, sulphate, or heavy metals.*

Ammonium Sulphate, $(NH_4)_2SO_4$—Colorless crystals or white granules, very soluble in water. Residue upon incineration not over 0.05 per cent. An aqueous solution (1 in 10) gives no reaction for *chloride, phosphate, thiocyanate, or heavy metals.*

Ammonium Vanadate (*Ammonium Metavanadate*), NH_4VO_3—A white crystalline powder, slightly soluble in water. Easily decomposed upon heating either dry or in solution.

Amyl Alcohol, $C_5H_{11}OH$—Colorless, oily liquid. Boiling point, 128° to 132° C. Specific gravity, about 0.812 at 25° C. Miscible with alcohol, ether, chloroform, carbon disulphide, petroleum benzin, benzene, and fixed or volatile oils. Slightly soluble in water. Non-volatile residue at 100° C., not over 0.005 per cent.

Aniline, $C_6H_5NH_2$—A colorless or nearly colorless, strongly refractive, oily liquid. Boiling point, 182° to 184° C. Specific gravity, about 1.020 at 25° C. Soluble in water; miscible with alcohol, ether, and fixed or volatile oils. Five cc. of aniline dissolved in 10 cc. of hydrochloric acid, produces a clear solution. Upon diluting this solution with 15 cc. of distilled water and cooling to 15° C., the liquid does not become more than slightly cloudy.

Preserve in amber-colored bottles. Upon keeping, it often assumes a yellow or brown color, and should then be distilled before using.

Aniline Sulphate, $(C_6H_5NH_2)_2H_2SO_4$—White or nearly white crystals, very soluble in water, slightly soluble in alcohol.

Arsenic Trioxide, As_2O_3—Use *Arseni Trioxidum.*

Asbestos—The silky, well-matted variety of long-fiber asbestos. When moistened and rolled between the thumb and finger, it forms a compact mass. For use as a filtering medium for the Gooch crucible, boil the asbestos for one hour with diluted hydrochloric acid, and wash it with boiling distilled water until free from all acid.

Barium Chloride, $BaCl_2.2H_2O$—Colorless crystals, freely soluble in water, slightly soluble in alcohol and in concentrated hydrochloric acid. An aqueous solution (1 in 20) is neutral and gives no reaction for *nitrate, chlorate, or heavy metals.* Dissolve 2 Gm. of barium chloride in 100 cc. of distilled water, add a few drops of hydrochloric acid, heat to boiling, then add 20 cc. of diluted sulphuric acid, and set aside for at least twelve hours. Filter, evaporate the filtrate, and ignite. The weight of the residue does not exceed 0.002 Gm. (*other fixed bases*). Shake 1 Gm. of finely powdered barium chloride with 20 cc. of dehydrated alcohol during five minutes, filter, evaporate the filtrate, and ignite. The weight of the residue does not exceed 0.002 Gm. (*strontium and calcium*).

Barium Hydroxide, $Ba(OH)_2.8H_2O$—Colorless crystals, soluble in water, very soluble in boiling water. An aqueous solution (1 in 20) gives no reaction for *chloride or heavy metals.* Dissolve 2 Gm. of barium hydroxide in 100 cc. of distilled water, add 5 cc. of hydrochloric acid, heat to boiling, then add 15 cc. of diluted sulphuric acid, and set aside for at least twelve hours. Filter, evaporate the filtrate, and ignite. The weight of the residue does not exceed 0.003 Gm. (*other fixed bases*).

Assay—One Gm. dissolved in distilled water, and titrated with normal hydrochloric acid, using methyl orange T.S. as indicator, shows not less than 99 per cent of $Ba(OH)_2.8H_2O$.

Preserve in tightly-stoppered containers to prevent access of carbon dioxide.

Barium Nitrate, $Ba(NO_3)_2$—Colorless crystals, soluble in water, freely soluble in boiling water. An aqueous solution (1 in 20) gives no reaction for *heavy metals* and meets the requirements of the test for *other fixed bases* under *barium chloride.* Converted into chloride by twice evaporating to dryness with hydrochloric acid, it meets the requirements of the tests for *strontium and calcium* under *barium chloride.*

Benzene (*Benzol*), C_6H_6—A colorless, transparent, liquid. Boiling point, 79° to 81° C. Congealing point, about 5° C. Specific gravity, about 0.876 at 25° C. Insoluble in water, miscible with alcohol, ether, and with fixed or volatile oils. When equal volumes of benzene and sulphuric acid are shaken together in a glass cylinder during fifteen minutes, the acid upon separation is not colored. Add a few mgm. of isatin, shake well, and allow to stand for thirty minutes. The acid does not acquire a blue or green color (*thiophene*). Non-volatile residue at 100° C., not over 0.01 per cent.

Benzidine (*Paradiaminodiphenyl*), $(C_6H_4NH_2)_2$—A white or slightly reddish crystalline powder. Sparingly soluble in cold water, slightly soluble in boiling water, alcohol, and ether. Melting point, about 128° C. A solution (1 in 50) in 2 per cent hydrochloric acid gives no reaction for *sulphate.* Residue upon incineration not over 0.05 per cent.

Benzin, Petroleum—Use *Benzinum Purificatum.*

Betanaphthol, $C_{10}H_7OH$—Use *Betanaphthol.*

Bromine, Br—A dark reddish-brown fuming, corrosive volatile liquid containing not less than 99 per cent of Br and not more than 1 per cent of Cl. Specific gravity, about 3.1 at 25° C. Soluble in about 30 parts of water, soluble in alcohol and in ether (with gradual decomposition of the solvents). Dissolve about 1 cc. of bromine in 50 cc. of sodium hydroxide T.S. and allow to stand for six hours: the solution remains clear (*organic bromine compounds*). Agitate 10 cc. of a saturated aqueous solution of bromine with 1 Gm. of reduced iron until the solution is nearly colorless. Filter and add 1 cc. of starch T.S. and 1 cc. of ferric chloride T.S.: no blue color develops (*iodine*). Non-volatile residue at 100° C., not over 0.01 per cent.

Assay—Dissolve 10 Gm. of potassium iodide in 25 cc. of distilled water, introduce the solution into a 100 cc. measuring flask, stopper, and determine accurately the weight of the flask and its contents. Add about 1 Gm. of bromine to the contents of the flask, determine its exact weight, then fill the flask to the mark with distilled water, and titrate 25 cc. of this solution with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each Gm. of bromine (containing not more than 1 per cent of chlorine) corresponds to not more than 126.7 cc. of tenth-normal sodium thiosulphate. Preserve in glass-stoppered bottles, in a cool place, the bottles being enclosed in larger vessels with the space between filled with some substance, capable of absorbing bromine.

Cadmium and Potassium Iodide—A mixture of equal weights of cadmium iodide and potassium iodide. An aqueous solution (1 in 20) shows no *free iodine.*

Cadmium Chloride, $CdCl_2.2H_2O$—Small, colorless crystals, efflorescent in dry air. Very soluble in water, soluble in alcohol.

Cadmium Iodide, CdI_2—Colorless crystals, becoming yellow upon exposure to light and air. Very soluble in water and in alcohol, sparingly soluble in ether and acetone.

Calcium Carbonate, $CaCO_3$—Use *Calcii Carbonas Præcipitatus.*

Calcium Chloride, $CaCl_2.2H_2O$—In addition to the description and tests for *Calcii Chloridum,* page 676, it must conform to the following tests: One Gm. dissolves completely in 10 cc. of alcohol. An aqueous solution (1 in 20) is neutral to litmus paper, does not respond to the test for *heavy metals,* and yields no precipitate with an equal volume of calcium sulphate T.S. (*barium*). One Gm. of calcium chloride shows no *ammonia* when warmed with sodium hydroxide, and 0.5 Gm. meets the requirements of the test for *arsenic.* Precipitate the calcium from 1 Gm. of the salt dissolved in 50 cc. of distilled water by ammonium oxalate T.S., evaporate and ignite the filtrate: the residue does not exceed 0.3 per cent (*alkali and magnesium salts*).

Calcium Chloride, Fused, $CaCl_2$—Deliquescent lumps or granules. It complies with the test for identity and purity under *Calcii Chloridum,* page 676, and when assayed by the method given under that substance shows not less than 98 per cent of $CaCl_2$.

Calcium Sulphate, $CaSO_4.2H_2O$—Transparent crystals, crystalline masses or a white powder. Slightly soluble in water.

Canada Turpentine—A liquid oleoresin from *Abies balsamea* (Linné) Miller (Fam. *Pinaceæ*). A pale yellow or greenish, viscid, transparent liquid. Completely soluble in ether, chloroform, and benzene. When exposed to the air, Canada turpentine gradually dries and remains transparent. Canada turpentine solidifies when mixed with 20 per cent of its weight of magnesium oxide, previously moistened with water.

Carbon Disulphide, CS_2—A clear, colorless, very volatile, inflammable liquid. Boiling point, about 46° C. Specific gravity, about 1.26 at 25° C. Slightly soluble in water, very soluble in alcohol, ether, chloroform and fixed or volatile oils. Carbon disulphide does not affect the color of blue litmus paper moistened with water (*sulphur dioxide*). Agitate 10 cc. of carbon disulphide with 0.5 Gm. of lead carbonate: the latter should not acquire a brown color (*foreign sulphur compounds*). Non-volatile residue at 100° C., not over 0.004 per cent.

Carbon Tetrachloride, CCl_4—Use *Carbon Tetrachloridum.*

Casein—A white or slightly yellow, odorless, granular powder. Insoluble in water and other neutral solvents, but readily dissolved by ammonia T.S. and by solutions of alkali hydroxides, forming a cloudy solution. Ash: not more than 1 per cent. Loss on drying at 100° C., not more than 10 per cent. Shake 1 Gm. of casein with 20 cc. of distilled water for ten minutes and filter: the filtrate is not alkaline to litmus paper, and on evaporating to dryness and drying at 100° C., the residue does not exceed 0.1 per cent (*soluble substances*). Dissolve 1 Gm. of casein in 10 cc. of distilled water, with 5 cc. of alcoholic ammonia T.S., and shake out with two successive portions of 20 cc. each of purified petroleum benzin. Evaporate the benzin extract at a low temperature and dry at 70° C. The weight of the residue does not exceed 0.5 per cent (*fats*). Anhydrous casein contains from 15.2 to 16 per cent of nitrogen, using the Kjeldahl method.

Charcoal—Use *Carbo Ligni.*

Chloral Hydrate, $CCl_3CHO.H_2O$—Use *Chloralis Hydras.*

Chlorinated Lime—Use *Calx Chlorinata.*

Chloroform, $CHCl_3$—Use *Chloroformum.*

Chromium Trioxide, CrO_3—Use *Chromii Trioxidum.*

Cobaltous Chloride, (*Cobalt Chloride*) $CoCl_2.6H_2O$—Red crystals or a red, crystalline powder. Very soluble in water and in alcohol, soluble in acetone and in glycerin. Dissolve 2 Gm. of cobaltous chloride in 100 cc. of distilled water. Completely precipitate the cobalt by the addition of an excess of ammonia T.S., followed by ammonium sulphide T.S., and filter. The filtrate, after evaporation and ignition, leaves not more than 0.008 Gm. of residue (*salts of alkalies and alkali earths*). Dissolve 1 Gm. of cobaltous chloride in 20 cc. of distilled water, add 3 Gm. of sodium cyanide, and boil until the solution acquires a yellow color. Filter, add 1 cc. of bromine, and sufficient sodium hydroxide T.S. to render strongly alkaline: no brown color develops (*nickel*). A solution of cobaltous chloride (1 in 20) strongly acidulated with hydrochloric acid, yields no dark precipitate with hydrogen sulphide (*lead or copper*).

Copper, Cu—Copper in the form of wire, foil, turnings, filings, or granules. It should give no reaction for *antimony, lead, silver, or tin.* It should contain not more than 0.03 per cent of *iron* and not more than 0.0001 per cent of *arsenic.*

Cupric Acetate, $Cu(C_2H_3O_2)_2.H_2O$—Bluish-green crystals, or powder, having an acetous odor. Soluble in water, slightly soluble in alcohol. It should contain not more than 0.01 per cent of *sulphate or chloride.* Dissolve 1 Gm. of cupric acetate in 100 cc. of distilled water, add 1 cc. of hydrochloric acid, completely precipitate the copper with hydrogen sulphide, filter, evaporate the filtrate to dryness, and gently ignite: the residue does not exceed 0.5 per cent.

Cupric Sulphate, $CuSO_4.5H_2O$—Use *Cupri Sulphas.*

Cupric Sulphate, Anhydrous, $CuSO_4$—A white or grayish-white powder, free from a blue tinge. Upon adding a small quantity of water, it becomes blue. It is soluble in

water and responds to the reactions characteristic of copper and sulphates. An aqueous solution (1 in 50) yields no immediate reaction for *chloride*. Precipitate the copper from a solution of 2 Gm. in 100 cc. of distilled water, acidulated with 2 cc. of hydrochloric acid, with hydrogen sulphide, and filter. Evaporate the filtrate to dryness and gently ignite: the residue does not exceed 0.1 per cent.

Curare—The composition of curare is not definitely known, and different specimens vary, depending upon the special variety of plant used in its manufacture. The most important source of curare is the bark of several varieties of *Strychnos*, the species most commonly employed being *S. Castelnæi*, Wedd., *S. Toxifera* Benth., *or S. Crevauxii* G. Planch. (Fam. *Loganiaceæ*). Commercial curare is a brownish or black, shining resinoid mass. About 75 per cent is soluble in cold water and it is almost completely soluble in diluted alcohol.

Dextrose, $C_6H_{12}O_6.H_2O$—Use *Dextrosum*.

Dichloramine, $C_7H_7O_2NSCl_2$—Use *Dichloramina*.

Diphenylamine, $(C_6H_5)_2NH$—Grayish-white or colorless crystals. Melting point, about 54° C. Slightly soluble in water and in alcohol. A solution of 0.2 Gm. in 20 cc. of sulphuric acid, is colorless (*nitrates*). No violet color results when 1 Gm. of powdered diphenylamine is added to 20 cc. of a saturated aqueous solution of chlorinated lime (*aniline*).

Epinephrine, $C_9H_{13}O_3N$—Use *Epinephrina*.

Ether, Dehydrated, $(C_2H_5)_2O$—It conforms to the description and tests for *aldehyde and peroxide*, page 917, and to the following: Specific gravity, not over 0.711 at 25° C. Boiling point, from 34° to 36° C. To 10 cc. of ether, contained in a dry, clean, glass cylinder, add 0.1 Gm. of rosaniline acetate: no coloration results (*water or alcohol*). Non-volatile residue at 100° C., not more than 0.002 per cent.

Ethyl Acetate, $CH_3COOC_2H_5$—A transparent, colorless, inflammable liquid. Soluble in water, miscible with alcohol, ether, and fixed or volatile oils. Boiling point, 75° to 77° C. Specific gravity: 0.893 to 0.898 at 25° C. Ethyl acetate does not redden moistened blue litmus paper. Evaporate 5 cc. of ethyl acetate from clean, odorless, unsized paper. The final odor is not different in character from that observed at the beginning of the test. Superimpose 5 cc. of ethyl acetate upon 5 cc. of sulphuric acid: no dark coloration is produced at the zone of contact (*readily carbonizable substances*). Non-volatile residue at 100° C., not more than 0.005 per cent.

Ferric Ammonium Sulphate, $FeNH_4(SO_4)_2.12H_2O$—Pale violet crystals. Efflorescent on exposure to air. Very soluble in water, insoluble in alcohol. An aqueous solution (1 in 20) gives no reaction for *chloride or ferrous salts*.

Ferric Chloride, $FeCl_3.6H_2O$—Use *Ferri Chloridum*.

Ferrous Sulphate, $FeSO_4.7H_2O$—Use *Ferri Sulphas*.

Ferrous Sulphide, FeS—Dark gray or grayish-black lumps, fragments, sticks, granules, or globules. It is insoluble in water but is dissolved by diluted sulphuric or diluted hydrochloric acid with copious evolution of hydrogen sulphide.

Filter Paper, Quantitative—For the Mercuric Bromide Test Paper of the Arsenic Test, use Schleicher and Schüll's No. 589 (Blue Ribbon), or Swedish O. filter paper, or other makes of like surface, quality and ash (see Arsenic Test.

Fluorescein (*Resorcinolphthalein*), $C_{20}H_{12}O_5$—A yellowish-red to dark red powder. Sparingly soluble in water and in ether, soluble in alcohol. Fluorescein dissolves in solutions of the alkali hydroxides or carbonates, forming a solution which has a bright green fluorescence. Ash, not over 0.25 per cent. Agitate about 1 Gm. of

fluorescein with 20 cc. of distilled water and filter. One drop of tenth-normal sodium hydroxide imparts to 10 cc. of the filtrate a bright green fluorescence. The addition of a drop of ferric chloride T.S. to the remaining portion of the filtrate does not produce a bluish coloration (*resorcinol or other phenolic compounds*).

Fuchsin, Basic (*Basic Fuchsin, Rosaniline, Rosaniline Acetate, Rosaniline Hydrochloride*)—Crystals or crystalline fragments with a glossy, greenish-bronze luster. Soluble in water, alcohol, and amyl alcohol. An aqueous solution (1 in 500) yields a red precipitate upon the addition of tannic acid T.S. To 10 cc. of an aqueous solution (1 in 500), add 10 cc. of ammonia T.S. and 0.5 Gm. of zinc dust, and agitate. Decolorization of the solution results. Place a few drops of this decolorized solution upon filter paper, then place near by, on the paper, a few drops of hydrochloric acid. The zone of contact assumes a red color. Ash: not over 0.25 per cent.

Gallic Acid, $HC_7H_5O_5.H_2O$—White or nearly white crystals. A cold, saturated aqueous solution of gallic acid neither colors nor precipitates solutions of pure ferrous salts, and does not produce a precipitate with gelatin T.S. (*tannic acid*).

Gelatin—Use *Gelatinum*.

Glass Wool—Fine threads of glass. Glass wool should yield not more than 0.5 per cent of soluble matter when boiled for one-half hour with diluted hydrochloric acid. Boil 1 Gm. of glass wool for five minutes with a mixture of 25 cc. each of diluted nitric acid and distilled water, filter, evaporate the filtrate to dryness, treat the residue with 10 cc. of distilled water, and again filter. This latter filtrate is not colored by the addition of an equal volume of hydrogen sulphide T.S. (*lead*).

Gold Chloride (*Chlorauric Acid*), $HAuCl_4.4H_2O$—Yellow, hygroscopic crystals. Very soluble in water, soluble in alcohol and in ether. An accurately weighed portion of about 0.1 Gm., when moistened with a slight excess of ammonium oxalate T.S., evaporated to dryness, ignited, and weighed, yields a residue of about 48 per cent of metallic gold. Heat the metallic gold thus obtained with diluted hydrochloric acid and filter. The filtrate gives no appreciable coloration with either hydrogen sulphide T.S. or ammonium sulphide T.S. (*other metals*).

Hematein, $C_{16}H_{12}O_6$—A product of the oxidation of hematoxylin. Reddish-brown crystalline plates of a greenish metallic luster. Sparingly soluble in water, alcohol and in ether, insoluble in chloroform. It is dissolved by ammonia T.S. with a brownish-violet color and by dilute solutions of caustic alkalies with a bright red color.

Hydrochloric Acid, HCl—Use *Acidum Hydrochloricum*.

Hydrochloric Acid, Concentrated, HCl—In addition to the description and identity tests for *Acidum Hydrochloricum*, page 553, it must conform to the following tests: Specific gravity, between 1.170 and 1.184 at 25° C., corresponding to from 35 to 38 per cent of HCl. Non-volatile residue, upon evaporation and ignition with a drop of sulphuric acid, not more than 0.002 per cent. Evaporate 100 cc. of concentrated hydrochloric acid to about 5 cc., dilute with 10 cc. of distilled water, and add 5 drops of barium chloride T.S.: no precipitate occurs within twelve hours (*sulphate*). Add 5 cc. of concentrated hydrochloric acid, diluted with 50 cc. of distilled water, to a solution of 1 drop of tenth-normal iodine in 50 cc. of distilled water to which a few drops of starch T.S. have been added: no decolorization occurs (*sulphur dioxide*). Dilute 10 cc. of the acid with about 100 cc. of distilled water at a temperature of about 50° C. and thoroughly saturate it with hydrogen sulphide: no dark coloration or precipitate forms either before or after rendering alkaline with ammonia T.S. and adding 5 drops of ammonium sulphide T.S. (*heavy metals*). Two cc. of concentrated

hydrochloric acid, diluted with 10 cc. of distilled water, when subjected to the arsenic test, page 1512, produces a stain not greater than that produced by the zinc alone.

Hydrochloric Acid, Diluted—Use *Acidum Hydrochloricum Dilutum.*

Hydrogen Sulphide, H_2S—A gas generated by treating ferrous sulphide with diluted sulphuric or hydrochloric acid.

Indicators—See page

Indigo Carmine, $C_{16}H_8O_2N_2(SO_3Na)_2$—Use *Sodii Indigotindisulphonas.*

Iodine, Purified, I—Prepared from *Iodum*, page 575, as follows: Powder a suitable quantity of iodine and place it in a porcelain dish. Heat it over a water bath for twenty minutes, stirring constantly with a glass rod to vaporize moisture and other impurities. Then transfer the iodine to a glass, porcelain, or wedgwood mortar and triturate with about 5 per cent of its weight of potassium iodide. Return the mixture to the dish, cover it with a glass funnel, and heat carefully on a sand bath to sublime the iodine. When the operation is completed, detach the sublimed iodine, powder it, and dry it over calcium chloride in a desiccator for twenty-four hours: the ash from 2 Gm. is negligible.

Preserve in well-closed, glass-stoppered bottles, in a cool place.

Iron, Fe—Bright, clean iron in the form of wire, sheet, filings, or powder. In the test for copper, use bright pieces of sheet iron or steel knitting needles.

Preserve iron in well-closed glass containers to protect it from moist air, acid fumes, etc.

Isatin, $C_8H_5NO_2$—Small yellowish-red crystals; slightly soluble in water, soluble in alcohol, and in ether. Melting point about 200° C. Aqueous, alcoholic or ethereal solutions of isatin are reddish-brown in color.

When isatin is dissolved in a solution of an alkali hydroxide, it yields a violet colored solution which upon heating or upon long standing becomes yellow.

Kerosene—A mixture of hydrocarbons, chiefly of the methane and naphthene series. It is a clear, colorless or only slightly colored liquid, having a characteristic but not disagreeable odor. Specific gravity about 0.80 at 25° C. Boils between 180° and 300° C. Prepare purified kerosene by shaking a convenient volume of kerosene twice with about one-tenth its volume of 15 per cent sodium hydroxide solution, then wash with distilled water until free from alkali.

Lead Acetate, $Pb(C_2H_3O_2)_2.3H_2O$—Use *Plumbi Acetas.*

Lead Carbonate, $(PbCO_3)_2.Pb(OH)_2$—A white, heavy powder. Insoluble in water and in alcohol. It is dissolved by acetic or diluted nitric acid with effervescence, the resulting solutions responding to the identity tests for lead.

Lead Monoxide, PbO—Use *Plumbi Monoxidum.*

Lead Nitrate, $Pb(NO_3)_2$—Colorless or white crystals or a white crystalline powder. Very soluble in water, almost insoluble in alcohol. Lead nitrate responds to the identity tests for lead, page 737, and nitrates, page 551, and meets the requirements of the tests for *foreign metals* under *Plumbi Acetas.*

Lead Peroxide (*Lead Dioxide*), PbO_2—A dark brown powder containing not less than 90 per cent of PbO_2. Insoluble in water and in alcohol. It is unaffected by nitric acid, but is decomposed by hydrochloric acid with the evolution of chlorine, and by hot sulphuric acid with the evolution of oxygen. It is dissolved by concentrated solutions of alkali hydroxides. Boil 2 Gm. of lead peroxide with 50 cc. of distilled water for fifteen minutes, filter, evaporate the filtrate to dryness and ignite. The residue does not exceed 0.5 per cent (*soluble salts*).

Assay—Dissolve about 0.5 Gm. of finely powdered lead peroxide, previously dried to constant weight at 100° C. and accurately weighed, in a solution made by mixing 1.5 Gm. of potassium iodide, 12 Gm. of sodium acetate, 8 cc. of glacial acetic acid, and 8 cc. of distilled water. Clear the solution if necessary by the further addition of sodium acetate, and then determine the liberated iodine by titration with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01195 Gm. of PbO_2.

Lime, Freshly Slaked, $Ca(OH)_2$—To prepare freshly slaked lime, drop upon a convenient quantity of lime, page 671, one-third of its weight of water, cover, and allow it to stand until it has been converted to a pulverulent mass and is cool. Freshly slaked lime, after drying and igniting, yields not more than 0.1 per cent of residue insoluble in hydrochloric acid and should show practically no effervescence when dissolved.

Magnesium Chloride, $MgCl_2.6H_2O$—White, deliquescent crystals, very soluble in water. An aqueous solution is neutral to litmus paper. Two Gm. of magnesium chloride should completely dissolve in 10 cc. of 85 per cent alcohol. Magnesium chloride also complies with the tests for *barium, calcium, heavy metals, and sulphate,* under reagent sodium chloride.

Magnesium Oxide, MgO—Use *Magnesii Oxidum.*

Magnesium Sulphate, $MgSO_4.7H_2O$—Use *Magnesii Sulphas.*

Manganese Dioxide, MnO_2—A fine heavy black powder, containing not less than 85 per cent of MnO_2. It is insoluble in water, but is dissolved by hydrochloric acid with the evolution of chlorine.

Assay—Dissolve about 0.2 Gm. of manganese dioxide, accurately weighed, in a mixture of 50 cc. of tenth-normal oxalic acid and 3 cc. of sulphuric acid, heat to about 80° C., and titrate the excess of oxalic acid with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid represents 0.0043465 Gm. of MnO_2.

Manganese Sulphate, $MnSO_4.4H_2O$ or $MnSO_4.5H_2O$—Pink crystals. Very soluble in water, insoluble in alcohol. An aqueous solution (1 in 50) gives no reaction for *chloride or iron.* Dissolve 1 Gm. of manganese sulphate in 50 cc. of distilled water, add 10 cc. of ammonium chloride T.S., heat to boiling, and precipitate the manganese with a slight excess of ammonium sulphide T.S. Continue the heating until the precipitate assumes a greenish color, then filter, evaporate the filtrate to dryness, and ignite: not more than 0.5 per cent of residue remains (*salts of foreign metals*).

Mercuric Bromide, $HgBr_2$—White needles, prisms, lustrous scales, or a granular, crystalline powder. Slightly soluble in cold water, soluble in boiling water and in alcohol. Mercuric bromide should be completely soluble in hot water. Residue upon incineration, not more than 0.05 per cent.

Mercuric Chloride, $HgCl_2$—Use *Hydrargyri Chloridum Corrosivum.*

Mercuric Oxide, Red, HgO—An orange-red, crystalline powder. Insoluble in water but dissolved by dilute nitric or dilute hydrochloric acid. A solution (1 in 50) in diluted nitric acid gives no reaction for *chloride or sulphate.* One Gm. mixed with 10 cc. of diluted sulphuric acid should give no reaction for nitrate with ferrous sulphate. Residue upon incineration, not more than 0.2 per cent. When dried to constant weight at 100 ° C. and assayed electrolytically or by titration with tenth-normal potassium thiocyanate, it should show not less than 99.5 per cent of HgO.

Mercurous Chloride, Mild, HgCl—Use *Hydrargyri Chloridum Mite.*

Mercury, Hg—Use *Hydrargyrum.*

Metaphenylenediamine Hydrochloride, $C_6H_4(NH_2)_2.2HCl$—A white, or slightly

reddish-white, crystalline powder, easily soluble in water. An aqueous solution (1 in 200) should be colorless.

Molybdic Acid—A white or yellowish-white powder of somewhat variable composition, containing, when assayed by the lead molybdate method, not less than 83 per cent of MoO_3. It is insoluble in water, soluble in solutions of alkali hydroxides. No insoluble residue should remain when 1 Gm. of molybdic acid is dissolved in 10 cc. of ammonia T.S. The addition of 10 cc. of hydrogen sulphide T.S. produces a greenish-yellow color but no brownish-yellow color or precipitate (*heavy metals*). Dissolve 10 Gm. of molybdic acid in 25 cc. of ammonia T.S., pour this solution gradually and with constant stirring into a mixture of 75 cc. of nitric acid and 75 cc. of distilled water, and set the solution aside for at least twelve hours at 40° C.: no yellow precipitate should appear (*phosphate*).

Naphthylamine (Alpha) Hydrochloride, $C_{10}H_7NH_2.HCl$—A white, crystalline powder which turns bluish upon exposure to light and air. Insoluble in water, soluble in alcohol and in ether. An aqueous solution (1 in 100) in diluted acetic acid gives a violet color with 5 drops of ferric chloride T.S. An aqueous solution (1 in 40) in diluted acetic acid should be colorless and not more than slightly opalescent from undissolved matter. Non-volatile residue upon incineration, not more than 0.05 per cent.

Naphthylamine (Beta) Acetate, $C_{10}H_7NH_2.C_2H_4O_2$—White to yellowish-white, crystalline scales or flakes. Slightly soluble in water, soluble in alcohol. An aqueous solution (1 in 100) does not give a violet color with 5 drops of ferric chloride T.S. (*alpha naphthylamine*).

Nitric Acid, HNO_3—Use *Acidum Nitricum*.

Nitric Acid, Diluted—Use a 10 per cent aqueous solution of HNO_3.

Nitric Acid, Fuming—A yellowish-red to brownish-red fuming liquid. Specific gravity, about 1.50 at 25° C. It conforms to the tests for purity under *Acidum Nitricum*, page 557, omitting the assay.

Preserve carefully in glass-stoppered bottles, in a cool place.

Oil of Cedar Wood—For clearing microscopic sections, a selected commercial distilled oil from the wood of the red cedar, *Juniperus virginiana*, Linné (Fam. *Pinaceæ*), should be used. Refractive index, about 1.504 at 20° C. For use with homogeneous immersion lenses, a specially prepared oil is required, having a refractive index of exactly 1.515 at 18° C.

Ouabain, $C_{30}H_{46}O_{12}.xH_2O$—Ouabain, crystallized from a mixture of alcohol and ether, contains approximately 12½ per cent of water, and requires a temperature of 130° C. for rapid and complete dehydration. The optical properties are as follows: In ordinary light—colorless rods. In parallel polarized light with crossed nicols extinction is parallel. The double refraction is strong. The sign of elongation is +

Refractive indices $\left(\begin{smallmatrix}20^\circ\\D\end{smallmatrix}\right)$: $\alpha = 1.540$ (crosswise), $\gamma = 1.580$ (lengthwise), both ± 0.002.

The specific rotation of anhydrous ouabain: $\left(\alpha\right)\begin{smallmatrix}20\\D\end{smallmatrix} = -31.3°$ to $-31.9°$.

Ouabain is stable at 130° C. Anhydrous ouabain, whether originally crystallized from alcohol and ether or from water at room temperature, begins to soften at about 180° C.

Oxalic Acid, $H_2C_2O_4.2H_2O$—Colorless, uneffloresced crystals. Soluble in water, very soluble in boiling water and in alcohol. Dissolve 2 Gm. of oxalic acid in 30 cc. of

distilled water, add 2 Gm. of sodium hydroxide, and treat with 1 cc. of Nessler's reagent: it shows no darker coloration than a blank test from which the oxalic acid has been omitted (*ammonium compounds*). An aqueous solution (1 in 20) gives no reaction for *chloride, sulphate, nitrate, or heavy metals*. Residue upon incineration, not over 0.05 per cent. Preserve in well-stoppered bottles.

Palladous Chloride, $PdCl_2$—A dark brown, hygroscopic powder, yielding a turbid solution with water, in consequence of the formation of a basic salt.

Phenol, C_6H_5OH—Use *Phenol*.

Phenylhydrazine, $C_6H_5.NH.NH_2$—A colorless or slightly yellowish, highly refractive liquid. Boiling point, about 242° C., congealing when cold to crystalline plates which melt at 19° C. Slightly soluble in water, soluble in alcohol and in ether. Its aqueous solution soon becomes dark from oxidation. Shake 2 cc. of phenylhydrazine with 20 cc. of 5 per cent acetic acid: a clear liquid results.

Phloroglucinol, $C_6H_3(OH)_3.2H_2O$—White or yellowish-white crystals or a crystalline powder. Slightly soluble in water, soluble in alcohol and in ether. When rapidly heated, it melts between 217° and 219° C. When slowly heated, it melts at a much lower temperature. Add 0.1 Gm. of phloroglucinol to 1 cc. of acetic anhydride and 1 cc. of sulphuric acid in a test tube, and heat in a bath of boiling water for ten minutes: no blue color develops (*diresorcinol*).

Phosphoric Acid, H_3PO_4—Use *Acidum Phosphoricum*.

Phosphotungstic Acid, approximately $P_2O_5.24WO_3.xH_2O$—White or yellowish-green crystals or a crystalline powder. Soluble in water and in alcohol. Slightly soluble in ether. To a solution of 1 Gm. of phosphotungstic acid in 10 cc. of distilled water, add 0.1 Gm. of sodium chloride and 3 drops of indigo carmine T.S., then cautiously add 10 cc. of sulphuric acid, and allow the liquid to stand for ten minutes: the blue color does not disappear (*nitrate*). An aqueous solution (1 in 10) gives no reaction for *ammonium salts*.

Picric Acid, $C_6H_2(OH)(NO_2)_3$—Use *Trinitrophenol*.

Platinic Chloride (*Chloroplatinic Acid*), $H_2PtCl_6.6H_2O$—A brownish-red, very hygroscopic, crystalline mass. Very soluble in water, soluble in alcohol and in ether. It dissolves completely in 10 parts of water or alcohol, forming yellow solutions. The residue, upon incineration in a porcelain crucible, is not less than 37.6 per cent. When this residue is treated with 50 times its weight of diluted nitric acid for fifteen minutes on a water bath, the acid solution, upon filtration, evaporation to dryness and incineration, yields a residue not exceeding 0.15 per cent of the platinic chloride taken.

Potassium and Sodium Tartrate, $KNaC_4H_4O_6.4H_2O$ — Use *Potassii et Sodii Tartras*, page 301.

Potassium Acetate, $KC_2H_3O_2$—Use *Potassii Acetas*.

Potassium Bicarbonate, $KHCO_3$—Use *Potassii Bicarbonas*.

Potassium Bisulphate, $KHSO_4$—Fused white, deliquescent masses or granules. Reaction acid. Freely soluble in water. It responds to the identity tests for potassium, page 596, and for sulphates, page 581.

Potassium Bitartrate, $KHC_4H_4O_6$—In addition to the tests described under *Potassii Bitartras*, page 602, it gives no reaction for *chloride, sulphate, calcium, ammonium compounds, or heavy metals*. Heat 5 Gm. of potassium bitartrate at 100° C. for thirty minutes: no loss of weight should result. Dissolve 5 Gm. of potassium bitartrate, accurately weighed, in 250 cc. of hot distilled water, heat to boiling, and titrate

with normal sodium hydroxide, phenolphthalein T.S. being used as indicator: it shows not less than 99.9 per cent and not more than 100 per cent of $KHC_4H_4O_6$.

Potassium Bromate, $KBrO_3$—White crystals or a granular powder. Soluble in water, slightly soluble in alcohol. An aqueous solution (1 in 20) is neutral and should not at once acquire a yellow color upon the addition of 3 drops of diluted sulphuric acid (*bromide*).

Assay—When dried to constant weight at 100° C. and assayed by titration with tenth-normal sodium thiosulphate, after adding potassium iodide and hydrochloric acid, it shows not less than 99.8 per cent of $KBrO_3$. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.002784 Gm. of $KBrO_3$.

Potassium Carbonate, $K_2CO_3.xH_2O$—Use *Potassii Carbonas.*

Potassium Carbonate, Anhydrous, K_2CO_3—White granules or powder, very hygroscopic. Very soluble in water with the evolution of heat. When heated to redness, it should not lose more than 1 per cent of its weight (*water*). It meets the requirements of the tests for identity and purity under *Potassii Carbonas*, making allowance for the difference in water content.

Potassium Chlorate, $KClO_3$—Use *Potassii Chloras.*

Potassium Chloride, KCl—Colorless crystals or a white, granular powder. It is odorless. Freely soluble in water, slightly soluble in alcohol. Its aqueous solution (1 in 10) is neutral to litmus paper, and imparts to a non-luminous flame not more than a slight transient yellow color (*sodium*). To a solution of 1 Gm. of the salt in 5 cc. of distilled water, add an equal volume of sulphuric acid and 1 drop of indigo T.S.: the blue color does not disappear (*nitrate*). Potassium chloride also complies with the tests for *barium, sulphate, magnesium, calcium, heavy metals, and ammonia* under *Reagent Sodium Chloride.*

Potassium Chromate, K_2CrO_4—Yellow crystals, very soluble in water, insoluble in alcohol. An aqueous solution (1 in 20) is not reddened by phenolphthalein T.S. An aqueous solution (1 in 20) gives no reaction for *aluminum or calcium.* Ten cc. portions of an aqueous solution (1 in 20), acidulated respectively with 5 cc. of nitric acid and 3 cc. of hydrochloric acid, give no reaction for *chloride or sulphate.*

Potassium Citrate, $K_3C_6H_5O_7.H_2O$—Use *Potassii Citras.*

Potassium Dichromate, $K_2Cr_2O_7$—Dark yellowish-red crystals or crystalline granules. Soluble in water. An aqueous solution (1 in 20) should give no reaction for *aluminum or calcium.* Twenty cc. portions of an aqueous solution (1 in 20), treated respectively with 5 cc. of nitric acid and 2 cc. of hydrochloric acid, should give no reaction for *chloride* and no reaction for *sulphate* within eighteen hours after adding 1 cc. of barium chloride T.S.

Assay—When dried to constant weight at 100° C. and assayed by titration with tenth-normal sodium thiosulphate, after adding potassium iodide, and diluted sulphuric acid, it shows not less than 99.9 per cent of $K_2Cr_2O_7$.

Potassium Ferricyanide, $K_3Fe(CN)_6$—Dark red crystals. Very soluble in water. An aqueous solution (1 in 20) gives no reaction for sulphate. An aqueous solution (1 in 50), to which 2 drops of ferric chloride T.S. have been added, forms a clear, brown solution free from any green or blue coloration (*ferrocyanide*).

Potassium Ferrocyanide, $K_4Fe(CN)_6.3H_2O$ —Yellow, transparent, soft crystals very soluble in water. An aqueous solution (1 in 20) is neutral to litmus paper and gives no reaction for *sulphate.*

Potassium Hydroxide, KOH—Use *Potassii Hydroxidum.*

Potassium Iodide, KI—Use *Potassii Iodidum.*

Potassium Nitrate, KNO_3—In addition to the description and tests given under *Potassii Nitras,* page 612, it should conform to the following tests: An aqueous solution (1 in 20) gives no reaction for *sulphate.* Gently ignite 1 Gm. of potassium nitrate and dissolve the residue in 10 cc. of distilled water: it gives no reaction for *chloride.*

Potassium Nitrite, KNO_2—White or nearly white, deliquescent sticks. It responds to the identity tests for potassium, page 596, and for nitrites, page 551.

Potassium Permanganate, $KMnO_4$—Use *Potassii Permanganas.*

Potassium Sulphate, K_2SO_4—Hard, colorless crystals or a white powder, soluble in water. An aqueous solution (1 in 20) is neutral to litmus paper, and gives no reaction for *heavy metals, chloride, iron, calcium, magnesium, ammonia, or nitrate.* An aqueous solution (1 in 30) meets the requirements of the test for *arsenic.*

Potassium Thiocyanate (*Potassium Sulphocyanate*), KSCN—Colorless, hygroscopic crystals. Very soluble in water, completely soluble in 8 parts of warm alcohol without coloration. An aqueous solution (1 in 20) gives no reaction for *sulphate, heavy metals, or ammonia.*

Pyrogallol, $C_6H_3(OH)_3$—Use *Pyrogallol.*

Resorcinol, $C_6H_4(OH)_2$—Use *Resorcinol.*

Salicylic Acid, $HC_7H_5O_3$—Use *Acidum Salicylicum.*

Selenous Acid, H_2SeO_3—Colorless crystals. Efflorescent in dry air and hygroscopic in moist air. Soluble in water and in alcohol.

Silver, Ag—Silver in foil or wire containing not more than 0.025 per cent of *foreign metals.*

Silver Nitrate, $AgNO_3$—Use *Argenti Nitras.*

Silver Sulphate, Ag_2SO_4—Small, white, lustrous crystals or a white powder. Slightly soluble in water and dissolved by nitric acid, or by ammonia T.S.

Preserve in amber-colored bottles.

Sodium Acetate, $NaC_2H_3O_2.3H_2O$—Use *Sodii Acetas.*

Sodium Acetate, Anhydrous, $NaC_2H_3O_2$—Made from sodium acetate by heating it carefully until all water of crystallization is driven off and a dry powder results. It contains not more than 3 per cent of *water.*

Sodium Bicarbonate, $NaHCO_3$—Use *Sodii Bicarbonas.*

Sodium Bisulphite (*Sodium Acid Sulphite*), $NaHSO_3$—White crystals or a white granular powder, having the odor of sulphur dioxide. Freely soluble in water, slightly soluble in alcohol. An aqueous solution (1 in 50), boiled with a slight excess of hydrochloric acid to expel sulphur dioxide, gives no reaction for *heavy metals* and 0.2 Gm., oxidized with nitric acid, meets the requirements of the test for *arsenic.*

Assay—Dissolve a weighed amount of sodium bisulphite in distilled water, add a measured excess of tenth-normal iodine, and titrate the excess of iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal iodine corresponds to 0.005204 Gm. of $NaHSO_3$. It shows not less than 90 per cent of $NaHSO_3$. Preserve in well-filled, well-stoppered bottles, in a cool place.

Sodium Bitartrate, $NaHC_4H_4O_6.H_2O$ — White crystals or crystalline powder. Soluble in cold water. An aqueous solution (1 in 10) is clear and colorless and gives no reaction for *sulphate or heavy metals.* An aqueous solution (1 in 40) gives no reaction for *chloride.*

Sodium Borate, $Na_2B_4O_7.10H_2O$—Use *Sodii Boras.*

Sodium Bromide, NaBr—Use *Sodii Bromidum.*

Sodium Carbonate, Anhydrous, Na_2CO_3—A white, hygroscopic powder, soluble in water. An aqueous solution (1 in 10) should be clear and colorless and gives no reaction for *sulphate, silicate, nitrate, phosphate, calcium, magnesium, iron, ammonia, heavy metals,* contains not more than 0.005 per cent of *chloride* and meets the requirements of the test for *arsenic.* Not more than traces of potassium should be shown by the flame test, using cobalt glass. Titrate about 1.5 Gm. of anhydrous sodium carbonate, accurately weighed, with normal sulphuric acid, methyl orange T.S. being used as indicator. It shows not less than 99 per cent of Na_2CO_3.

Sodium Carbonate, Monohydrated, $Na_2CO_3.H_2O$—Use *Sodii Carbonas Monohydratus.*

Sodium Chloride, NaCl—In addition to the requirements and the tests prescribed under *Sodii Chloridum,* it is required to conform to the following additional tests. An aqueous solution of sodium chloride (1 in 20) shows no turbidity or precipitation on the addition of dilute sulphuric acid (*barium*). To a solution of 3 Gm. of sodium chloride in 80 cc. of distilled water, add 1 cc. of concentrated hydrochloric acid (page 1534), heat to boiling, and add about 5 cc. of barium chloride T.S. No precipitation takes place within twenty-four hours (*sulphate*). To a solution of 3 Gm. of sodium chloride in about 10 cc. of distilled water, add 5 cc. of ammonia T.S., and 5 cc. of sodium phosphate T.S.: no precipitation takes place within twelve hours (*magnesium salts*). Dissolve 5 Gm. of the salt in 80 cc. of distilled water, heat the solution to boiling, and add 5 cc. of ammonium oxalate T.S.: no precipitate is produced within twelve hours (*calcium*); nor is this solution affected by the addition of sodium carbonate T.S.; nor is a freshly prepared solution of the same concentration affected by the addition of ammonium sulphide T.S. (*alkali earths and heavy metals*). To a solution of 1 Gm. of sodium chloride in 10 cc. of distilled water, add 5 cc. of sodium cobaltic nitrite T.S.: no precipitation occurs after twenty-four hours (*potassium*). The addition of Nessler's Reagent (page 1548) to a solution of 3 Gm. of sodium chloride produces no yellow coloration (*ammonium salts*).

Sodium Cyanide, NaCN—White, opaque, amorphous fragments, or a white, granular powder. Very soluble in water. An aqueous solution (1 in 10) gives no reaction for *ferrocyanides or thiocyanates.*

Assay—Dissolve about 0.45 Gm. of sodium cyanide, accurately weighed, in 25 cc. of distilled water, add 4 cc. of ammonia T.S., 3 drops of potassium iodide T.S., and titrate with tenth-normal silver nitrate to the production of a permanent turbidity: it shows not less than 95 per cent of NaCN. Each cc. of tenth-normal silver nitrate represents 0.009802 Gm. of NaCN.

Sodium Hydroxide, NaOH—Use *Sodii Hydroxidum.*

Sodium Nitrite, $NaNO_2$—Use *Sodii Nitris.*

Sodium Nitroprusside (*Sodium Nitroferricyanide*), $Na_2Fe(NO)(CN)_5.2H_2O$—Transparent, dark-red crystals, very soluble in water. An aqueous solution (1 in 50) gives no reaction for *sulphate.*

Sodium Oxalate, $Na_2C_2O_4$—A white, crystalline powder, slightly soluble in water. The loss on drying at 105° C. does not exceed 0.01 per cent. The residue insoluble in water does not exceed 0.01 per cent. *Sulphate,* not over 0.001 per cent. *Chloride,* not over 0.002 per cent. *Iron,* not over 0.002 per cent. *Sodium bicarbonate,* not over 0.03 per cent. *Sodium binoxalate,* not over 0.02 per cent.

Sodium Phosphate, $Na_2HPO_4.12H_2O$—Use *Sodii Phosphas.*

Sodium Sulphide, $Na_2S.9H_2O$—Clear, colorless, deliquescent crystals. Very

soluble in water. An aqueous solution (1 in 10) is alkaline to litmus paper and has an odor of hydrogen sulphide.

Assay—Transfer about 0.3 Gm. of sodium sulphide, accurately weighed, to a flask containing 40 cc. of tenth-normal iodine. Allow it to stand until the sulphide is completely decomposed, add 2 cc. of hydrochloric acid and titrate with tenth-normal sodium thiosulphate. It shows not less than 95 per cent of $Na_2S.9H_2O$. Each cc. of tenth-normal iodine represents 0.01201 Gm. of $Na_2S.9H_2O$.

Sodium Sulphite, Exsiccated, Na_2SO_3—A white powder, freely soluble in water, slightly soluble in alcohol. An aqueous solution (1 in 50), boiled with a slight excess of hydrochloric acid to expel sulphur dioxide, gives no reaction for *heavy metals.*

Assay—Dissolve 0.5 Gm. of exsiccated sodium sulphite in sufficient freshly boiled distilled water to make 100 cc. Run this solution gradually from a burette into a mixture of 30 cc. of tenth-normal iodine and 5 cc. of hydrochloric acid, until complete decolorization results, using starch T.S. as indicator. It shows not less than 85 per cent of Na_2SO_3. Each cc. of tenth-normal iodine represents 0.006308 Gm. of Na_2SO_3.

Sodium Tartrate, Neutral, $Na_2C_4H_4O_6.2H_2O$—Transparent crystals, very soluble in water, insoluble in alcohol. An aqueous solution (1 in 20) gives no reaction for *ammonia, sulphate, or heavy metals.* An aqueous solution (1 in 40) gives no reaction for *chloride.*

Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$—Use *Sodii Thiosulphas.*

Sodium Tungstate, $Na_2WO_4.2H_2O$—Colorless crystals or crystalline lumps, or a white, crystalline powder. An aqueous solution (1 in 40) gives no reaction for *chloride or sulphate.* The loss in weight after gentle ignition does not exceed 12 per cent.

Stannous Chloride, $SnCl_2.2H_2O$—Colorless crystals, very soluble in water, the aqueous solutions requiring a slight excess of hydrochloric acid to prevent the formation of basic chloride. An aqueous solution (1 in 50) gives no reaction for *sulphate.* When tested for *arsenic* (page 1512), 0.3 Gm. of stannous chloride produces no stain. A solution of 0.2 Gm. in 1 cc. of distilled water and 0.5 cc. of hydrochloric acid does not become opalescent upon diluting with 20 cc. of distilled water (*lead*).

Starch, Potato—The starch separated from the tubers of *Solanum tuberosum* Linné (Fam. *Solanaceæ*). A more or less finely granular powder, consisting of starch grains of characteristic shape and appearance when examined microscopically.

Sucrose, $C_{12}H_{22}O_{11}$—Use *Sucrosum.*

Sulphanilic Acid, $C_6H_4NH_2(SO_3H)2H_2O$—Colorless, acicular, efflorescent crystals. Slightly soluble in water. Residue upon incineration, not over 0.05 per cent. A hot, aqueous solution (1 in 25) gives no reaction for *sulphate.*

Sulphosalicylic Acid, $C_6H_3(OH)(SO_3H).COOH$—Colorless needles, soluble in water and in alcohol. Melting point, about 120° C.

Sulphur, S—Use *Sulphur Præcipitatum.*

Sulphuric Acid, H_2SO_4—Use *Acidum Sulphuricum.*

Sulphuric Acid, Concentrated, H_2SO_4—In addition to the description and tests under *Acidum Sulphuricum,* page 560, it complies with the following tests: It contains not less than 94 per cent and not more than 97 per cent of H_2SO_4. Residue upon ignition not to exceed 0.001 per cent. Dilute 1 volume of the acid with 4 volumes of distilled water: no stain is produced by 25 cc. of this dilute acid when subjected to the test for *arsenic,* page 1512. An aqueous solution (1 in 10) gives no reaction for *nitrate* when tested with diphenylamine.

Sulphuric Acid, Diluted—Use *Acidum Sulphuricum Dilutum.*

Sulphuric Acid, Fuming, $H_2SO_4.SO_3$—A heavy, fuming, colorless, oily liquid. It contains at least 84.5 per cent of total SO_3, corresponding to about 15 per cent of free SO_3. Specific gravity about 1.870 at 25° C. Residue upon ignition, not over 0.01 per cent. An aqueous solution (1 in 10) gives no reaction for *nitrate.*

Assay—Cautiously add about 1 cc. of fuming sulphuric acid, accurately weighed, to 100 cc. of distilled water, and titrate with normal sodium hydroxide, methyl orange T.S. being used as indicator. Each cc. of normal sodium hydroxide corresponds to 0.040035 Gm. of SO_3.

Sulphurous Acid, H_2SO_3—An aqueous solution having the odor of sulphur dioxide. A 10 cc. portion of sulphurous acid gives no reaction when subjected to the test for *arsenic.*

Assay—Add about 2 Gm. of sulphurous acid, accurately weighed, to 50 cc. of tenth-normal iodine and allow it to stand for five minutes. Then titrate with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.003203 Gm. of SO_2. It shows not less than 6 per cent of SO_2.

Tannic Acid—Use *Acidum Tannicum.*

Tartaric Acid, $C_2H_2(OH)_2(COOH)_2$—Use *Acidum Tartaricum.*

Tin, Sn—Tin, in the form of granules or irregular fragments. Digest 5 Gm. of tin with 40 cc. of nitric acid until entirely converted into the oxide, then evaporate to dryness. Stir the residue with 25 cc. of distilled water and filter. To the filtrate add 1 cc. of diluted sulphuric acid, evaporate on a water bath as completely as possible, and add 10 cc. of distilled water. No weighable residue remains undissolved (*lead*). When converted into stannous chloride by the action of hydrochloric acid, it complies with the tests under that salt.

Toluene (*Toluol*), $C_6H_5.CH_3$—A colorless, highly refractive, inflammable liquid. Insoluble in water, miscible with alcohol, ether, chloroform, carbon disulphide, and petroleum benzin. Specific gravity about 0.865 at 25° C. Boiling point, about 111° C.

Trinitrophenol, $C_6H_2(OH)(NO_2)_3$—Use *Trinitrophenol.*

Turmeric—The dried root of *Curcuma longa,* Linné, Fam. *Scitaminaceæ,* reduced to a fine powder.

Xylene, C_8H_{10}—A colorless, transparent liquid. Boiling point, 137° to 140° C. Specific gravity, about 0.85 at 25° C.

Yeast, Compressed—The moist, living cells of *Saccharomyces cerevisiæ* Meyen (Fam. *Saccharomycetaceæ*) or of other species of *Saccharomyces,* combined with a starchy or absorbent base. White or yellowish-white, soft and easily broken masses, having a characteristic, slightly sour odor, and not more than a faintly acid reaction to litmus paper. When examined under the microscope, numerous saccharomyces, and also oidium and mycoderma cells and starch grains are visible. Compressed yeast must not be used unless fresh, and free from mildew and musty or foul odors.

Zinc, Zn—Zinc in the form of globules, irregular fragments, granules, or a fine powder, the latter being known as zinc dust. The stain from 10 Gm. of zinc when determined by a blank experiment as directed under the test for *arsenic,* page 1512, is barely perceptible. It contains not more than 0.08 per cent of *iron.*

Zinc Oxide, ZnO—In addition to the description and tests under *Zinci Oxidum,* page 694, it should contain not more than 0.003 per cent of *chloride.*

Test Solutions

Wherever convenient or possible the strength of the following test solutions has been adjusted approximately to normality basis, which signifies that 1 liter of the solution contains a quantity of the reacting substance chemically equivalent to 1 Gm. of hydrogen. It is indicated by the symbol **N.** or **1 N.** Multiples or subdivisions of this ratio are expressed by appropriate numerals, fractions or decimals as **4 N., N/10, 0.5 N.,** etc. Reagents are usually stored in small glass-stoppered bottles (see Fig. 544).

FIG. 544

Reagent bottle

Albumin Test Solution—Carefully separate the white from the yolk of a hen's egg, strictly fresh, having a specific gravity of not less than 1.07. Shake the white thoroughly with 100 cc. of distilled water until thoroughly mixed and all but the chalaza has undergone solution; then filter. This solution must be freshly made when required.

Ammonia Test Solution—Use *Aqua Ammoniæ.*

Ammonia Test Solution, Alcoholic—A solution of ammonia gas in alcohol. A clear, colorless liquid having a strong odor of ammonia. Specific gravity, about 0.80 at 25° C. When assayed by the method directed under *Aqua Ammoniæ,* it shows not less than 9 per cent and not more than 11 per cent by weight of NH_3.

Preserve in glass-stoppered bottles in a cool place.

Ammonia Test Solution, Stronger—Use *Aqua Ammoniæ Fortior.*

Ammonium Carbonate Test Solution—Dissolve 20 Gm. of reagent ammonium carbonate and 20 cc. of ammonia T.S. in sufficient distilled water to make 100 cc.

Ammonium Chloride Test Solution (2 N.)—Dissolve 10.5 Gm. of reagent ammonium chloride, in sufficient distilled water to make 100 cc.

Ammonium Molybdate Test Solution—Dissolve 6.5 Gm. of finely powdered molybdic acid in a mixture of 14 cc. of distilled water and 14.5 cc. of stronger ammonia T.S. Cool the solution and add it slowly to a well-cooled mixture of 32 cc. of nitric acid, and 40 cc. of distilled water. Allow the solution to stand for twenty-four hours and then filter through asbestos. The reagent deteriorates upon standing and it must be rejected if, upon the addition of 2 cc. of sodium phosphate T.S. to 5 cc. of the solution, an abundant yellow precipitate does not form at once or after slight warming. Preserve in the dark; if a precipitate forms, use only the clear decanted solution.

Ammonium Oxalate Test Solution (0.5 N.)—Dissolve 3.5 Gm. of ammonium oxalate in sufficient distilled water to make 100 cc.

Ammonium Polysulphide Test Solution—A yellow liquid, made by saturating ammonium sulphide T.S. with sulphur.

Ammonium Sulphide Test Solution—Saturate 3 volumes of ammonia T.S. with hydrogen sulphide and add to it 2 additional volumes of ammonia T.S. Residue upon ignition, not over 0.05 per cent. The solution is not rendered turbid by either magnesium sulphate T.S. (*free ammonia*) or by calcium chloride T.S. (*carbonate.*) It must be rejected when it shows an abundant precipitate of sulphur. Sodium sulphide T.S. may be used when ammonium sulphide T.S. is directed.

Preserve in small, well-filled, dark amber-colored bottles, in a cool, dark place.

Aniline Sulphate Test Solution—Dissolve 5 cc. of aniline sulphate in 51 cc. of diluted alcohol and add sufficient distilled water to make 100 cc.

Barium Chloride Test Solution (1 N.)—Dissolve 12 Gm. of barium chloride in sufficient distilled water to make 100 cc.

Barium Hydroxide Test Solution (0.5 N.)—A saturated solution (about 8 per cent) of barium hydroxide in recently boiled distilled water. This solution must be freshly made when required for use.

Barium Nitrate Test Solution (0.5 N.)—Dissolve 6.5 Gm. of barium nitrate in sufficient distilled water to make 100 cc.

Bromine Test Solution (*Bromine Water*)—An approximately saturated aqueous solution of bromine, prepared by agitating 2 cc. of bromine with 100 cc. of cold distilled water in a glass-stoppered bottle, the stopper of which should be lubricated with petrolatum. Preserve in a cool place, protected from light.

Cadmium Chloride Test Solution (1 N.)—Dissolve 11 Gm. of cadmium chloride in sufficient distilled water to make 100 cc.

Calcium Chloride Test Solution (1 N.)—Dissolve 7.5 Gm of calcium chloride in sufficient distilled water to make 100 cc.

Calcium Hydroxide Test Solution (0.04 N.)—Use the official *Liquor Calcii Hydroxidi.*

Calcium Sulphate Test Solution (0.03 N.)—A saturated solution (about 0.25 per cent) of calcium sulphate in distilled water.

Chloral Test Solution—Dissolve 50 Gm. of chloral hydrate in 15 cc. of distilled water and 10 cc. of glycerin.

Chlorinated Soda Test Solution—Use *Liquor Sodæ Chlorinatæ.*

Chlorine Test Solution (*Chlorine Water*)—Place 10 Gm. of manganese dioxide in a 500 cc. flask connected by a suitable tube with a small wash bottle containing 50 cc. of distilled water, and connect this by a delivery tube leading to the bottom of a bottle having a capacity of 1000 cc. and containing 400 cc. of distilled water, which has previously been boiled and allowed to cool. Add to the dioxide in the generating flask 25 cc. of hydrochloric acid, previously diluted with 25 cc. of distilled water, stopper the generating flask, and apply a gentle heat by means of a sand bath. Conduct the generated chlorine through the water contained in the wash bottle into the bottle containing the water, which should be loosely stoppered with purified cotton and kept, during the operation, at a temperature of about 10° C. When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating, until the water is saturated. Finally, pour the chlorine water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled. Chlorine T.S., even when kept from light and air, is apt to deteriorate. When required of full strength, it must be freshly prepared.

Preserve in a dark, cool place.

Cobaltous Chloride Test Solution (0.16 N.)—Dissolve 2 Gm. of cobaltous chloride in 1 cc. of hydrochloric acid and sufficient distilled water to make 100 cc.

Cupric Acetate Test Solution—Dissolve 0.1 Gm. of cupric acetate in sufficient distilled water to make 100 cc, adding a few drops of acetic acid, if necessary, to make a clear solution.

Cupric Ammonium Sulphate Test Solution—To cupric sulphate T.S. add ammonia T.S., drop by drop, until the precipitate at first formed is nearly but not completely redissolved, then allow to settle and decant the clear solution. This solution must be freshly made when required.

Cupric Oxide, Test Solution, Ammoniated (*Schweitzer's Reagent*)—Dissolve 10 Gm. of cupric sulphate, in 100 cc. of distilled water, add just sufficient 20 per cent sodium hydroxide solution to precipitate the copper hydroxide, collect the latter on a filter, and wash free from sulphate. Then dissolve the purified, moist precipitate in the minimum quantity of ammonia T.S. necessary for complete solution.

Cupric Sulphate Test Solution (1 N.)—Dissolve 12.5 Gm. of cupric sulphate in sufficient distilled water to make 100 cc.

Denigè's Reagent—Use *Mercuric Sulphate, T.S.*.

Diphenylamine Test Solution—Dissolve 0.5 Gm. of diphenylamine in 100 cc. of reagent sulphuric acid, diluted with 20 cc. of distilled water. The solution should be colorless.

Ferric Ammonium Sulphate Test Solution (0.5 N.)—Dissolve 8 Gm. of reagent ferric ammonium sulphate in sufficient distilled water to make 100 cc.

Ferric Chloride Test Solution (1 N.)—Dissolve 9 Gm. of ferric chloride in sufficient distilled water to make 100 cc.

Ferrous Sulphate Test Solution—Dissolve 8 Gm. of clear crystals of ferrous sulphate in about 100 cc. of distilled water, which has been freshly boiled. This solution must be freshly prepared when required.

Ferrous Sulphate Test Solution, Acid (0.5 N.)—Dissolve 7 Gm. of ferrous sulphate in crystals in 90 cc. of distilled water, which has been freshly boiled and cooled, and then add sufficient sulphuric acid to make 100 cc. This solution must be freshly prepared when required.

Formaldehyde Test Solution—Use *Liquor Formaldehydi.*

Fuchsin-Sulphurous Acid Test Solution—Dissolve 0.2 Gm. of fuchsin in 120 cc. of hot distilled water, cool the solution, add a solution of 2 Gm. of anhydrous sodium sulphite in 20 cc. of distilled water, and follow by 2 cc. of concentrated hydrochloric acid. Then dilute the solution with distilled water to 200 cc. and allow to stand for one hour before use. This solution must be frequently prepared.

Gelatin Test Solution—Dissolve 1 Gm. of gelatin in 50 cc. of distilled water, with the aid of gentle heat, and filter, if necessary. Prepare freshly when required.

Gold Chloride Test Solution (0.2 N.)—Dissolve 1 Gm. of reagent gold chloride in 35 cc. of distilled water.

Hydrogen Dioxide Test Solution—Use *Liquor Hydrogenii Dioxidi.* This reagent must contain at least 3 per cent, by weight, of H_2O_2 when used.

Hydrogen Sulphide Test Solution—A saturated aqueous solution of hydrogen sulphide, made by passing H_2S into cold distilled water. Keep the solution in small, dark amber-colored bottles, filled nearly to the top. Do not use unless it retains a strong odor of H_2S, and, when added to an equal volume of ferric chloride T.S., it produces at once a copious precipitate of sulphur. Preserve in a cool, dark place.

Hypophosphorous Acid Test Solution—Use *Acidum Hypophosphorosum.*

Indigo Carmine Test Solution—Dissolve 1 Gm. of sodium indigotindisulphonate in 150 cc. of distilled water.

Iodine and Potassium Iodide Test Solution—Dissolve 0.5 Gm. of iodine and 1.5 Gm. of potassium iodide in 25 cc. of distilled water.

Iodine Test Solution—Use the tenth-normal iodine volumetric solution, page 1556.

Iodobromide Test Solution—(For use in determining iodine absorption value). Dissolve 13.2 Gm. of reagent iodine in 1000 cc. of glacial acetic acid, with the aid of

a gentle heat if necessary. Cool the solution to 25° C. and determine the iodine content in 20 cc. by titration with tenth-normal sodium thiosulphate, then add to the remainder of the solution a quantity of bromine chemically equivalent to that of the iodine present. Preserve in glass-stoppered bottles, protected from light.

Lead Acetate Glass Wool—Immerse glass wool in a mixture of equal parts of lead acetate T.S. and distilled water, and remove the excess of liquid by pressing it between folds of filter paper. It should be freshly prepared when required for a test.

Lead Acetate Test Paper—Immerse strips of heavy white filter paper, 6 mm. in width and 8 cm. in length, in a mixture of equal parts of lead acetate T.S. and distilled water, drain off the excess of liquid and dry the paper on glass in an oven at 100° C., avoiding contact with metal.

Lead Acetate Test Solution (0.5 N.)—Dissolve 9.5 Gm. of clear, transparent crystals of lead acetate, in sufficient freshly boiled distilled water to make 100 cc. Preserve in well-stoppered bottles.

Lead Acetate Test Solution, Alcoholic (0.1 N.)—Dissolve 2 Gm. of clear, transparent crystals of lead acetate in sufficient alcohol to measure 100 cc.

Preserve in well-stoppered bottles.

Lead Acetate Test Solution, Basic—Dilute 4 Gm. of solution of lead subacetate (page 738) with enough distilled water, previously boiled and cooled, to make the product weigh 100 Gm. Preserve in small, well filled, and tightly-stoppered bottles.

Locke-Ringer's Solution:

Reagent Sodium Chloride	9.000 Gm.
Reagent Potassium Chloride	0.420 Gm.
Reagent Calcium Chloride, crystals	0.240 Gm.
Reagent Magnesium Chloride	0.005 Gm.
Sodium Bicarbonate	0.500 Gm.
Dextrose	0.500 Gm.
Water, freshly distilled from a hard glass flask	
To make	1000 cc.

The solution must be made up each day. The constituents (except the dextrose) may be made up in more concentrated stock solutions and diluted as needed.

Magnesia Mixture Test Solution—Dissolve 5.5 Gm. of magnesium chloride and 7 Gm. of reagent ammonium chloride in 65 cc. of distilled water, add 35 cc. of ammonia T.S., set the mixture aside for a few days in a well-stoppered bottle, and then filter. If not perfectly clear, filter the solution before using.

Magnesium Sulphate Test Solution (1 N.)—Dissolve 12 Gm. of magnesium sulphate in sufficient distilled water to make 100 cc.

Manganese Sulphate Test Solution (1 N.)—Dissolve 11 Gm. of manganese sulphate in 50 cc. of distilled water and add sufficient sulphuric acid to make 100 cc.

Mayer's Reagent—See *Mercuric Potassium Iodide T.S.*.

Mercuric Bromide Test Paper—Cut stiff, heavy quantitative filter paper (see Filter Paper, Quantitative, page 1533) into strips 3 mm. in width and about 12 cm. in length. Immerse these strips for five minutes in alcoholic mercuric bromide T.S. (see below). Remove the excess of solution by pressing the strips between filter paper and then dry them quickly on glass in an oven heated to 100° C. Place at once in a glass-stoppered, wide-mouthed bottle, and protect from light.

Mercuric Bromide Test Solution, Alcoholic (0.3 N.)—Dissolve 5 Gm. of mercuric bromide in 100 cc. of alcohol, employing a gentle heat to facilitate solution.

Preserve in glass-stoppered bottles, and protect from light.

Mercuric Chloride Test Solution (0.5 N.)—Dissolve 6.5 Gm. of mercuric chloride in sufficient distilled water to make 100 cc.

Mercuric Nitrate Test Solution (4 N.)—Dissolve 40 Gm. of red mercuric oxide in a mixture of 32 cc. of nitric acid and 15 cc. of distilled water.

Preserve in glass-stoppered bottles, protected from light.

Mercuric Potassium Iodide Test Solution (*Mayer's Reagent*)—Dissolve 1.358 Gm. of mercuric chloride in 60 cc. of distilled water, and 5 Gm. of potassium iodide in 10 cc. of distilled water. Mix the two solutions and then add sufficient distilled water to make 100 cc.

Mercuric Potassium Iodide Test Solution, Alkaline (*Nessler's Reagent*)—Dissolve 10 Gm. of potassium iodide in 10 cc. of distilled water, and add gradually, in portions, a saturated aqueous solution of mercuric chloride, with constant agitation until a slight red precipitate remains undissolved. To this mixture add 30 Gm. of potassium hydroxide, and, after solution has taken place, add 1 cc. additional of the saturated aqueous solution of mercuric chloride. Dilute this solution with distilled water until it measures 200 cc. Allow the precipitate to subside and draw off the clear liquid. A 2 cc. portion of this reagent when added to 50 cc. of distilled water containing 0.05 mgm. of ammonia, produces at once a yellowish-brown coloration.

Mercuric Sulphate Test Solution (*Denigè's Reagent*)—Mix 5 Gm. of yellow mercuric oxide with 40 cc. of distilled water and while stirring add 20 cc. of sulphuric acid, then add 40 cc. additional distilled water, and stir until completely dissolved.

Mercurous Nitrate Test Solution (0.5 N.)—Mix 20 Gm. of mercury with 10 cc. of nitric acid and 10 cc. of distilled water, in a porcelain dish and set it aside for twenty-four hours in a cool, dark place. Separate and drain the crystals of mercurous nitrate and dissolve 15 Gm. of the crystals in a mixture of 90 cc. of distilled water and 10 cc. of diluted nitric acid.

Preserve in a dark amber-colored bottle in which a small globule of mercury is placed.

Metaphenylenediamine Hydrochloride Test Solution—Dissolve 1 Gm. of metaphenylenediamine hydrochloride in 200 cc. of distilled water: the solution is colorless. If necessary, decolorize by heating with freshly carbonized animal charcoal.

Naphthylamine Acetate Test Solution—Dissolve 0.5 Gm. of reagent naphthylamine acetate in 100 cc. of 30 per cent acetic acid and filter quickly through purified cotton.

Preserve in well-stoppered bottles, protected from light.

Nessler's Reagent—Use *Mercuric Potassium Iodide T. S., Alkaline* (see above).

Oxalic Acid Test Solution (1 N.)—Dissolve 6.8 Gm. of oxalic acid in sufficient distilled water to measure 100 cc.

Palladous Chloride Test Solution—Dissolve 0.5 Gm. of palladous chloride in sufficient distilled water to measure 10 cc.

Preserve in glass-stoppered bottles.

Phenol Disulphonic Acid Test Solution—Dissolve 2.5 Gm. of colorless phenol in 15 cc. of reagent concentrated sulphuric acid in a flask of suitable capacity. Add 7.5 cc. of fuming sulphuric acid, stir well, and heat for two hours at 100° C. Transfer the product, while still fluid, to a glass-stoppered bottle, and, when desired for use, warm in a water bath until liquefied.

Phloroglucinol Test Solution—Dissolve 0.5 Gm. of phloroglucinol in 25 cc. of alcohol.

Preserve in a tightly-stoppered bottle, protected from light.

Picric Acid Test Solution (*Trinitrophenol Test Solution*)—Dissolve 1 Gm. of picric acid in 100 cc. of hot distilled water. Cool the solution and filter, if necessary.

Platinic Chloride Test Solution (0.5 N.)—Dissolve 2.6 Gm. of platinic chloride in sufficient distilled water to make 20 cc.

Potassium Acetate Test Solution—Dissolve 10 Gm. of potassium acetate in sufficient distilled water to make 100 cc.

Potassium Carbonate Test Solution (1 N.)—Dissolve 7 Gm. of reagent anhydrous potassium carbonate in sufficient distilled water to make 100 cc.

Potassium Chromate Test Solution—Dissolve 10 Gm. of potassium chromate in sufficient distilled water to make 100 cc.

Potassium Dichromate Test Solution (1 N., based on the basicity of CrO_3.)—Dissolve 7.5 Gm. of potassium dichromate in sufficient distilled water to make 100 cc.

Potassium Ferricyanide Test Solution (1 N.)—Dissolve 1 Gm. of potassium ferricyanide in 10 cc. of distilled water. The solution must be freshly prepared when required.

Potassium Ferrocyanide Test Solution (1 N.)—Dissolve 10 Gm. of potassium ferrocyanide in sufficient distilled water to make 100 cc.

Potassium Hydroxide Test Solution (1 N.)—Dissolve 6.5 Gm. of potassium hydroxide in sufficient distilled water to make 100 cc.

Potassium Hydroxide Test Solution, Alcoholic—Use half-normal alcoholic potassium hydroxide.

Potassium Iodide Test Solution (1 N.)—Dissolve 16.5 Gm. of potassium iodide in sufficient distilled water to make 100 cc.

Preserve in dark amber-colored, well-stoppered bottles.

Potassium Permanganate Test Solution—Use tenth-normal potassium permanganate.

Potassium Sulphate Test Solution—Dissolve 1 Gm. of potassium sulphate in sufficient distilled water to make 100 cc.

Potassium Thiocyanate Test Solution (*Potassium Sulphocyanate Test Solution*)—Use tenth-normal potassium thiocyanate.

Pyrogallol Test Solution, Alkaline—Dissolve 0.5 Gm. of pyrogallol in 2 cc. of distilled water, and 12 Gm. of potassium hydroxide in 8 cc. of distilled water. The solutions should be freshly prepared and mixed immediately before using.

Resorcinol Test Solution—Dissolve 1 Gm. of resorcinol in sufficient reagent concentrated hydrochloric acid to make 100 cc.

Silver Ammonium Nitrate Test Solution—Dissolve 1 Gm. of silver nitrate in 20 cc. of distilled water and add ammonia T.S., drop by drop, agitating the mixture until the precipitate at first produced is almost but not entirely redissolved, and filter.

Preserve in dark amber-colored, well-stoppered bottles.

Silver Nitrate Test Solution—Use tenth-normal silver nitrate.

Silver Sulphate Test Solution—Mix 1 Gm. of silver sulphate with 100 cc. of distilled water in a glass-stoppered bottle and shake the mixture thoroughly. Decant the clear solution when required for use.

Sodium Acetate Test Solution (1 N.)—Dissolve 13.6 Gm. of sodium acetate in sufficient distilled water to make 100 cc.

Sodium Bisulphite Test Solution—Dissolve 30 Gm. of sodium bisulphite in sufficient distilled water to make 100 cc. Should the solution possess a strong odor of

sulphur dioxide, add sodium hydroxide T.S., drop by drop, until the odor becomes barely perceptible. The solution must be freshly prepared when required.

Sodium Bitartrate Test Solution (1 N.)—Dissolve 9 Gm. of sodium bitartrate in 100 cc. of distilled water. The solution must be freshly prepared when required.

Sodium Carbonate Test Solution (2 N.)—Dissolve 12.5 Gm. of monohydrated sodium carbonate in sufficient distilled water to make 100 cc.

Sodium Cobaltic Nitrite Test Solution—Dissolve 4 Gm. of cobaltous chloride and 10 Gm. of sodium nitrite in about 50 cc. of distilled water, add 2 cc. of acetic acid, and dilute with sufficient distilled water to make 100 cc. This reagent must not be kept longer than three months. It may be preserved for this length of time by the occasional addition of a few drops of acetic acid.

Sodium Cyanide Test Solution (2 N.)—Dissolve 1 Gm. of sodium cyanide in sufficient distilled water to make 10 cc. The solution must be freshly prepared when required.

Sodium Hydroxide Test Solution (1 N.)—Dissolve 4.3 Gm. of sodium hydroxide in sufficient distilled water to make 100 cc.

Sodium Hydroxide Test Solution, Special—This solution is to be prepared of the same strength as *Liquor Sodii Hydroxidi*, page 618, employing sodium hydroxide, which, in addition to the tests prescribed under *Sodii Hydroxidum*, should show not more than 0.005 per cent of *chloride* determined by the turbidimetric test, page 1520.

Sodium Hypobromite Test Solution—To a solution of 40 Gm. of sodium hydroxide in 150 cc. of distilled water, add 10 cc. of bromine, and, after solution has taken place, add sufficient distilled water to make 200 cc. The solution must be freshly prepared when required.

Sodium Nitroprusside Test Solution—Dissolve 1 Gm. sodium nitroprusside in sufficient distilled water to make 20 cc. This solution must be freshly prepared when required.

Sodium Phosphate Test Solution (1 N.)—Dissolve 12 Gm. of clear crystals of sodium phosphate in sufficient distilled water to make 100 cc.

Sodium Phosphotungstate Test Solution—To a solution of 20 Gm. of sodium tungstate in 100 cc. of distilled water, add sufficient phosphoric acid to impart a strongly acid reaction to litmus paper, and filter. When required for use, decant the clear solution from any sediment that may be present.

Preserve the solution in amber-colored, glass-stoppered bottles.

Sodium Sulphide Test Solution (1 N.)—Dissolve 12 Gm. of sodium sulphide in sufficient distilled water to make 100 cc.

NOTE—Sodium sulphide T.S. may be used in all cases when ammonium sulphide T.S. is directed. The solution must be freshly prepared when required for use.

Sodium Tartrate Test Solution (1 N.)—Dissolve 11.5 Gm. of sodium tartrate in sufficient distilled water to make 100 cc.

Sodium Thiosulphate Test Solution—Use the official tenth-normal sodium thiosulphate.

Stannous Chloride Test Solution—Dissolve 1.5 Gm. of stannous chloride in 10 cc. of distilled water containing a few drops of hydrochloric acid.

Preserve the solution in a glass-stoppered bottle in which a fragment of reagent tin has been placed. The solution must be renewed at frequent intervals.

Stannous Chloride Test Solution, Acid—Dissolve 40 Gm. of stannous chloride in 60 cc. of reagent concentrated hydrochloric acid.

Preserve in a glass-stoppered bottle.

Starch Test Solution—Triturate 1 Gm. of reagent starch with 10 cc. of cold distilled water, add sufficient boiling distilled water, with constant stirring, to make 200 cc., then boil the mixture until a thin, translucent fluid is obtained. The solution must be freshly prepared and filtered, if necessary.

Starch-Potassium Iodide Test Solution—Dissolve 0.5 Gm. of potassium iodide in 100 cc. of freshly prepared starch T.S. This solution should be made not longer than twenty-four hours before use.

Sulphanilic Acid Test Solution—Dissolve 0.8 Gm. of sulphanilic acid in 100 cc. of a 30 per cent solution of acetic acid. Preserve in well-stoppered bottles.

Sulphuric Acid Test Solution—Use *Acidum Sulphuricum Dilutum.*

Tannic Acid Test Solution—Dissolve 1 Gm. of tannic acid in 1 cc. of alcohol, and add sufficient distilled water to measure 10 cc. This solution should be freshly prepared when required for use.

Tartaric Acid Test Solution (4 N.)—Dissolve 6 Gm. of tartaric acid in sufficient distilled water to measure 20 cc. This solution should be freshly prepared.

Trinitrophenol Test Solution—See *Picric Acid T.S.*

Turmeric Test Paper—Impregnate sheets of white filter paper with turmeric T.S., dry, and cut into strips of a suitable size. Preserve in well-stoppered bottles.

Turmeric Test Solution—Digest 20 Gm. of powdered turmeric with 4 successive portions of 100 cc. each of cold distilled water, decanting the clear liquid portion each time and discarding it. Then dry the residue at a temperature not over 100° C., and digest it with 100 cc. of alcohol for several days, and filter. Turmeric turns yellow with acids, and brown with alkalies. It is unsuitable for ordinary titrations, being used for special tests.

Volumetric Solutions

It is absolutely necessary that the measuring vessels employed in the operations of volumetric analysis (burettes, flasks, mixing cylinders, pipettes, etc.,) shall agree accurately among themselves in their graduation at the standard temperature selected. All volumetric solutions, if practicable, should be prepared at the standard temperature of 25° C. and used in titrations at that standard temperature. If a titration is made at a markedly different temperature, a volumetric solution should be used which has been standardized for such temperature. In case graduated apparatus calibrated at 25° C. is not procurable, volumetric solutions may be prepared at the temperature for which the apparatus in hand was graduated (*e.g.*, 15° C. or 20° C.), and all such volumetric solutions should be marked to indicate the temperature at which they have been standardized. Such solutions must be used as above stated at the temperature at which the apparatus is standardized, care being taken that all graduated apparatus used be standardized at the same temperature.

Units of Capacity—The units of volume employed by this Pharmacopœia must accord with its standard liter at 25°C., which represents the volume occupied by 996.04 Gm. of distilled water, weighed in air with brass weights, at a temperature of 25° C.* and barometer at 760 mm. To secure uniformity among the various forms of apparatus employed, the standard specifications of the U. S. Bureau of Standards should be adhered to as closely as possible, except that the temperature adopted is 25° C. The tables for calibrating graduated apparatus will be found in the U.S.P.X.

Measuring Flasks—Standard measuring flasks are calibrated to contain, when filled to the mark, 1000, 500, 250, 200, or 100 cc., at 25° C. The necks must be of uniform caliber, and measure in diameter not less than 14 mm. and not more than 20 mm. for 1000 cc. capacity; from 12 mm. to 18 mm. for 500 cc. capacity; from 10 mm. to 15 mm. for 250 cc. capacity, and from 8 mm. to 12 mm. for 100 cc. capacity. The capacity mark on any of these flasks should be not less than 6 cm. distant from the mouth and not less than 2 cm. from the base of the neck (see Fig. 545).

Fig. 545

Volumetric flask

Cylinders—These should be graduated to contain their respective volumes at the standard temperature. Their inside diameter must not be more than one-fifth the graduated length.

Transfer Pipettes—These should be graduated to deliver at standard temperature the exact volume of fluid indicated. The suction stem should be at least 16 cm. long, and the delivery tube not less than 3 cm. and not more than 25 cm. long. The inside diameter at the capacity mark must not be less than 2 mm. and must not exceed 4 mm. for those of 25 cc. capacity. The capacity mark should not be more than 6 cm. from the bulb. The outlet of any transfer pipette should be of such size that the free outflow for water shall last not more than one minute, and not less than fifteen seconds for 5 cc., twenty seconds for 10 cc., and thirty seconds for 50 cc. After filling, the fluid adhering to the outside should be wiped from the stem; then when draining the contents, the pipette should be held in a vertical position; finally, to complete the emptying, the tip of the pipette should be held against the side of the vessel, permitting the last portions of the fluid to flow out by gravity. Pipettes should never be drained by blowing into them, except the Ostwald pipettes, which are especially graduated for use in this way.

Burettes—These must be provided with glass stopcocks and be graduated for

*500 cc. would weigh 498.02 Gm.; 250 cc., 249.01 Gm.; 100 cc., 99.604 Gm.

use at the standard temperature. Burettes provided with rubber tubes and pinch-cocks in place of glass stop-cocks may be used for potassium and sodium hydroxide V.S. The tips should be gradually tapered from 2 to 3 cm. in length and slightly bent. The rate of outflow should be regulated so that not less than 2 seconds should be consumed for each cc. delivered. When completing titration, the tip of the delivery tube should be touched with the wet surface of the receiving vessel to complete the emptying.

General Directions—All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should be thoroughly cleaned prior to use, and rinsed first with distilled water, and then with two or three small portions of the solution that they are to contain. In all apparatus where the surface of the fluid is limited by a meniscus, the reading must be made from the lowest point of the meniscus unless the liquid is too opaque to permit exact observation of that point. It is of the utmost importance that the inner surface of all measuring apparatus shall be free from any suggestion of greasiness.

Normal Volumetric Solutions $\left(\frac{N}{1}\right)$ are those which contain in 1000 cc., in any stated reaction, the chemical equivalent of 1.008 Gm. of hydrogen. If the molecule of the reagent is univalent, one liter will contain a weight in grams equal to the molecular weight of the reagent; if bivalent, a weight in grams equal to one-half its molecular weight; if trivalent, a weight in grams equal to one-third its molecular weight. Thus, hydrochloric acid, $HCl = 36.47$, having but one H atom replaceable by a basic element, has 36.47 Gm. of HCl in 1000 cc. of the normal volumetric solution; while sulphuric acid, $H_2SO_4 = 98.09$, having two replaceable H atoms, contains only one-half this number, or 49.045 Gm. of H_2SO_4 in 1000 cc. of its normal solution. Potassium hydroxide, $KOH = 56.11$, has but one K to replace one H in acids, hence its normal solution contains 56.11 Gm. of KOH in one liter. Again, one molecule of potassium dichromate ($K_2Cr_2O_7 = 294.20$) in oxidation liberates three atoms of oxygen which are capable of combining with six atoms of hydrogen. Therefore, each molecule of the dichromate, yielding three atoms of oxygen, is equivalent to six atoms of hydrogen. Hence, the normal solution should contain $\frac{294.20}{6}$ or 49.0333 Gm. in 1000 cc. Two molecules of potassium permanganate, $2KMnO_4 = 316.06$, in oxidation, give off five atoms of O, which are equivalent to ten atoms of H; hence its normal solution should contain $\frac{316.06}{10}$ or 31.606 in 1000 cc. Solutions containing in 1000 cc. one-tenth of the quantity of the active reagent in the normal solution are called tenth-normal (decinormal) $\left(\frac{N}{10}\right)$ (normality = 0.1); those containing one one-hundredth, hundredth-normal (centinormal) $\left(\frac{N}{100}\right)$ (normality = 0.01); those containing one-fiftieth, fiftieth-normal $\left(\frac{N}{50}\right)$ (normality = 0.02); those containing twice the amount, double-normal $\left(\frac{2N}{1}\right)$ (normality = 2); half the amount half-normal $\left(\frac{N}{2}\right)$ (normality = 0.5). Solutions containing quantities of the active reagent having no simple relation to the molecular weight are called empirical. The general policy has been followed to limit the factors of volumetric solutions to four significant figures.

Use of Empirical Solutions—As it is difficult to maintain the theoretical standard strength with many volumetric solutions, it is not absolutely necessary that such standard strength be maintained, or even attained originally. A solution of approximately the desired normality is prepared and its strength accurately determined.

The correction factor of the normality is applied in all calculations where the empirical solution is employed. As many volumetric solutions are subject to alteration in strength on keeping, their strength should frequently be ascertained.

When the same kind of volumetric solution of several normalities is used, the details of the preparation and standardization are given for the strength most frequently required. Stronger or weaker solutions are prepared and standardized in the same manner as the solutions described, using proportionate amounts of material. Whenever convenient, it is preferable to prepare tenth or lower normality solutions by properly diluting the stronger volumetric solutions, but in preparing any alkali hydroxide volumetric solution by dilution, its exact strength must be ascertained by the same method of titration as described under the stronger solution.

Alkaline Cupric Tartrate Volumetric Solution

FEHLING'S SOLUTION

A. The Copper Solution—Dissolve 34.66 Gm. of carefully selected, small crystals of cupric sulphate, showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of distilled water to make the solution measure exactly 500 cc. at standard temperature. Keep this solution in small, well-stoppered bottles.

B. The Alkaline Tartrate Solution—Dissolve 173 Gm. of crystallized potassium and sodium tartrate and 50 Gm. of sodium hydroxide in a sufficient quantity of distilled water to make the solution measure exactly 500 cc. at standard temperature. Keep the solution in small, rubber-stoppered bottles.

For use, mix exactly equal volumes of the two solutions at the time required.

NOTE: In this Pharmacopœia Fehling's Solution is not used as a volumetric reagent, but is used qualitatively. The correct formula is given for the volumetric solution, because of its extensive use in this manner. It must always be used under carefully standardized conditions in quantitative work, and in connection with tables which will be found in "Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists."

Barium Hydroxide, Tenth-Normal

$Ba(OH)_2.8H_2O = 315.51$ 15.776 Gm. in 1000 cc.

Dissolve about 18 Gm. of reagent barium hydroxide in 1000 cc. of recently boiled and cooled distilled water, and, if necessary, filter the solution quickly.

Ascertain the exact strength by titration against tenth-normal hydrochloric acid, phenolphthalein T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality. This solution deteriorates rapidly and should be standardized before using.

Preserve the solution in rubber-stoppered bottles provided with a soda-lime tube as directed under normal sodium hydroxide.

One cubic centimeter of Tenth-Normal Barium Hydroxide is the equivalent of:

	Gram
Barium Hydroxide, $Ba(OH)_2.8H_2O$	0.01578
Ammonium Benzoate, $NH_4C_7H_5O_2$	0.01391
Ammonium Salicylate, $NH_4C_7H_5O_3$	0.01551

	Gram
Benzoic Acid, $HC_7H_5O_2$	0.01221
Hydrochloric Acid, HCl	0.03647
Salicylic Acid, $HC_7H_5O_3$	0.01381
Sodium Benzoate, $NaC_7H_5O_2$	0.01441
Sulphuric Acid, H_2SO_4	0.004904

Bromine, Tenth-Normal

KOPPESCHAAR'S SOLUTION

Br = 79.92 7.992 Gm. in 1000 cc.

Dissolve 3 Gm. of potassium bromate and 50 Gm. of potassium bromide in sufficient distilled water to make 1000 cc.

Ascertain its exact strength by titration against tenth-normal sodium thiosulphate after the addition of potassium iodide and a slight excess of hydrochloric acid, and adjust to exact normality or to a known strength of approximate normality.

Preserve in dark amber-colored, glass-stoppered bottles.

One cubic centimeter of Tenth-Normal Bromine is the equivalent of:	Gram
Bromine, Br	0.007992
Phenol, C_6H_5OH	0.001568
Resorcinol, $C_6H_4(OH)_2$	0.001835
Sodium Phenolsulphonate, anhydrous, $NaC_6H_5O_4S$	0.004903
Sodium Phenolsulphonate, crystallized, $NaC_6H_5O_4S.2H_2O$	0.005804

Hydrochloric Acid, Normal

HCl = 36.47 36.47 Gm. in 1000 cc.

Mix 95 cc. of hydrochloric acid with sufficient distilled water to measure 1000 cc.

Ascertain its exact strength by titration against freshly standardized sodium carbonate or normal sodium hydroxide, methyl orange T.S. being used as indicator; or gravimetrically by precipitation as silver chloride, and adjust to exact normality or to a known strength of approximate normality.

One cubic centimeter of Normal Hydrochloric Acid is the equivalent of:	Gram
Hydrochloric Acid, HCl	0.03647
Barium Hydroxide, $Ba(OH)_2.8H_2O$	0.1578
Calcium Carbonate, $CaCO_3$	0.05004
Calcium Hydroxide, $Ca(OH)_2$	0.03705
Calcium Oxide, CaO	0.02804
Potassium Hydroxide, KOH	0.05611
Sodium Borate, anhydrous, $Na_2B_4O_7$	0.1008
Sodium Borate, crystallized, $Na_2B_4O_7.10H_2O$	0.1909
Sodium Cacodylate, anhydrous, $Na(CH_3)_2.AsO_2$	0.16002
Sodium Hydroxide, NaOH	0.04001

NOTE: Normal hydrochloric acid is in every respect equivalent in neutralizing power to normal sulphuric acid (page 1565), and may be employed, except in special cases, for the same purposes.

Hydrochloric Acid, Half-Normal

HCl = 36.47 — 18.235 Gm. in 1000 cc.

One cubic centimeter of Half-Normal Hydrochloric Acid is the equivalent of:

	Gram
Hydrochloric Acid, HCl	0.01824

Other factors are identical with those under Half-normal Sulphuric Acid, page 509.

Hydrochloric Acid, Fiftieth-Normal

HCl = 36.47 — 0.7294 Gm. in 1000 cc.

One cubic centimeter of Fiftieth-Normal Hydrochloric Acid is the equivalent of:

	Gram
Hydrochloric Acid, HCl	0.0007294

This volumetric solution is not used officially for titration but is employed in connection with the special Turbidimetric Test, page 1520.

Iodine, Tenth-Normal

I = 126.92 — 12.692 Gm. in 1000 cc.

Method I. Dissolve 12.692 Gm. of reagent iodine in a solution of 18 Gm. of potassium iodide in 100 cc. of distilled water. Then add sufficient distilled water to make the solution measure exactly 1000 cc. at 25° C. Unless freshly prepared its normality should always be redetermined before use.

Preserve in glass-stoppered bottles.

Method II. Tenth-normal iodine may also be prepared as follows:

Dissolve about 14 Gm. of reagent iodine in a solution of 18 Gm. of potassium iodide in about 100 cc. of distilled water, diluting finally to 1000 cc. Carefully measure from a burette 25 cc. of this solution (which is too concentrated), into a flask, then add gradually and cautiously from a burette tenth-normal sodium thiosulphate, shaking constantly, until the color of the solution is but slightly yellow, then add a few drops of starch T.S. and continue the addition of the tenth-normal sodium thiosulphate until the blue color is just discharged. Note the number of cc. of the tenth-normal sodium thiosulphate consumed, and then dilute the iodine solution so that 25 cc. will require for decolorization exactly 25 cc. of the tenth-normal sodium thiosulphate at standard temperature.

One cubic centimeter of Tenth-Normal Iodine is the equivalent of:

	Gram
Iodine, I	0.01269
Acetone, $(CH_3)_2CO$	0.0009677
Antimony and Potassium Tartrate, crystallized, $K(SbO)C_4H_4O_6.\frac{1}{2}H_2O$	0.01662
Arsenic, in arsenous compounds, As	0.003748
Arsenous Iodide, AsI_3	0.02279
Arsenic Trioxide (Arsenous Acid), As_2O_3	0.004948
Calcium Sulphide, CaS	0.003607
Iron, Fe	0.002792
Mercurous Chloride, HgCl	0.02361
Mercurous Iodide, HgI	0.03275
Mercury (in mercurous compounds), Hg	0.02006

	Gram

Sodium Sulphite, anhydrous, Na_2SO_3	0.006303
Sodium Thiosulphate, anhydrous, $Na_2S_2O_3$	0.01581
Sodium Thiosulphate, crystallized, $Na_2S_2O_3.5H_2O$	0.02482
Sulphur Dioxide, SO_2	0.003203

Oxalic Acid, Tenth-Normal

$H_2C_2O_4.2H_2O = 126.06$ 6.303 Gm. in 1000 cc.

Dissolve 6.45 Gm. of reagent oxalic acid in sufficient distilled water to measure 1000 cc. Ascertain its exact strength by titration against freshly standardized tenth-normal sodium hydroxide, phenolphthalein T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality.

One cubic centimeter of Tenth-Normal Oxalic Acid is the equivalent of:	Gram
Oxalic Acid, crystallized, $H_2C_2O_4.2H_2O$	0.006303
Ammonia Gas, NH_3	0.001703
Calcium Carbonate, $CaCO_3$	0.005004

Lead Oxide, PbO	0.01116
Lead Peroxide, PbO_2	0.01196
Lead Subacetate, approximately, $Pb_2O(C_2H_3O_2)_2$	0.01371
Manganese Dioxide, MnO_2	0.004347
Potassium Hydroxide, KOH	0.005611
Potassium Permanganate, $KMnO_4$	0.003161
Sodium Hydroxide, NaOH	0.004001

Potassium Dichromate, Tenth-Normal

$K_2Cr_2O_7 = 294.20$ 4.9033 Gm. in 1000 cc.

Method I. Dissolve 4.9033 Gm. of potassium dichromate, which has been pulverized and dried to constant weight at 120° C., in sufficient distilled water to measure exactly 1000 cc. at standard temperature.

Method II. Tenth-normal potassium dichromate may also be prepared as follows:

Dissolve about 5 Gm. of potassium dichromate in 1000 cc. of distilled water, transfer exactly 25 cc. of this solution to a 500 cc. glass-stoppered flask, add 2 Gm. of potassium iodide (free from iodate), dilute with 200 cc. of distilled water, add 5 cc. of hydrochloric acid, allow to stand for ten minutes in a dark place, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. at the end of the titration as indicator. Adjust to exact normality or to a known strength of approximate normality.

For estimating ferrous iron, it is used in the following manner. Introduce an acidulated aqueous solution of the ferrous compound into a flask. Gradually add the tenth-normal potassium dichromate from a burette with agitation until a drop placed

upon a white porcelain surface no longer becomes blue when mixed with a drop of freshly prepared potassium ferricyanide T.S. Several closely agreeing determinations should be made before finally calculating the result.

One cubic centimeter of Tenth-Normal Potassium Dichromate is the equivalent of:

	Gram
Potassium Dichromate, $K_2Cr_2O_7$	0.004903
Ferrous Carbonate, $FeCO_3$	0.01159
Ferrous Sulphate, anhydrous, $FeSO_4$	0.01519
Ferrous Sulphate, crystallized, $FeSO_4.7H_2O$	0.02780
Iron, in ferrous compounds, Fe	0.005584
Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$	0.02482

Potassium Hydroxide, Dekanormal

KOH = 56.11 561.1 Gm. in 1000 cc.

Prepare and preserve as directed under normal potassium hydroxide.

NOTE: This solution is intended specifically for the ready measurement of definite amounts of absolute potassium hydroxide, hence it is not necessary to adjust the solution to exact strength, but the factor of strength must be accurately known and the solution used accordingly. The use of barium hydroxide in this solution is unnecessary, provided the solution be allowed to settle before standardizing and only the clear liquid employed.

Potassium Hydroxide, Normal

KOH = 56.11 56.11 Gm. in 1000 cc.

Normal Potassium Hydroxide is used only as an alternative solution. It is prepared and standardized in exactly the same manner as normal sodium hydroxide, using an equivalent quantity of the base for preparing the solution.

The factors for this solution are the same as for normal sodium hydroxide which is preferred on account of its economy.

Potassium Hydroxide Alcoholic, Half-Normal

KOH = 56.11 28.055 Gm. in 1000 cc.

Dissolve 2.5 Gm. of silver nitrate in 5 cc. of distilled water and add the solution to 1200 cc. of alcohol in a glass-stoppered bottle, and mix thoroughly. Dissolve 5 Gm. of potassium hydroxide in 25 cc. of warm alcohol, cool the solution, and pour it slowly, without stirring, into the alcoholic solution of silver nitrate. Let the mixture stand until the precipitated silver oxide has settled, filter, and distil. Dissolve about 35 Gm. of potassium hydroxide in 20 cc. of distilled water and add sufficient alcohol, purified as above, to make 1000 cc. Allow the solution to stand in a tightly stoppered bottle (using either a glass or rubber stopper) for twenty-four hours, then quickly decant the clear supernatant liquid into a bottle provided with a well-fitting rubber stopper. Ascertain the strength by titration against a hot solution of reagent potassium bitartrate, phenolphthalein T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality. The strength may also be ascertained and adjusted after titration against half-normal hydrochloric acid.

NOTE: This solution should be kept in bottles provided with well-fitting stoppers of rubber, or of cork which have been well coated with paraffin, and it should be protected from light. It should be restandardized whenever it is used. It is very important that this solution should be used at the same temperature at which it was standardized.

One cubic centimeter of Half-Normal Alcoholic Potassium Hydroxide is the equivalent of:

	Gram
Potassium Hydroxide, KOH	0.02806
Borneol, $C_{10}H_{17}OH$	0.07710
Bornyl Acetate, $C_{10}H_{17}.C_2H_3O_2$	0.09811
Linalyl Acetate, $C_{10}H_{17}.C_2H_3O_2$	0.09811
Menthol, $C_{10}H_{19}OH$	0.07811
Menthyl Acetate, $C_{10}H_{19}.C_2H_3O_2$	0.09912
Methyl Salicylate, $CH_3.C_7H_5O_3$	0.07605
Potassium Bitartrate, $KHC_4H_4O_6$	0.09408
Santalol, $C_{15}H_{24}O$	0.1101

Potassium Permanganate, Tenth-Normal

$KMnO_4 = 158.03$ 3.1606 Gm. in 1000 cc.

Dissolve about 3.3 Gm. of potassium permanganate in 1000 cc. of distilled water in a flask and boil for about five minutes. Close the flask with absorbent cotton and allow it to stand for at least two days, then pour off the clear portion of the solution or filter through asbestos. The water for preparing and diluting this solution should be freshly distilled after adding about 1 Gm. of potassium permanganate to each liter of water in the retort before beginning the distillation. Ascertain its exact strength by titration against reagent sodium oxalate, and adjust to exact normality or to a known strength of approximate normality.

The strength may also be determined and adjusted by titrating against tenth-normal sodium thiosulphate after the addition of diluted sulphuric acid and an excess of potassium iodide.

Burettes provided with glass stop-cocks must be employed when titrating with this solution. It should be frequently restandardized. Preserve in glass-stoppered bottles.

One cubic centimeter of Tenth-Normal Potassium Permanganate is the equivalent of:

	Gram
Potassium Permanganate, $KMnO_4$	0.003161
Calcium Oxide, CaO (as oxalate)	0.002804
Ferrous Carbonate, $FeCO_3$	0.01159

Silver Nitrate, $AgNO_3$	0.01699
Silver Oxide, Ag_2O	0.01159

Silver Nitrate, Tenth-Normal

$AgNO_3 = 169.89$ 16.989 Gm. in 1000 cc.

Method I. In a flask containing 10.788 Gm. of silver and provided with a small funnel inserted into the neck to prevent loss by spurting, introduce gradually about 30 cc. of nitric acid, or sufficient for complete solution. After thoroughly rinsing the funnel, transfer the clear solution, with the rinsings, to a beaker or porcelain dish, and evaporate to dryness on a water bath, carefully protecting the vessel from dust. Then dry in an oven at about 120° C. for ten minutes, cool the residue, and dissolve it in 1000 cc. of distilled water at 25° C.

Method II. The solution may also be made by dissolving 17.006 Gm. of thoroughly dried silver nitrate in enough distilled water to make 1000 cc..

Strontium Iodide, anhydrous, SrI_2	0.01707
Strontium Iodide, crystallized, $SrI_2.6H_2O$	0.02248
Zinc Chloride, $ZnCl_2$	0.006815

Sodium Hydroxide, Dekanormal

NaOH = 40.01 400.1 Gm. in 1000 cc.

Prepare and preserve as directed under normal sodium hydroxide.

NOTE: This solution is intended specifically for the ready measurement of definite amounts of absolute sodium hydroxide, hence it is not necessary to adjust the solution to exact strength, but the factor of strength must be accurately known and the solution used accordingly. The use of barium hydroxide in this solution is unnecessary, provided the solution be allowed to settle before standardizing and only the clear liquid employed.

Sodium Hydroxide, Double-Normal

$NaOH = 40.01$ 80.02 Gm. in 1000 cc.

Preserve the solution as directed under normal sodium hydroxide (see below). This solution should be frequently restandardized.

Sodium Hydroxide, Normal

$NaOH = 40.01$ 40.01 Gm. in 1000 cc.

Dissolve 45 Gm. of sodium hydroxide in about 950 cc. of distilled water and add a freshly prepared saturated solution of reagent barium hydroxide until no more precipitate forms. Allow the precipitate to subside, decant the clear liquid or filter the solution, and determine its strength by titration against a hot solution of an accurately weighed quantity of reagent potassium bitartrate, or against normal hydrochloric or sulphuric acid, and adjust to exact normality or to a known strength of approximate normality.

NOTE: Solutions of alkali hydroxides absorb carbon dioxide when exposed to the atmosphere. They should therefore be preserved in bottles with well-fitting rubber stoppers, provided with tubes filled with a mixture of sodium hydroxide and lime (soda-lime tubes) so that air in entering the container must pass through such tubes which will absorb the carbon dioxide.

The solution should be frequently restandardized.

One cubic centimeter of Normal Sodium Hydroxide is the equivalent of:	Gram
Sodium Hydroxide, NaOH	0.04001
Acetic Acid, $HC_2H_3O_2$	0.06004
Acetic Anhydride, $(CH_3CO)_2O$	0.05104
Ammonia Gas, NH_3	0.01703
Boric Acid, H_3BO_3	0.06192
Chloral Hydrate, $CCl_3CHO.H_2O$	0.1654
Citric Acid, crystallized, $H_3C_6H_5O_7.H_2O$	0.07004

Potassium Bitartrate, $KHC_4H_4O_6$	0.09408
Potassium Hydroxide, KOH	0.02806
Sodium Bitartrate, $NaHC_4H_4O_6.H_2O$	0.09504
Sulphuric Acid, H_2SO_4	0.02452
Sulphuric Anhydride, SO_3	0.02002
Tartaric Acid, crystallized, $H_2C_4H_4O_6$	0.03752
Trichloracetic Acid, $CCl_3.COOH$	0.08170

Sodium Hydroxide, Tenth-Normal

$NaOH = 40.01$ 4.001 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide, page 1562. This solution should be frequently restandardized.

One cubic centimeter of Tenth-Normal Sodium Hydroxide is the equivalent of:

	Gram
Sodium Hydroxide, $NaOH$	0.004001
Cinchophen, $C_6H_5.C_9H_5N.COOH$	0.02492
Eucaine Hydrochloride, $C_{15}H_{21}O_2N.HCl$	0.02837
Lactic Acid, $HC_3H_5O_3$	0.009006
Potassium Bitartrate, $KHC_4H_4O_6$	0.01882
Potassium Hydroxide, KOH	0.005611
Sulphuric Acid, H_2SO_4	0.004904

Sodium Hydroxide, Fiftieth-Normal

$NaOH = 40.01$ 0.800 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide, page 1562. This solution should be frequently restandardized.

One cubic centimeter of Fiftieth-Normal Sodium Hydroxide is the equivalent of:

	Gram
Sodium Hydroxide, NaOH	0.0008002
Potassium Bitartrate, $KHC_4H_4O_6$	0.003763
Sulphuric Acid, H_2SO_4	0.0009808

Sodium Hydroxide, Hundredth-Normal

$NaOH = 40.01$ 0.400 Gm. in 1000 cc.

Preserve as directed under normal sodium hydroxide. This solution should be frequently restandardized.

One cubic centimeter of Hundredth-Normal Sodium Hydroxide is the equivalent of:

	Gram
Sodium Hydroxide, NaOH	0.0004001
Potassium Bitartrate, $KHC_4H_4O_6$	0.001882
Sulphuric Acid, H_2SO_4	0.0004904

Sodium Thiosulphate, Tenth-Normal

$Na_2S_2O_3.5H_2O = 248.20$ 24.820 Gm. in 1000 cc.

Dissolve 30 Gm. of sodium thiosulphate in sufficient distilled water, previously boiled for twenty minutes in a flask of hard glass and quickly cooled, to measure 1000 cc. Ascertain its exact strength by titration against tenth-normal potassium dichromate, in the presence of an excess of potassium iodide and a small amount of sulphuric acid, and adjust to exact normality, or to a known strength of approximate normality. The strength may also be ascertained and adjusted after titration against tenth-normal iodine. This solution should be frequently restandardized.

One cubic centimeter of Tenth-Normal Sodium Thiosulphate is the equivalent of:

	Gram
Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$	0.02482
Arsenic, As (in Arsphenamine and Neoarsphenamine)	0.003748
Bromine, Br	0.007992
Chlorine, Cl	0.003546
Chlorine, Cl (in Chloramine and Dichloramine)	0.001773
Chromium Trioxide, CrO_3	0.003333
Cupric Sulphate, anhydrous, $CuSO_4$	0.01596
Cupric Sulphate, crystallized, $CuSO_4.5H_2O$	0.02497
Iodine, I	0.01269
Iodine, I (in Thymol Iodide and Calcium Iodobehenate)	0.002115
Iron, Fe, in ferric salts	0.005584
Lead Peroxide, PbO_2	0.01196
Potassium Bromate, $KBrO_3$	0.002784
Potassium Dichromate, $K_2Cr_2O_7$	0.004903
Sodium Arsenate, anhydrous, Na_2HAsO_4	0.009299
Sodium Arsenate, crystallized, $Na_2HAsO_4.7H_2O$	0.01560
Sodium Hypochlorite, NaOCl	0.003723

Sodium Thiosulphate, Two-Hundredth-Normal

$Na_2S_2O_3.5H_2O = 248.20$ 1.241 Gm. in 1000 cc.

This solution should be frequently restandardized.

One cubic centimeter of Two-Hundredth-Normal Sodium Thiosulphate is the equivalent of:

	Gram
Sodium Thiosulphate, $Na_2S_2O_3.5H_2O$	0.001241
Iodine, I	0.0006346
Iodine, I (from Thyroxin and Thyroid Glands)	0.0001058

Sulphuric Acid, Normal

$H_2SO_4 = 98.076$ 49.038 Gm. in 1000 cc.

Add slowly, with constant stirring, 30 cc. of sulphuric acid to 1020 cc. of distilled water and allow the solution to cool to 25° C. Ascertain its exact strength by titration against freshly standardized normal sodium hydroxide, methyl orange T.S. being used as indicator, and adjust to exact normality or to a known strength of approximate normality.

The strength may also be ascertained and adjusted after titration against an accurately weighed amount of reagent anhydrous sodium carbonate. It may also be standardized gravimetrically by precipitation and weighing as barium sulphate.

One cubic centimeter of Normal Sulphuric Acid is the equivalent of:

	Gram
Sulphuric Acid, H_2SO_4	0.04904
Ammonia Gas, NH_3	0.01703
Ammonium Acetate, $NH_4C_2H_3O_2$	0.07707

Strychnine, $C_{21}H_{22}O_2N_2$	0.006686

CHAPTER XCIII

DIAGNOSTICAL REAGENTS AND CLINICAL TESTS

IN THE following pages of Diagnostical Reagents and Clinical Tests it is understood that the standard for official substances like Iodine, Potassium Iodide, Gelatin, Sodium Chloride, etc., are those to be found in the text of the Pharmacopœia or among the reagents. If the solutions are not clear, filter them.

Reagents for Examination of Urine

For Acetone Reaction

Sodium Nitroprusside (used for Legal's test and Lange's test).
Iodine Potassium Iodide Solution (for Lieben's solution):

Potassium Iodide	6 Gm.
Iodine	4 Gm.
Distilled Water, a sufficient quantity, To make	100 cc.

Dissolve the potassium iodide in the distilled water, add the iodine and shake the mixture frequently until a solution is obtained.

Alcoholic Solution of Iodine (10 per cent), for Gunning's reaction. To be freshly prepared.

For Albumin Reaction

Saturated Aqueous Solution of Trinitrophenol.

Esbach's Reagent:

Trinitrophenol	1 Gm.
Citric Acid	2 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

Spiegler-Jolles' Reagent:

Corrosive Mercuric Chloride	2 Gm.
Succinic Acid	4 Gm.
Sodium Chloride	4 Gm.
Distilled Water, a sufficient quantity, To make	100 cc.

Mix the several ingredients and dissolve them in the distilled water.

Tsuchyias' Reagent:

Phosphotungstic Acid	1.5 Gm.
Hydrochloric Acid	5 cc.
Alcohol, a sufficient quantity, To make	100 cc.

Dissolve the phosphotungstic acid in 90 cc. of alcohol with stirring. Add the hydrochloric acid and sufficient alcohol to make 100 cc. If not clear, allow to settle and decant the clear liquid.

For Bile Reactions

UROBILIN

Solution of Zinc Chloride

Zinc Chloride	10 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

Mixture of Zinc Acetate:

Zinc Acetate	10 Gm.
Dehydrated Alcohol, a sufficient quantity, To make	100 cc.

Finely powder the zinc acetate and intimately mix it with the alcohol. Dispense the mixture with directions "to be well shaken before using".

UROBILINOGEN

Ehrlich's Solution:

Paradimethylamidobenzaldehyde	2 Gm.
Hydrochloric Acid	50 cc.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

BILIARY COLOR REACTIONS

Nitric Acid (containing a trace of nitrous acid).

Solution of Calcium Chloride (Hupert's reaction):

Calcium Chloride	10 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

Smith's Reagent:

Tincture of Iodine	10 cc.
Alcohol	90 cc.

For Blood Reaction

Solution of Guaiac:

Guaiac	2 Gm.
Dehydrated Alcohol, a sufficient quantity, To make a solution measuring	100 cc.

Oxygenated Oil of Turpentine.

Ether containing Hydrogen Dioxide.

Aloin, isobarbaloin, containing barbaloin.

For Diacetic Acid Reaction

Solution of Ferric Chloride used for Gerhardt's test.

For Diazo Reaction, Ehrlich

1. Sodium Nitrite	1 Gm.
Distilled Water, a sufficient quantity, To make	200 cc.
2. Sulphanilic Acid	5 Gm.
Hydrochloric Acid	50 cc.
Distilled Water, a sufficient quantity, To make	100 cc.

Dissolve the sulphanilic acid in about 700 cc. of distilled water to which the hydrochloric acid has been added and follow with enough distilled water to make the product measure 1000 cc.

For use, 1 cc. of the sodium nitrite solution should be mixed with 50 cc. of the sulphanilic acid solution.

For Indican Reactions

Solution of Chlorinated Lime:

A saturated solution of chlorinated lime diluted with an equal volume of distilled water and filtered.

Obermeyer's Solution:

Ferric Chloride	0.4 Gm.
Hydrochloric Acid, a sufficient quantity, To make a solution measuring	100 cc.

Solution of Lead Acetate:

Lead Acetate	25 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

For Pentose Reactions

Bial's Reagent:

Orcin	1 Gm.
Hydrochloric Acid	500 cc.
Solution of Ferric Chloride	25 drops

Dissolve the orcin in the hydrochloric acid and add the solution of ferric chloride.

For the Estimation of Urea

Solution of Sodium Hypobromite:

1. Bromine	125 Gm.
Sodium Bromide	125 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	1000 cc.
2. Sodium Hydroxide	225 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	1000 cc.

The reagent should be freshly prepared by mixing equal volumes of solutions 1 and 2 and diluting the resulting mixture with one and a half volumes of distilled water.

For Sugar Reactions

Solution of Sodium Hydroxide:

Sodium Hydroxide	10 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

Solution of Copper Sulphate:

Copper Sulphate	10 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100 cc.

Benedict's Qualitative Reagent:

Copper Sulphate	17.3 Gm.
Sodium Citrate	173.0 Gm.
Sodium Carbonate (anhydrous)	100.0 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	1000.0 cc.

With the aid of heat, dissolve the sodium citrate and carbonate in about 600 cc. of water. Pour (through a folded filter paper if necessary) into a glass graduate and make up to 850 cc. Dissolve the copper sulphate in about 100 cc. of water and make up to 150 cc. Pour the carbonate-citrate solution into a large beaker or casserole and add the copper sulphate solution slowly, with constant stirring. The mixed solution is ready for use and does not deteriorate upon long standing.

Benedict's Quantitative Reagent:

Copper Sulphate Crystals showing no efflorescence	18.00 Gm.
Sodium Carbonate (anhydrous)	74.10 Gm.
Sodium Citrate	200.00 Gm.
Potassium Thiocyanate	125.00 Gm.
Solution Potassium Ferrocyanide, 5 per cent	5.00 cc.
Distilled Water, a sufficient quantity, To make a solution measuring	1000.00 cc.

Dissolve the carbonate, citrate and thiocyanate, with the aid of heat in sufficient water to make about 800 cc. and filter this solution if necessary. Dissolve the copper suphate in about 100 cc. of water and pour this solution slowly and with constant stirring into the first solution. Add the ferrocyanide solution, cool, and dilute with water to exactly 1000 cc.

Of the various ingredients, the copper salt only, need be weighed with exactness.

Twenty-five cc. of Benedict's Reagent will reduce 50 milligrammes of Glucose.

Haines' Solution:

Copper Sulphate	12.00 Gm.
Sodium Hydroxide	32.00 Gm.
Glycerin	90.00 cc.
Distilled Water, a sufficient quantity, To make a solution measuring	1000.00 cc.

Nylander's Reagent:

Sodium Hydroxide	10 Gm.
Potassium and Sodium Tartrate	4 Gm.
Bismuth Subnitrate	2 Gm.
Distilled Water, a sufficient quantity, To make	100 cc.

Dissolve the potassium and sodium tartrate in 90 cc. of distilled water. Add the bismuth subnitrate to the solution, shake the mixture thoroughly and then filter through glass wool. Preserve and dispense this solution in amber-colored bottles.

Fehling's Solution (use Alkaline Cupric Tartrate V.S.).

Pavy's Solution:

1. Copper Sulphate	4.158 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	500.000 cc.
2. Potassium and Sodium Tartrate	20.4 Gm.
Potassium Hydroxide	20.4 Gm.
Stronger Ammonia Water	300.0 cc.
Distilled Water, a sufficient quantity, To make a solution measuring	500.0 cc.

For use, mix equal quantities of the two solutions

Sodium Acetate: Neutral to litmus paper.

Reagents for the Examination of Gastric Contents

Alizarin Solution:

Alizarin yellow R (p-nitrobenzene-azo-salicylic-acid)	0.1 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	1000.0 cc.

Congo Red Test Paper:

Saturate filter paper with an aqueous solution of Congo Red (1 in 1000). Dry and cut the paper into strips and preserve them in well-stoppered glass vials.

Benzidin in Glacial Acetic Acid.

Benzidin Saturated Solution in Alcohol.

Saturated Alcoholic Solution of Methylthionine Chloride (Methylene Blue).

Alcoholic Solution, of Dimethylaminoazobenzene (1 in 200).

Günzburg's Reagent:

Phloroglucinol	2 Gm.
Vanillin	1 Gm.
Alcohol	30 cc.

Dissolve the ingredients in the alcohol.

Tenth-normal Hydrochloric Acid V.S.: Dilute 1 volume of normal hydrochloric acid V.S. with exactly 9 volumes of distilled water.

Phenolphthalein (1 per cent alcoholic).

Solution of Rosolic Acid:

Rosolic Acid	1 Gm.
Alcohol, a sufficient quantity, To make a solution measuring	100 cc.

Carminfibrin:

Heat freshly-drawn beef blood, wash the stringy coagulated fibrin in running water until decolorized, cut the fibrin into small pieces of uniform size and macerate it in alcohol for several days. Then transfer the fibrin for one or two days to a 0.5 per cent ammoniacal solution of carmine, which contains as little excess of ammonia as possible, and keep it cool until the fibrin is thoroughly stained. Wash the product in distilled water until the wash-water is no longer colored, squeeze it out well, and then preserve it in glycerin. Before using carefully wash the carminfibrin in distilled water to free it from glycerin.

Reagents for the Examination of Blood

Hayem's Solution:

For red blood corpuscles:

Sodium Sulphate	5 Gm.
Sodium Chloride	1 Gm.
Corrosive Mercuric Chloride	0.5 Gm.
Distilled Water	200.0 cc.

Dissolve the salts in the distilled water and filter.

Toison's Solution:

Methyl Violet 6B	0.125 Gm.
Sodium Chloride	1.000 Gm.
Sodium Sulphate	8.000 Gm.
Glycerin	30.000 cc.
Distilled Water	300.000 cc.

Dissolve the salts in the distilled water and add the methyl violet and the glycerin.

For white corpuscles:

Acetic Acid (U. S. P.)	1 cc.
Distilled Water	99 cc.

Mix them.

Solution for Hemoglobin Estimation (Sahli's hemometer):

Tenth-normal hydrochloric acid V.S. saturated with chloroform. This solution should always be freshly prepared and be dispensed in dark amber-colored bottles.

Jenner's Stain:

1. Eosin	0.5 Gm.
[1] Methyl Alcohol, a sufficient quantity, To make a solution measuring	100.0 cc.
2. Methylthionine Chloride (Methylene Blue)	0.5 Gm.
[1] Methyl Alcohol, a sufficient quantity, To make a solution measuring	100.0 cc.

For use mix 25 cc. of eosin solution with 20 cc. of methylene blue solution.

Ehrlich's Triacid Stain:

Saturated Aqueous Solution of Orange-G	120 to 125 cc.
Saturated Aqueous Solution of Acid Fuchsin	80 to 165 cc.
Saturated Aqueous Solution of Methylene Green	125 cc.
Distilled Water	300 cc.
Dehydrated Alcohol	200 cc.
Glycerin	100 cc.

Mix.

Wright's Stain:

Sodium Bicarbonate	0.50 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	100.00 cc.
Methylene Blue (Methylthionine Chloride)	0.75 Gm.
Eosin, A, Water-soluble (sodium tetra-bromfluorescein)	0.50 Gm.
Distilled Water, a sufficient quantity, To make a solution measuring	500.00 cc.
Methyl Alcohol (C. P. Neutral, Acetone-Free)	60.00 cc.

[1] Rectified wood alcohol, sp. gr. about 0.812 at 25° C.

Add the methylene blue to the sodium bicarbonate solution and heat one hour in flowing steam. The flask should be of such size and shape that the depth of the fluid does not exceed 2½ inches. When cool, add the eosin solution slowly, stirring constantly, until the blue color is lost and the mixture becomes purple with a yellow metallic luster on the surface and a finely granular black precipitate is formed. Collect the precipitate on a filter. When dry, dissolve 1 Gm. of the precipitate in the 60 cc. of methyl alcohol.

Giemsa's Stain:

Azur II-Eosin	0.3 Gm.
Azur II	0.8 Gm.
Glycerin	250.0 cc.
[1] Methyl Alcohol	250.0 cc.

Dissolve the dyes in the methyl alcohol and add the glycerin and filter.

Stains and Accessories for Use in Connection with the Study of Micro-organisms

Alum-hematoxylin Solution:

Hematoxylin crystals	1.0 Gm.
Saturated Aqueous Solution of Ammonium Alum	100.0 cc.
Distilled Water	300.0 cc.
Thymol	0.5 Gm.

Dissolve the hematoxylin in a little distilled water by the aid of heat, add the other ingredients, and expose the combined solution to the light, in a bottle loosely stoppered, until it has assumed a dark red color, then filter. The thymol is added as a preservative.

Mayer's Hemalum:

Hematein or its ammonium salt	1.0 Gm.
Alcohol, 90 per cent	50.0 cc.
Alum	50.0 Gm.
Distilled Water	1000.0 cc.
Thymol	0.5 Gm.

Dissolve the hematein in the alcohol by the aid of heat, add the thymol, and then this solution to the alum dissolved in the distilled water, and then filter. The thymol is added as a preservative.

Alcoholic Solution of Methyl Violet 6B:

Methyl Violet 6B	10 Gm.
Alcohol, a sufficient quantity, To make a solution measuring	100 cc.

Borax-Methylene Blue Solution:

Methylthionine Chloride (Methylene Blue)	2 Gm.
Boiling Solution of Sodium Borate (1 in 20), a sufficient quantity, To make a solution measuring	100 cc.

Löffler's Methylene Blue Solution:

Methylthionine Chloride (Methylene Blue)	0.5 Gm.
Alcohol	30.0 cc.
Tenth-normal Potassium Hydroxide V.S.	2.0 cc.
Distilled Water	98.0 cc.

Dissolve the methylene blue in the alcohol, add the potassium hydroxide and distilled water.

Solution of Carbol Methyl Violet:

Alcoholic Solution of Methyl Violet 6B	10 cc.
Aqueous Solution of Phenol (1 in 20), a sufficient quantity, To make a solution measuring	100 cc.

Solution of Carbolfuchsin:

Alcoholic Solution of Fuchsin (1 in 10)	10 cc.
Aqueous Solution of Phenol (1 in 20)	100 cc.

Mix.

[1] Rectified wood alcohol, sp. gr. about 0.812 at 25° C.

For Tubercle Bacilli

Gabbett's Acid Blue (For Gabbett's Stain for Tubercle Bacilli)

Methylene Blue (Methylthionine Chloride)	2.0 Gm.
Sulphuric Acid	25.0 cc.
Distilled Water, a sufficient quantity, To make	100.0 cc.

Orth's Acid Alcohol:

Hydrochloric Acid	3.00 cc.
Alcohol	70.00 cc.
Distilled Water, a sufficient quantity, To make	100.00 cc.

Solution of Carbolfuchsin. (See above.)

For Decolorizing

Ebner's Fluid:

Hydrochloric Acid	2.5 cc.
Sodium Chloride	2.5 Gm.
Distilled Water	100.0 cc.
Alcohol	500.0 cc.

Prepare a solution.

Nitric Acid Solution:

Nitric Acid	30 cc.
Distilled Water, a sufficient quantity, To make	100 cc.

Diluted Lugol's Solution (Gram's Iodine Solution):

Iodine	1 Gm.
Potassium Iodide	2 Gm.
Distilled Water, a sufficient quantity, To make	200 cc.

For Counter Staining

Löffler's Methylene Blue Solution.

Gram's Stain (Aniline Water—Methyl Violet 6B Solution):

Aniline oil[1]	15 cc.
Saturated Alcoholic Solution of Methyl Violet 6B	7 cc.
Dehydrated Alcohol	10 cc.
Distilled Water, a sufficient quantity, To make	100 cc.

Shake the aniline with 65 cc. of distilled water for several minutes; filter the resulting opalescent aniline water through a moistened filter, pour the filtrate into a solution prepared by mixing the other liquids and add sufficient distilled water to make 100 cc.

Diluted Carbolfuchsin Solution:

Solution of Carbolfuchsin (see above)	1 cc.
Distilled Water	4 cc.

Prepare a solution.

Culture Media

Bouillon Stock:

Lean Beef	500 Gm.
Or Extract of Beef	3 Gm.
Distilled Water, a sufficient quantity, To make	1000 cc.

Mix thoroughly 500 Gm. of finely minced lean beef with 1000 cc. of cold distilled water, heat it to boiling in a closely covered dish or flask and keep it at that temperature for one

[1] The commercial aniline oil is preferable to pure aniline.

hour. If extract of beef is used to make bouillon stock, boil the solution for one-half hour. Filter the resulting bouillon through a well-wetted filter, until clear and use it as the basis for the following combinations:

Plain Bouillon:

Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the peptone and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to make the mixture neutral to litmus. Then filter the product through a well-wetted filter, fill it into suitable containers and sterilize.

Glucose Bouillon:

Glucose (dry)	10 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the glucose, peptone and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to neutralize the resulting solution. Then filter the product through a well-wetted filter, fill it into suitable containers and sterilize by the discontinuous method.

Plain Gelatin:

Gelatin	100 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the gelatin, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to neutralize the resulting mixture. Filter the warmed product through filter paper, fill it into suitable containers and sterilize by the discontinuous method.

Glucose Gelatin:

Glucose (dry)	10 Gm.
Gelatin	100 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the glucose, gelatin, peptone, and sodium chloride in the bouillon stock by means of heat and add sufficient normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the product through paper, fill it into suitable containers and sterilize by the discontinuous method.

Plain Agar-agar:

Agar	15 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the agar, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, fill it into suitable containers and sterilize.

Glucose Agar-agar:

Glucose (dry)	10 Gm.
Agar	15 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the glucose, peptone, and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, fill it into suitable containers and sterilize by the discontinuous method.

Glycerin Agar-agar:

Glycerin	60 cc.
Agar	15 Gm.
Peptone	10 Gm.
Sodium Chloride	5 Gm.
Normal Sodium Hydroxide V.S.,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the glycerin, agar, peptone and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, fill it into suitable containers and sterilize.

Lactose-litmus Agar-agar:

Sugar of Milk	10 Gm.
Agar	15 Gm.
Peptone	10 Gm.
Sodium Chloride	15 Gm.
Normal Sodium Hydroxide V.S.,	
Azolitmin Test Solution,	
Bouillon Stock, each, a sufficient quantity,	
To make	1000 cc.

Dissolve the sugar of milk, agar, peptone and sodium chloride in the bouillon stock by means of heat and add a sufficient quantity of normal sodium hydroxide V.S. to neutralize the resulting mixture. Then filter the warmed product through paper, add a sufficient quantity of azolitmin solution to impart to the resulting mixture a pale blue color, fill into suitable containers and sterilize by the discontinuous method.

Blood Serum (Löffler's Mixture):

Glucose Bouillon	250 cc.
Horse or Beef Blood Serum	750 cc.

Run the mixture of glucose bouillon and beef or horse blood serum into properly sterilized test tubes, and coagulate it by means of heat so as to form a slanting surface for culture purposes.

PART X

THE MANUFACTURING PHARMACIST

CHAPTER XCIV

CHEMICAL AND MECHANICAL CONTROL IN MANUFACTURING PHARMACY

WHEN a pharmaceutical preparation is manufactured in a retail store or pharmacy, the quantity prepared is usually a relatively small one, and the entire operation is performed by the pharmacist himself, or under his immediate supervision. In a manufacturing plant, where pharmaceutical preparations are made in large quantities, the immediate personal supervision of any one responsible pharmacist or pharmaceutical chemist is obviously impossible. The various steps in the preparation of pills or tablets or an elixir may be performed in different departments of the factory by different groups of men or women working under the direction and supervision of different foremen or sub-foremen. In a factory where pharmaceutical preparations are manufactured on a relatively large scale, it becomes necessary therefore to install a comprehensive supervisory or control system, whereby the identity, purity, and strength of the manufactured preparation sent out into commerce shall be just as surely established as is that of the preparation or prescription made on a small scale by a single responsible operator.

In every establishment where pharmaceutical preparations are manufactured, provision must be made for pharmaceutical testing (see Part IX). The place where this work is done is usually called the *laboratory* or *analytical laboratory*. But in order to carry out the comprehensive system of control mentioned above, the mere possession of an analytical laboratory in which occasional tests and assays are made is far from adequate. A well organized *control department*, of which the analytical laboratory is only a part, but an important part, must be provided.

To insure the proper functioning of such a control department, it is absolutely essential that each department in the plant should harmonize its work with that of every other department and that all work together for the good of the whole. This harmonious relationship so essential to the success of a manufacturing pharmaceutical plant depends largely upon the personnel, or the men and women in charge of the various divisions, subdivisions, and departments which make up the organization, and just to the extent that they are scientifically trained experts in their respective lines of work—pharmacists, chemists, botanists, bacteriologists, physicians, experts in finance, accounting, salesmanship, etc., constituting a *scientific staff*—just to that extent will the work of the control department function smoothly and effectually.

The function of the control department is to assume responsibility for the *identity*, *purity*, and *strength* of everything used in the manufacture of the products of the factory, and to exercise such a watchfulness over all outgoing finished products as to be able to guarantee their *quality*, *strength*, and *conformity to label*.

The equipment of the control department includes the following well defined divisions or departments:

Analytical Laboratory—Because of the widely varying nature and great distribution of materials used in medicine, the variety of testing work required in a pharmaceutical manufacturing plant is greater than in the case of any other line of manufacture requiring chemical control. The analytical laboratory must therefore be equipped for literally all kinds of analytical operations, and must be of a size commensurate with the size of the plant. It should be located in a place quickly accessible to the manufacturing operations of the plant, and yet be sufficiently removed to provide quiet and freedom from the annoyance of factory din and distraction, gases, odors, and vibration. It must be well lighted, both artificially and by sunlight, and be relatively free from dust, an important point if located in a large city.

Physiologic Testing Laboratory—The increasing importance of physiologic assaying and standardization, as evidenced by the several added requirements of the United States Pharmacopœia X, makes a well equipped physiologic testing laboratory an essential part of the control department. Owing to the fact, however, that there are not enough trained experts in this field of work to enable every manufacturing house to do its own physiologic testing, together with the fact that it would not be economically possible to do so, for many years to come much of the required work of this nature will be sent out to experts who have established commercial laboratories for this purpose.

Working Library and Reference Room—To operate a control department successfully, quick reference to all leading authorities is necessary. Since no firm can hope to provide in its own library every publication needed for reference purposes, it follows that plants located near large public and technical libraries of cities and colleges are particularly fortunate. But these cannot take the place entirely of a *control department library*, as complete as the generosity of the firm will permit. Such a working library will contain not merely a complete assortment of the latest reference and textbooks on pharmacy, chemistry, and allied branches, but will also be provided with files of all the current technical journals. Systematic provision should be made for the reading of these journals, as, for example, by the assignment of certain journals to individuals in the department and by the holding of meetings at stated intervals to discuss the articles published in them. Provision should also be made for the card-indexing of all important articles, and for their permanent preservation, either by clipping and filing, or by binding, at the end of each year.

Research Laboratory—When a control department has been established, problems concerning the improvement of manufacturing processes, the recovery and utilization of by-products, the production of new products, etc., will constantly arise. These problems can best be worked out in a properly equipped laboratory adjacent to, but separate from, the analytical laboratory. The research laboratory should be equipped, aside from any specially designed apparatus for the study of special problems, with a complete outfit of apparatus on a small manufacturing scale, so that conditions in the plant may be simulated when necessary.

Control Department Office—Ample provision must be made for the liaison work of the control department. The control department is the clearing house for disputes and provides contacts between the work of all other departments and a meeting place for the harmonizing of all interests. Moreover, a complete system of records must be kept, covering all of the work done in the analytical, physiological, and research laboratories, and these records must always be available at all times. Hence a carefully organized office force must be maintained for the systematic making and filing of all records. In large establish-

ments, this force will consist of a librarian, filing clerks, and stenographers, but in smaller organizations some or all of these positions may be combined.

Organization of Control Department—A fully functioning control department cannot be established in a day or a month or a year. It must grow with the needs of the developing activities of the plant. Usually the control department is managed by the *chief chemist* or *chemical director* of the plant, who maintains direct supervision of the control department office. Chiefs are provided for the analytical, physiological, and research laboratories, and sufficient assistants to carry on the work. One of the first and most important tasks devolving upon the control department, is to establish and adopt *standard methods* for all routine work, so that all workers in the department will obtain their results by uniform methods. Naturally, the methods of the United States Pharmacopœia afford the starting point for this work, but the testing and examination of all products not official in the United States Pharmacopœia or the National Formulary must also be provided for by selected methods which should be changed or modified only after thorough discussion, and approval by the chief of the control department.

Relationship of Control Department to the Plant—In order that the control department may exercise its function as outlined on page 1577 and thus discharge its responsibility, it naturally must establish and maintain certain relationships to other departments of the plant. These may well be divided into three groups, as follows:

Relationship to Purchasing Department—Every manufacturing plant has or should have a centralized purchasing department in charge of a specially trained purchasing agent. In purchasing all supplies, including the crude materials, drugs, and chemicals from which the products of the plant are to be manufactured, this department has three things to bear always in mind: 1. Quality. 2. Peculiar requirements of goods for special purposes. 3. Cost. Of these three, the purchasing department must depend upon the advice of the control department for the first and second, namely *quality* and *peculiar requirements*. Hence the necessity for close touch and complete harmony between these two departments. The control department must have the absolute confidence of the purchasing department, which in turn must be absolutely governed in its purchases by sanction of the control department. *Quality* must always take precedent over considerations of *cost*.

Supplies should as far as possible be purchased from submitted samples, which the purchasing department in turn submits to the control department for examination and advice. This advice must always be followed by the purchasing department, and, since the control department is responsible for the quality of all materials used in the plant, the purchasing department must not arbitrarily change a source of supply, because offered at an advantageous price, without the consent of the control department.

By "*peculiar requirements of goods for special purposes*", the reference is to the fact that each manufacturing plant has its own special preparations in the manufacture of which materials not intrinsically better perhaps than other materials on the market, but differing somewhat from the usual or the ordinary, must be purchased to fill these special wants. In the selection of such materials the purchasing department must be guided absolutely by the advice of the control department.

Relationship to Manufacturing Departments—Since the control department must assume responsibility for the *identity*, *purity*, and *strength* of all materials used in manufacturing, it is highly essential that the rule be adopted that *no purchased material may be used for manufacturing until it has been approved*

by the control laboratory. To this end, it is necessary that a sample be taken from each and every container, bag, bale, box, bottle, barrel, keg, drum, etc., received as crude material for manufacturing purposes, and be submitted to the control laboratory for approval.

In order to carry out this requirement, all manufacturing plants must have one or more centralized *stock departments*. Each lot of goods as it is received is given a *serial number* by which its identity may be insured. A sample from each lot—from each container—is then submitted, properly numbered, dated, and labeled with name, source, and any other information, to the control laboratory. A written report approving or passing these goods, or stating the conditions or proportions in which they may be used, must be received, and the goods so labeled, before they may be supplied for manufacturing purposes.

Naturally, the amount of work done in the control laboratory on these supplies is enormous, covers all phases of analytical operations, and varies greatly with the nature and importance of the substances examined. It may vary also as sources change, with the *probability* of a substance being adulterated or of inferior quality. Much work may be deemed necessary in the case of one substance, a volatile oil for example, and very little work in the case of another substance, crystals of ferrous sulphate for example, but the important fact remains, *viz.*, the control department is responsible for the identity, purity, and strength and there the responsibility rests as to how much or how little work shall be required before the stamp of approval of the control department may be placed upon the goods.

One of the most important duties of the stock department in its relationship to the control laboratory lies in the care which it must exercise in taking the sample for analysis. This is so important that *rules for sampling* must be formulated by the control department who must see that they are properly carried out. Unless the sample sent to the control laboratory for analysis is truly representative of the lot from which it is taken, its examination and approval or rejection is of little value.

Relationship to Sales Department—As the ultimate purpose of the control department is to guarantee the quality, strength, and conformity to label of all outgoing finished products, its relationship to the sales department and through it to the medical profession and the public, is a most important one.

First of all, standards of quality, strength, and excellence must be adopted for all goods manufactured. If they are official in the United States Pharmacopœia or National Formulary, or are described in the pharmacopœias of other countries or by recognized authorities, these descriptions, of course, form the starting point for the standards to be adopted.

Next, samples of all lots of goods manufactured, which are subject or liable to variation, must be sent to the control laboratory for assay and approval. The same *rules for sampling* provided for the stock department must be enforced in the taking of samples of manufactured goods. These samples, properly labeled and serially numbered for future identification, representing lots of completed or partially completed preparations, are then either *approved*, or written directions are given as to what corrections of strength or of quality are necessary to bring them up to standard. If corrections are required and made, new samples must be submitted for approval. Goods may be "finished", *i.e.*, placed in finished package form and labeled, only after the control laboratory approval has been obtained in report form.

In submitting samples of tinctures, fluidextracts, and other liquid preparations for assay, it is generally advisable to prepare the sample intentionally

slightly over-strength, as it is much easier to make the final adjustment to standard by dilution than by fortification.

Considerable diversity of opinion exists in different manufacturing plants as to the products which may be regarded as reasonably free from *liability to variation.* All are agreed, of course, that preparations involving the processes of percolation, evaporation, the application of heat, etc., are subject to variation and hence must be assayed. These groups include tinctures, fluidextracts, solid and powdered extracts, and certain kinds of elixirs, syrups, etc. Again, practically all are agreed that an assay should not be necessary where the manufacture of the preparation requires only simple solution or mixing, with possibly subsequent filtration, especially in view of the fact that all of the entering ingredients have already been approved by the control department.

When preparations are manufactured and sent out in dose form, such as pills, tablets, lozenges, suppositories, etc., there is room for argument as to the necessity for *chemical control* in addition to the *mechanical control* which is automatically applied by the process of manufacture itself.

Illustration of Control Methods—In order that a clearer view of just what is meant by *mechanical control* may be presented, the following brief outline of the steps involved in the manufacture of a compressed medicinal tablet is given. Suppose it is desired to manufacture 70,000 tablets of the following formula:

Acetanilid	$\frac{7}{10}$ gr.
Caffeine	$\frac{1}{10}$ gr.
Sodium Bicarbonate	$\frac{1}{6}$ gr.

A master formula card, kept in the production manager's or superintendent's office contains the formula with full working directions. Fig. 546 is a reproduction of such a master card.

A copy of this card, which may be photographed, or blue-printed, to guarantee accuracy, is sent to the stock department, together with a requisition for all of the supplies or ingredients necessary for the manufacture of this lot. Fig. 547 illustrates such a requisition for supplies.

If the stock department has on hand the necessary quantities of all ingredients which have been approved by the control department, the order is filled—each item being checked in by the stock man with the serial number of the ingredient used in order to check its identity with the control laboratory's records, and the quantities are checked by a competent assistant.

The goods, together with the copy of the master formula card and the requisition for supplies, are then delivered to the granulating department where they are receipted for and again checked. The granulation is then prepared, dried, and sifted, after which it is weighed and the weight entered on the card where it may be compared with the theoretical weight.

The granulation is then passed on to the compressing department where designated amounts of starch as a disintegrator and talc as a lubricant are added, and the mixture is placed in the hopper of the tablet compressing machine. A few tablets are run off, and twenty are taken and carefully weighed to see if the punches have been set properly to deliver the weight of tablet required by the master card. Several adjustments may be necessary to secure the proper weight of twenty tablets, and when this has been accomplished, the entire lot of 70,000 tablets is run off, twenty tablets being taken from time to time and weighed to determine whether the run has been uniform, *i.e.*, that no change has occurred in the set of the punches and that the granulation has continued to feed uniformly into the dies. Finally, the total yield of

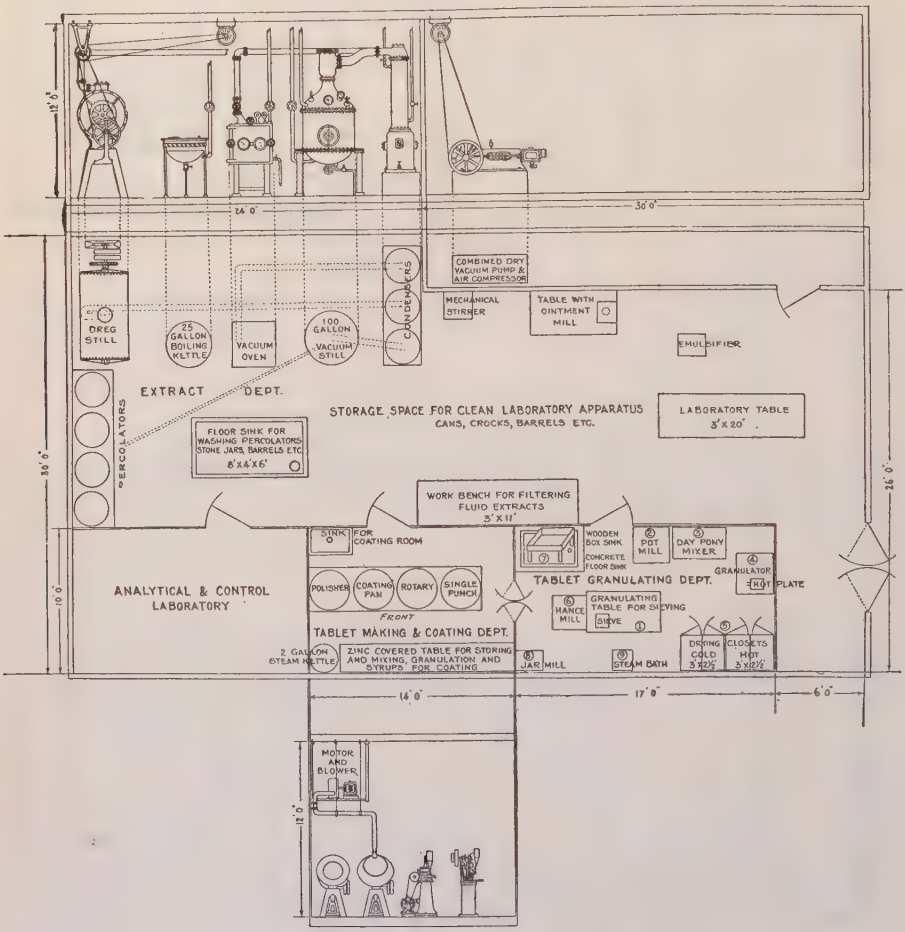
tablets obtained is weighed, and the weight obtained checked against the theoretical yield, a small allowance being permitted for mechanical losses during the process.

When all of these weights check out closely with the theoretical, it must be admitted that the opportunity for variation or error is less than the error which may reasonably be expected in the making of a chemical assay. How-

FIG. 548



The layout of a small pharmaceutical laboratory

ever, it is now considered good practice, particularly in the case of hypodermic tablets, and all tablets of potent remedies, to have the final approval of the lot await the assay by the control laboratory.

The responsibility of the control laboratory to the sales department does not finally end until it has made sure that the outgoing products are "*true to label*". To this end it is often necessary for the control department to see to it that conversely the *labels* and accompanying *circulars* are "true to the product". In other words, an essential duty of the control department is to

take a responsible part in the preparation of all of the labels for manufactured goods. A thorough knowledge of the requirements of the Federal Food and Drugs Act, the several Food and Drugs Acts of the states in which the manufactured products are to be sold, the Federal Insecticide and Fungicide Act, and the Federal Narcotic Law is necessary for this purpose.

Manufacturing Operations on a Large Scale—Most of the large manufacturing pharmaceutical laboratories in this and other countries have developed from small retail pharmacies and the same principles of integrity, accuracy, and care, which are of first consideration at the prescription counter and in the service rendered the physician and community by the retail pharmacist, must dominate the policy of the manufacturing pharmacist, if confidence and success are to be attained.

It is true that the preparation of pharmaceuticals on a large scale introduces many problems not encountered by the small manufacturer and retailer such as those of control, just enumerated. It is also necessary to operate a manufacturing plant with efficiency and economy and these problems are of such importance that efficiency experts have been developed who materially aid in planning and constructing modern laboratories and also in developing better processes of manufacture.

Most of the subjects discussed in this book have direct application to the operations carried out in a manufacturing laboratory. Often, however, they must be modified to meet new conditions, although the principles still apply.

In some parts of this book the operations described are exclusively those carried out on a large scale, such as those requiring a vacuum dryer or a dreg still, or the process of pill or tablet coating, etc. Needless to say the manufacturing pharmacist requires special training and large experience before becoming efficient; but adequate technical training in a college, in the principles of pharmacy, and practical experience in a professional pharmacy has been the foundation for the success of most of the able manufacturing pharmacists of today.

Laboratory Planning—Fig. 548 illustrates an efficient layout or arrangement for a small pharmaceutical laboratory, suitable for commercial or teaching purposes, as planned by Charles S. Herron. It is self-evident that every laboratory must be arranged to meet the specific conditions presented and these will be as varied as the number of laboratories established.

Sales Price Calculation—The necessary factors for correctly determining the price for which a manufactured product may be profitably sold are illustrated by the following typical calculation. Again it must be recognized that conditions will vary with every item and each plant and this example is only offered as an indication of the many factors which must be taken into consideration in determining the right price.

Factors in Calculating a Sales Price—Illustration: A capsule formula.

List of ingredients .....

Take the actual cost (averaged for period) and enter each item separately.

Cost of materials for 7000 capsules, $16.21	
Cost for 1000	$2.32
5 per cent for waste	0.12
Cost of mixing in laboratory	0.08
Cost of 1000 capsules	0.85
Labor in filling capsules (piece work)	0.60
Cost per 1000 (materials and bulk manufacture cost, including direct and indirect labor	$3.97

100

Sales packages are in 500, cost therefore ½ of $3.97 or	$1.99
Finishing cost per bottle (cork, label, labor, and factory overhead	0.14
Actual factory cost of finished package of 500	$2.13

If the business is now based on the following plan:

Net profit	15 per cent	
Salesman's commission	25 per cent	
General overhead and selling expense	20 per cent	
Total	60 per cent	
First cost	40 per cent	= $2.13
Sale price	100 per cent	or $5.33

If there is a 40 per cent discount to be allowed the trade the following calculation must be followed:

Net price to be obtained by manufacturer		$5.33	
Discount to trade, 40 per cent			
Therefore	60 per cent =	5.33	
Discount	40 per cent =	3.55	
List price	100 per cent	$8.88	or $9.00

PART XI

THE PROFESSIONAL AND PRESCRIPTION PHARMACIST

CHAPTER XCV

MAGISTRAL PHARMACY[1]

UNDER this head will be considered the preparation and dispensing of medicines intended to be compounded extemporaneously or as the occasion or the physician's needs may require. It includes a consideration of other subjects, as facts concerning surgical supplies, sterilization, and other distinctly professional services. The subject of official or galenical pharmacy has been considered in previous chapters, the distinction being made that such preparations are intended to be permanent, and are generally made in advance and kept on hand ready for use, while those which are magistral are usually only intended to last during the occasion which calls them into existence.

There are several classes of official medicines in which both permanent and extemporaneous preparations are embraced. These have been divided so that the official formulas are given in Part III but their discussion, from the viewpoint of dispensing pharmacy, will be found under this heading. Examples are found in plasters, powders, ointments, etc. Some of these are often kept on hand ready for use, but the experienced and conscientious prescription pharmacist will recognize deterioration and dispense only such medicinal substances as are of proper quality and freshness and of full therapeutic activity, discarding those which have deteriorated. To carry out such a policy there must be adequate technical training and sufficient equipment for testing and for such manufacturing and dispensing as may be required.

Magistral Pharmacy is unquestionably the most important division of true pharmaceutical practice. It calls for the exercise of more tact, knowledge, and ability than any other activity in the pharmacy. Owing to the fact that the ability to successfully practice extemporaneous pharmacy depends largely upon the personal qualities of the pharmacist, very little can be written upon the subject which would be generally useful. Good training in a college and help from the watchful eye of a skilled pharmacist, and practical experience, will alone give the confidence and knowledge of details that assure success. All that will be attempted under this head will be to collect and arrange such points as have been found useful in the actual practice of present-day pharmacy in the hope that at least some of them may be of service to others. The arrangement of a pharmacy, chiefly from the merchandising viewpoint, has already been presented (see page 1317, etc.), but the arrangement and equipment of the prescription counter and the facilities for other professional services will be specially studied in this section.

[1] The word magistral is derived from *magister*, a master, and is defined as "a term applied to medicines prescribed for the occasion, by a competent person, in distinction from such as are official, or kept prepared in the shops. As the latter are prepared according to a certain formula, an intelligent assistant is generally equal to the task; but the knowledge of a master is needed to give directions for an original preparation". —*Thomas.*

The Form of the Prescription

The word prescription is derived from the Latin word *præscriptio* (*præ*, "before", and *scribo*, "I write"). It may be defined as the formula which a physician writes, specifying the substances he intends to have administered to a patient.

The Latin language is preferred here in writing prescriptions as it is also in Great Britain, Germany, and other European countries. The advantages of the use of Latin in designating the ingredients of the prescription are obvious: 1. It is the language of science, and is understood, to a greater or less extent, throughout the civilized world. 2. It is a dead language, and therefore not subject to the changes that are common to all living forms of speech. 3. The Latin names for medicines are distinctive, and very nearly the same in all countries. 4. It is frequently necessary, and always advisable, to withhold from a patient the names and properties of the medicinal agents administered. This can usually be effected by the use of the Latin technical terms.

The Parts of a Prescription—For the purpose of examination or study, a model prescription may be divided into six parts: 1. *The superscription, or heading.* 2. *The name of the patient.* 3. *The inscription, or the names and quantities of the ingredients.* 4. *The subscription, or the directions to the compounder.* 5. *The signa* (*mark*), *or the directions for the patient.* 6. *The name or initial of the physician, with the date.*

1. **The Superscription, or Heading**—This invariably consists, in Latin prescriptions, of the symbol ℞, which is an abbreviation of the word *recipe* ("take"), the imperative of the Latin verb *recipio*. In French prescriptions the letter *P*, the initial letter of the word *prenez* ("take"), is used.

The use of the inclined stroke upon the tail of the ℞ is traced to a custom, common in the ancient days of superstition, of placing at the top of the prescription an abbreviation, called an invocation, which represented a prayer to a favorite deity. The sign of Jupiter (♃), the chief mythological divinity of the ancient Romans, was usually employed. This was gradually replaced by the letter R; but the last stroke of the symbol of the all-powerful Jove has not yet been surrendered, and it remains as an ornament to the superscription to the present day.

2. **The Name of the Patient**—This is frequently omitted from the prescription through inattention. It should always be placed at the top of the prescription by the prescriber, and should be transferred to the label by the compounder. Serious accidents have sometimes occurred through neglect of this direction, as when an adult dose of a medicine has been given to a child, owing to the similarity of the appearance of an adult's medicine and that of a child, and the name of the patient not appearing on either label.

3. **The Inscription, or the Names and Quantities of the Ingredients**—This part of the prescription is undoubtedly the most important of all, and requires the greatest amount of care. The official titles (see page 17) of the ingredients should always be used for designating those which are official. A model prescription, if it is of the compound class, is presumed to embrace the following: 1. The *basis*, or chief active ingredient. 2. The *adjuvant*, or aid to the basis, to assist its action. 3. The *corrective*, which is intended to qualify the action of the basis and adjuvant. 4. The *vehicle*, the ingredient which serves to "carry all", or hold them together, dilute them, and give to the whole the proper consistence, form and color. This is sometimes called the *diluent*.

The ingredients are occasionally written down by the physician in the order given above; but this rule is frequently deviated from, and they follow in the

order of their importance. This is a matter of small moment to the pharmacist, however, for he always has to consider solubility, compatibility, and other necessary considerations which determine the order, if the prescription is to be compounded properly.

Many prescriptions contain but one or two ingredients, there being no especial need of a corrective, vehicle, or diluent, the tendency of modern therapeutics being against polypharmacy and in the direction of simple and concentrated remedies, or those having positive effects. There are many advantages to be derived, however, from the combination of ingredients, even when these have similar medicinal action.

The name of each ingredient and the quantity attached to it, should occupy but one line, and great care should be observed in abbreviating, to see that the abbreviation is distinctive and not liable to be mistaken for an article not intended by the writer. The cabalistic characters in present use, designating the quantities in a Latin prescription, must be very plainly written, if serious errors are to be avoided.

The method of ascertaining the quantities of each of the constituents generally followed by physicians, is first to write down the names of the ingredients in the proper order, each on a separate line, without affixing the quantities; then having decided upon the total number of doses that are to be given, or the total number of pills, lozenges, capsules, suppositories, etc., by multiplying this by the amount proper to give for the single dose the quantity of the ingredient is obtained.

Method of Allotting Quantities

Parts in Order	℞ Ingredients	No. of Doses	Multiplied by	Single Dose	Quantity of each Ingredient
Basis	Chloralis	16	×	7½ gr.	℥ ii
Adjuvant	Potassii Bromidi	16	×	15 gr.	℥ iv
Corrective	Syrupi Zingiberis	16	×	f℥ ss	f℥ i
Vehicle	Syrupi	16	×	f℥ iss	f℥ iii

Symbolic Characters used in Latin Prescriptions—Although the subject of weights and measures is treated in the earlier chapters of this work, the special characters used in prescriptions, with their values attached, may be appropriately recalled in this connection. They are as follows:

M, *Minim*, $\frac{1}{60}$ of a fluidrachm
gtt., *Gutta*, a drop; plural, *guttæ*, drops
gr., *Granum*, a grain; plural, *grana*, grains
ss, *Semis*, a half
℈, *Scrupulus*, a scruple (20 grains)[1]
℥, *Drachma*, a drachm (60 grains)
f℥, *Fluidrachma*, a fluidrachm (60 minims)
℔, *Uncia*, a troyounce (480 grains)
f℥, *Fluiduncia*, a fluidounce (8 fluidrachms)
lb, *Libra*, a pound, rarely used in prescriptions (5760 grains)
O, *Octarius*, a pint (16 fluidounces)

The Roman numerals are used to designate quantities—i, ii, iii, iv, v, vi, vii, viii, ix, x, xx, xxx, xl, l, lx, lxx, lxxx, xc, c, etc. These are always written after the ingredient, as Sacchari ℥iv. Care should be taken to dot the i's in each case, to avoid possible errors. The "j" is sometimes used in place of "i" where more than one "i" is needed at the end of the quantity; thus,

[1]This weight is rapidly passing out of use. It is quite as convenient to write gr. xx, and this is not likely to be mistaken for ℥, as ℈ is.

"gr. ij", meaning two grains. The "j" is oftener written like an elongated "i"; thus, "ij".

4. **The Subscription, or the Directions to the Compounder**—The progress made in pharmacy is well shown by the present custom of omitting specific directions to the compounder. In the vast majority of prescriptions the subscription is contracted to a single letter or word, as *M.*, or *misce; S.*, or *solve; F., fiat,* etc. The physician relies upon the skill of the pharmacist, and generally gives no specific directions.

5. **The Signa, or Directions for the Patient,** sometimes called Signatura, is usually abbreviated *Sig.* or *S.* Formerly these directions were written in Latin, but this is rarely the case now, except in Great Britain. There is, indeed, no good reason for writing them in Latin. The Latin which is in common use in prescription writing is idiomatic, and, although the ordinary rules of Latin grammar are generally applicable to it, many of the terms have a special meaning, and it differs in several respects from classical Latin, and hence has to be a special object of study. The directions should be known to the patient and should be written in the vernacular on the label in a clear, distinct hand. *The careless habit of not specifying the directions, by writing, "As dir." for "As directed" or "Use as directed", is greatly to be deprecated.* Frequently the patient forgets the verbal directions, or misunderstands them, and asks the pharmacist, "How is this medicine to be taken?" The answer must of necessity be as worthless as the direction, unless the pharmacist by skilful questioning can cause the directions to be recalled by the patient. Then, again, the dose of the prescription gives the only clue to its safety. Without knowing it, the pharmacist cannot be held responsible for not detecting an error. The patient even if he remembers at the time the verbal directions may soon forget them, and afterwards take a double dose by mistake. The directions for the patient should be written in full, explicitly, and in plain English.

6. **The Name or Initials of the Physician with Date**—The name of the prescriber is rarely signed in full, particularly since the very general use of printed prescription blanks, which contain not only the full name and address of the physician but also his office hours. It is very necessary sometimes to communicate quickly with the physician in case of error or ambiguity, and, when printed blanks are not used, the name and address of the prescriber should be written in full.

Unusual Doses in Prescriptions—It is to be regretted that some uniform system of indicating unusual doses has not been adopted by physicians. Occasions frequently arise where the patient, either from becoming habituated to its use, or from some other cause, will tolerate an excessive or ordinarily poisonous dose of a remedy. A careful pharmacist always hesitates to compound such a prescription if the dose is not especially marked as unusual, and delays necessarily occur. The most satisfactory method of indicating such a dose is that of underscoring the quantity deemed unusual, as shown in the following:

℞ Morph. Sulph. gr. vi
Syrup. Limonis f℥ ii
Aquæ q. s. ft. f℥ i.

Sig. A teaspoonful every two hours until relieved.

Other marks are sometimes used—the exclamation mark (!), for instance, or Q. R. (*quantum rectum*). These are not so distinctive as underscoring, and are open to the objection that in handwriting, which is very apt to be defec-

tive, they are likely to puzzle or mislead the pharmacist by being mistaken for some other parts of the prescription. A heavy black line under the unusual dose cannot be mistaken.

A very useful book upon pharmaceutical Latin, and one which is highly recommended to the student of pharmacy is Sturmer's Pharmaceutical Latin. The following Latin prescription from Whitla's Elements, with the grammatical analysis, is so thoroughly illustrative that it is inserted almost in its entirety:

℞		Superscription
(Basis)	*Pot. Acet.* ℥ v.	Inscription
(Adjuvant)	*Tinct. Digitalis* f ℥ i.	
(Corrective)	*Syr. Aurantii* f ℥ i.	
(Vehicle)	*Decoct. Scoparii ad* f ℥ viii.	
M., ft. mist.		Subscription
Cpt. cochl. mag. ii. 4ta q.q. hora ex paul. aquæ...		Signa

Without abbreviations or contractions it would read thus:

Recipe
Potassii Acetatis drachmas quinque.
Tincturæ Digitalis drachmam unam.
Syrupi Aurantii unciam unam.
Decocti Scoparii ad uncias octo.

Misce, fiat mistura. Capiat cochlearia duo magna quanta quaque hora ex paululo aquæ.

The student will obtain needful information from a careful study of the following page, in which the Latin of the above prescription is arranged according to the English idiom, and each word parsed and translated.

Recipe Potassii Acetatis drachmas quinque

℞ (Recipe)	v.irr. tr. imp. m. 2d per. s., to agree with its nom. Tu—"thou" (understood). Recipi-o, recepi, receptum, recipere. From re and capio.	Take thou
v (quinque)	num. adj. indec. ac. pl. qual. and agreeing with drachmas	five
℥ (drachmas)	n. f. ac. pl. drachma, -æ	drachms.
Acet. (acetatis)	n. f. gen. s. qual. drachmas. Acetas, -atis.	of acetate
Pot. (potassii)	n. f. gen. s. qual. acetatis. Potassium, -ii.	of potash

Recipe Digitalis Tincturæ drachmam unam

℞ (Recipe)	(understood).	Take thou
i (unam)	num. adj. ac. s. qual. and agreeing with drachmam. Unus, -a, -um.	one
f ℥ (drachmam)	n. f. ac. s. gov. by recipe. Drachma, -æ.	drachm
Tinct. (tinctura)	n. f. gen. s. qual. drachmam. Tinctura, -æ.	of the tincture
Digit. (digitalis)	n. f. gen. s. qual. tincturæ. Digitalis, -is.	of digitalis

Recipe Aurantii Syrupi unciam unam

℞ (Recipe)	(understood).	Take thou
i (unam)	(Parsed as before.)	one
f ℥ (unciam)	n. f. ac. s. gov. by recipe. Uncia, -æ.	ounce
Syr. (syrupi)	n. m. gen. s. qual. unciam. Syrupus, -i.	of syrup
Aur. (aurantii)	n. neut. gen. s. qual. syrupi. Aurantium, -ii.	of orange peel

Recipe Decocti Scoparii ad uncias octo

℞ (Recipe)	(understood.)	Take thou
ad.	prep. used adverbially.	up to
viij (octo)	num. adj. indec. qual. uncias.	eight
f ℥ (uncias)	n. f. ac. pl. gov. by recipe. Uncia, -æ.	ounces
Decoct.[1] (decocti)	n. neut. gen. s. qual. uncias. Decoctum, -i.	of the decoction
Scop. (scoparii)	n. mas. gen. s. qual. decocti. Scoparius, -ii.	of broom

[1]Some authorities would put Decoct. in the accusative, governed by recipe. In the same way, where the student meets Aquæ ad f ℥ in the different prescriptions and formulæ throughout this work, he may substitute Aquam ad f ℥; but this latter is by no means so idiomatic as Aquæ ad f ℥.

Misce, fiat mistura

M. (misce)	v. trans. imp. m. p. t., agreeing with and governed by Tu (understood). Misceo, -ui, mixtum or mistum, miscere.	Mix you, or mix
Mist. (mistura)	n. f. nom. s. governing fiat. Mistura, -æ	Let the mixture
Ft. (fiat)	v. used as passive of facio, pres. sub. 3d s. Used as imp. gov. by and agreeing with mistura. Fio, factus sum, fieri; to be made or become.	be made

Capiat cochlearia duo magna quarta quaque hora ex paululo aquæ

Cpt. (capiat)	irr. v. tr. sub. m. pr. t. 3d per. s., agreeing with and gov. by Is—"he" (understood). Capio, cepi, captum, capere, the present subjunctive used as an imperative.	He may take, or let him take
ii (duo)	num. adj. ac. pl. neut. qual. and agreeing with cochlearia. Duo, -æ, -o.	two
Mag. (magna)	adj. ac. pl. neut. qual. and agreeing with cochlearia. Magnus, -a, -um.	large
Coch. (cochlearia)	n. ac. pl. neut., gov. by capiat. Cochleare, -is.	tablespoonfuls
q.q. (quaque)	pron. indef. abl. s., qualifying and agreeing with hora. Quisque, quæque, quoque.	at each
4ta (quarta)	num. adj. abl. s., qualifying and agreeing with hora. Quartus, -a, -um.	fourth
Horâ	n. f. abl. s. Hora, -æ.	hour
Ex.	prep.	out of
Paul. (paululo)	adj. abl. s. Used as a noun, gov. by ex. paululus, -a, -um.	a little
Aq. (Aquæ)	n. f. gen. s. qual. paululo. Aqua, -æ.	of water

A number of Latin prescriptions will be found below, the first ten of which are printed without abbreviations; it is very unusual to receive prescriptions of this kind, nevertheless their translation and study will furnish useful information.

Translate the following prescriptions, and also the accompanying directions:

1. Recipe Liquoris Ammonii Acetatis, drachmas tres cum semisse;
Vini Antimonii, drachmas duas;
Tincturæ Cardamomi Compositæ, drachmas tres;
Aquæ Menthæ Piperitæ, uncias quatuor.

Fiat mistura, cujus unciæ duæ omni horæ quadrante calefactæ summendæ, durante frigore.

2. Recipe Rosæ Gallicæ, unciam dimidiam;
Aquæ ferventis, uncias octo.

Stent per horam; colaturæ adde Succi Limonum, Sacchari, ana, quantum sufficit, ad gratam acerbitatem dulcedinemque.

3. Recipe Extracti Colocynthidis Compositi, drachmam unam;
Scammonii pulveris, scrupulum unum;
Gambogiæ pulveris, grana quinque.

Misce.—Fiant pilulæ viginti, quarum duæ deglutiantur horâ decubitûs; diluculô, ut infra.

4. Recipe Infusi Sennæ, unciam unam.

5. Recipe Potassii et Sodii Tartratis, sesquidrachmam;
Cretæ Præparatæ, semidrachmam;
Misce.—Fiat pulvis in jusculo tenuissimo sumendus.

6. Recipe Ammonii Carbonatis, grana sex;
Syrupi Aurantii, drachmas duas;
Aquæ, drachmas decem.

Misce.—Fiat haustus, cui, tempore capiendi, adde Succi Limonis recentis cochleare medium unum, et in effervescentiâ sumatur.

7. Recipe Tincturæ Opii, semidrachmam;
Spiritûs Chloroformi, drachmam;
Misturæ Cretæ,
Aquæ Menthæ Piperitæ, ana, uncias tres.

Misce.—Fiat mistura, cujus sumantur cochlearia duo magna post unamquamque sedem mollem, phialâ prius concussâ.

8. Recipe Misturæ Ammoniaci, uncias sex;
Tincturæ Opii, drachmam.
Misce.—Capiat cochlearia duo magna statim; iterentur post horam, si tussis accreverit.

9. Recipe Fluidextracti Belladonnæ, drachmam cum semisse;
Lini Farinæ, uncias duodecim;
Aquæ bullientis, quantum sufficit ut fiat cataplasma admovendum calidè loco adfecto.

10. Recipe Cetrariæ, unciam;
Aquæ frigidæ, octarium.
Coque ad uncias duodenas; stet ut geletur, et utatur æger gelatinô ad libitum.

11. ℞ Magnes. Carb., ʒi;
Pulv. Rhei, gr. xv;
Aq. Anisi, fʒiss.
M.—Fiat julep.[1] cujus unum cochl.[2] minim.[3] infant.[4] lacten.[5] detur, secundis horis: phiala agitata.

12. ℞ Sp. Ammon. Arom., fʒi;
Tinct. Asafœt., fʒss;
Syrupi, fʒiii;
Aq. Cinnam., fʒi.
M.—Exhibe cochl. parv. ter quaterve de die, vel sæpius, urgente convuls.[6] vel spasm[7].

13. ℞ Tinct. Hyoscyami, fʒiss;
Pot. Acet., ʒiv;
Syr., fʒii;
Aq. Menth. Vir., adfʒvi.
Ft. mist. cujus sumant.[8] cochl.[9] ii vel iii minim.[10] bis terve in die, vel ut opus sit.

14. ℞ Tinct. Opii, fʒss;
Mist. Cret., fʒiii.
M.—Cap. cochl. ii magn.[11] omni quadrante horæ, donec leniat.[12] dolor.

15. ℞ Pulv. Ipecac., ʒiss;
Pot. Bitart., ʒi;
Aq. fervent., fʒiiiss.
Macera per horam integr.[13] dein cola et adjice syr., fʒss.
M.—Detur fʒss vel cochl.[14] ampl.[15] omni semihorâ, donec vomit.[16] proritav.[17]

16. ℞ Plumbi Acet., gr. iv;
Syrup., fʒii;
Aq. Menth., fʒii.
M.—Cap. cochl. ampl.[18] mane quotidie; repetat.[19] dosis ad iii vices, et deinde cap.[20] æger haust.[21] aliq.[22] purgant.[23]

17. ℞ Mist. Ammon.,[24] fʒvi;
Cap. æger cochl. mag. bis in die ex poculo jusc.[25] bov.[26]

18. ℞ Morph. Acet., gr. ¼;
P. Colch.,[27] gr. iii.
Ft. pil. 4tis[28] horis s.[29]
Mitte vi fol.[30] arg.[31] inv.[32]

19. ℞ Sodii Bicarb., ʒiii;
Ammon. Bicarb., ℈ii;
Pot. Nit., ʒss;
Syr. Aurant., fʒss;
Ac. Hydrocyan. dil., gtt. xx;
Aquæ, ad fʒviii.
M.—Capiat ʒiss t. in d. cum pulv. i seq.[33] m.[34] stat.[35] effervesce.[36]

20. ℞ Ac. Tart., ℈ i;
Mitte chart. vi.

---

[1] Julepum. [2] Cochleare. [3] Minimum. [4] Infantulo. [5] Lactenti. [6] Convulsione. [7] Spasmo. [8] Sumantur. [9] Cochlearia. [10] Minima. [11] Magna. [12] Leniatur. [13] Integram. [14] Cochleare. [15] Amplum. [16] Vomitum. [17] Proritaverit. [18] Amplum. [19] Repetatur. [20] Capiat. [21] Haustum [22] Aliquem. [23] Purgantem. [24] Ammoniaci. [25] Jusculi. [26] Bovini. [27] Colchici. Tinct. Calumb.,
Syr. Zingib., āā f℥i;
Aq. Cinnam., q. s. ut ft. f℥viii.
M.—Ft. mist.

METRIC PRESCRIPTIONS

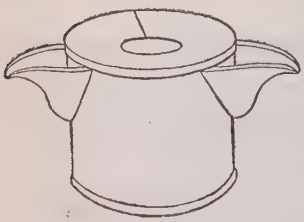
The growth of the metric system has made it necessary for every pharmacist to be acquainted with the methods employed in writing metric prescriptions.

There are two distinct methods employed in this country, which may be termed respectively the *gravimetric* and the *volumetric* method.

1. **Gravimetric Prescriptions**—The gravimetric principle of weighing liquids is used in Germany and some other Continental countries almost exclusively. It was adopted by the United States Pharmacopœia of 1880, and given the name of "parts by weight"; but, although weighing liquids may be practiced with advantage in the laboratory in making large quantities of preparations, and is preferable in the case of thick or adhesive liquids, it is far less convenient in compounding prescriptions than the plan of measuring the liquid ingredients. The advantage in supposed greater accuracy of weighing over measuring is more imaginary than real. A careful pharmacist will compound prescriptions just as accurately by measuring the liquids as he will by weighing them, while a slovenly one will be just as careless in using weights as he is in measuring liquids. The question of accuracy becomes then, practically, a "personal equation".

Several conveniences have been proposed in weighing liquids, which deserve notice. The Germans use a "tare can" (see Fig. 549) for the purpose of quickly taring a bottle. It is a small metallic can having a shallow funnel mouthed opening, with two spouts, one on each side. The bottle, or vessel, is placed on one of the scale pans, and the tare can, containing sufficient shot or clean dry sand to balance it, is placed upon the other. It is better, however, to use two tare cans and pour from one to the other, the one not in use on the scale pan either receiving the excess of shot or supplying the deficiency. Water in a bottle also serves very satisfactorily as a tare as the exact weight may be readily adjusted.

Fig. 549



Tare can

2. **Volumetric Prescriptions**—In these the gram is replaced by the cubic centimeter. The principal reason for preferring the volumetric method is that the physician has the means of more readily calculating and apportioning the number of doses in the prescription. *Liquid medicines are never administered by weight*, but always by teaspoonfuls, tablespoonfuls, or other convenient measure. In some liquids there is a wide difference between their weight and their volume, as specific gravity tables abundantly show. A teaspoonful of ether weighs forty-one grains, while a teaspoonful of chloroform weighs eighty-five grains (more than twice as much). Hence the physician cannot disregard specific gravity. In prescribing gravimetrically and administering

[1] Sumatur. [2] Amplum. [3] Augendum. [4] Cum. [5] Sequentis. [6] Amplo.

volumetrically he must constantly bear in mind these differences, at least approximately. Mistakes are very likely to arise in making these calculations, mentally, at the bedside of a patient. Hence it is far better to avoid them by *prescribing the medicines by the same method as that by which they are dispensed and administered, namely, volumetrically,* thus preserving that harmony of relation which is conducive to safety. If volumetric analysis is preferred to gravimetric analysis in the United States Pharmacopœia because of its greater convenience and at least equal accuracy, why should not liquids be measured rather than weighed in pharmaceutical operations in which extreme accuracy is comparatively of less importance?

The following examples illustrate the forms of metric prescriptions most frequently used. Form A is preferable, for the reasons stated:

Form A

℞ (*Volumetric*)
Gm. and cc.

Quininæ Sulph 1	
Strych. Sulph.	016
Fluidext. Glycyr. 4	
Syrupi 60	

A teaspoonful three times a day.

℞ (*Gravimetric*)

Hydrarg. Clor. Mit. .	5
Aloe. Pulv. 2	
Rhei Pulv. 1	5

Make twenty pills.

The advantages of the decimal line are that the decimal dot is abolished, with its dangerous complications, for a spot or a fly speck on the prescription paper may increase or decrease the quantity of an ingredient *ten times,* and the use of the decimal line is familiar to all who use a dollar and cents column.

Form B

℞ (*Gravimetric*)

Quininæ Sulph. . . . . 1.	
Strych. Sulph.	.016
Fluidext. Glycyr. . . . 4.	
Syrupi . . . . . 60.	

A teaspoonful three times a day.

℞ (*Gravimetric*)

Hydrarg. Chlor. Mit..	.5
Aloe. Pulv.	2.
Rhei Pulv.	1.5

Make twenty pills.

This form is used frequently, because of the familiarity with the arithmetical method of using a dot to denote a decimal fraction; and where metric prescriptions are altogether in use, as in Continental Europe, there is no necessity for indicating the denomination, gram being always understood.

Form C

℞ (*Volumetric*)

Quininæ Sulph. . .	1. Gm.
Strych. Sulph. . .	.016 Gm.
Fluidext. Glycyr.	4. cc.
Syrupi	60. cc.

A teaspoonful three times a day.

℞ (*Gravimetric*)

Hydrarg. Chlor. Mit.	.5 Gm.
Aloe. Pulv.	2. Gm.
Rhei Pulv.	1.5 Gm.

Make twenty pills.

This form is an improvement on Form B, and would be far superior to it for use in this country, where prescriptions written in the old systems will long continue to be used; for the indication of the unusual quantity by underscoring will prevent its being mistaken for *grain.*

Abbreviations are necessary in writing prescriptions, and they are universally employed. Great care must be taken, however, to avoid ambiguities which may mean *death to the patient.* Usually, the careful pharmacist gathers from the directions and the quantities the information which guides him safely. A few examples of defective abbreviations are appended:

Acid. Hydroc.	May mean Acidum Hydrochloricum or Acidum Hydrocyanicum
Aconit.	Aconitina Aconiti Radix Aconiti Folia
Ammon.	Ammonia (alkali) Ammoniac (gum resin)
Aq. Chlor.	Aqua Chlori Aqua Chloroformi
Aq. Fontis.	May often be read Aqua Fortis
Bar. Sulph.	Barium Sulphate Barium Sulphide Barium Sulphite
Calc. Chlor.	Calcium Chloride Chlorinated Lime
Chlor.	Chlorine Chloroform Chloral
Ext. Col.	Extractum Colchici Extractum Colocynthidis
Hyd. Chlor.	Calomel Corrosive Sublimate Hydrated Chloral
Hydr.	Hydrargyrum (mercury) Hydras (hydrate) Hydriodas (hydriodate) Hydrochloras hydrochlorate Hydrocyanas (hydrocyanate)

Hydr. Perox.	Hydrogen Peroxide Hydrargyri Peroxidum
Mist. Ammon.	Ammonia Mixture Mixture of Ammoniac (gum resin)
Potass. Hyd.	Potassium Hydrate (caustic potassa) Potassium Hydriodate (potassium iodide)
Sod. Hypo.	Sodium Hyposulphite Sodium Hypophosphite
Sod. Sulph.	Sodium Sulphate Sodium Sulphite Sodium Sulphide
Sulph.	Sulphur Sulphide Sulphate Sulphite
Zinc. Phosph.	Zinc Phosphate Zinc Phosphide

The above list might be indefinitely prolonged. Sufficient has been clearly shown, however, to convince even the most skeptical practitioner of the grave danger of careless abbreviations. The Pharmacopœia has adopted the abbreviation "sulph." for "sulphate" and suggests that no abbreviation be used for sulphur, sulphite, and sulphide. "Chlor." has also been adopted officially to mean "chloride" and chlorate is not to be abbreviated.

The Pharmacopœia also calls especial attention to the title "Barii Sulphas" which should never be abbreviated. This is to avoid any misunderstanding and the possible dispensing of the poisonous *barium sulphide* or *barium sulphite*.

The following table of abbreviations, terms, etc., used in prescriptions will be of service to the pharmacist, by enabling him to translate some of the technical phrases used in writing prescriptions:

Word or Phrase	Contraction	Meaning	Word or Phrase	Contraction	Meaning
A, āā	.....	Of each	Biduum	.....	Two days
Accuratissime	Accuratiss.	Most carefully	Bis	.....	Twice
Ad	Ad	To, up to	Bis in die	Bis in d.	Twice a day
Adde, addantur, addentum, addendo	Add.	Add, or let them be added, to be added, by adding	Bis in dies	Bis in d.	Twice a day
			Bolus	Bol.	A large pill
			Bonus	.....	Good
Ad libitum	Ad lib.	At pleasure	Brevis	.....	Short
Admove, admoveatur, admoveantur	Admov.	Apply, let it be applied, let them be applied	Bulliat, bulliant	Bull.	Let boil
			Calefactus	.....	Warmed
			Capiat	Cap.	Let him (or her) take
Ad partes dolentes	Ad part. dolent.	To the painful parts	Capsulæ amylaceæ	.....	Starch capsules,—*i. e.*, cachets
Ad tertiam vicem	.....	For three times			
Adversum	Adv.	Against	Carbasus	Carbas.	Lint, linen
Agita	Agit.	Shake, stir	Caute	.....	Cautiously
Albus	Alb.	White	Charta	Chart.	Paper
Alcoholizatus	.....	Alcoholized, finely powdered	Charta cerata	Chart. cerat.	Waxed paper
			Chartula	.....	Small paper
Aliquot	.....	Some, a few	Cibus	.....	Food
Alter	.....	The other	Cito dispensetur	Cito disp.	Dispense quickly
Alternis horis	.....	Every other hour	Cochlear or cochleare, Cochleatim	Coch., Cochleat.	A spoonful, by spoonfuls
Alvo adstricta	Alv. adst.	The bowels being confined			
Amplus	.....	Large	Cochleare amplum	Coch. amp.	A tablespoonful
Ana	A., āā	Of each			
Ante cibum	a. c.	Before meals	Cochleare magnum	Coch. mag.	A large spoonful (about half an ounce)
Aqua aërata	Aq. aërat.	Carbonated water			
Aqua astricta	Aq. astr.	Frozen water			
Aqua bulliens	Aq. bull.	Boiling water	Cochleare medium or modicum	Coch. med.	A dessertspoonful (about two fluidrachms)
Aqua communis	Aq. comm.	Common water			
Aqua fervens	Aq. ferv.	Hot water			
Aqua fluviatilis	Aq. fluv.	River water	Cochleare parvum	Coch. parv.	A teaspoonful (about one fluidrachm)
Aqua fontalis (or fontis or fontana)	Aq. font.	Spring water			
			Cola	Col.	Strain
Aqua marina	Aq. mar.	Sea water	Colatus	Colat.	Strained
Aqua nivalis	Aq. niv.	Snow water	Colentur	Colent.	Let them be strained
Aqua pluviatilis (or pluvialis)	Aq. pluv.	Rain water			
			Coletur	Colet.	Let it be strained
Aut	.....	Or	Collunarium	.....	A nose wash
Baccillum	.....	A bougie	Collutorium	Collut.	A mouth wash
Balneum arenæ	B. A.	Sand bath	Collyrium	Collyr., Coll.	An eye wash
Balneum mariæ or maris	B. M.	A salt water bath	Coloretur	.....	Let it be colored
			Commisce	.....	Mix together
Balneum vaporosum or vaporis	B. V.	A vapor bath	Compositus	Comp.	Compounded
			Confectio	Conf.	Confection
Barbadensis	B.B., B.B.S.	Barbadoes	Confricamentum	.....	A liniment
Bene	.....	Well	Congius	Cogn.	A gallon
Bibe	Bib.	Drink	Conserva	Cons.	A conserve; also to keep (thou)

Word or Phrase	Contraction	Meaning
Consperge	Consperg.	To dust or sprinkle
Continuantur remedia	Cont. rem.	Let the medicines be continued
Contra	.....	Against
Contusus	.....	Bruised
Cor, cordis	.....	The heart
Cortex	Cort.	The bark
Cotula	.....	A measure
Cujus, Cujuslibet	Cuj.	Of which, of any
Cum	C.	With
Da, detur	D., det.	Give, let be given
De	.....	Of, or from
Deaurentur pilulæ	Deaur. pil.	Let the pills be gilded
Debita spissitudo	Deb. spiss.	A proper consistence
Decanta	Dec.	Pour off
Decem, Decimus	.....	Ten, the tenth
De die in diem	De d. in d.	From day to day
Deglutiatur	Deglut.	May or let be swallowed
Dein	.....	Thereupon
Dentur tales doses No. iv	D. t. d. No. iv	Let four such doses be given
Detur in duplo	.....	Let twice as much be given
Dexter, Dextra	.....	The right
Diebus alternis	Dieb. alt.	Every other day
Diebus tertiis	Dieb. tert.	Every third day
Digere	.....	Digest
Dilue, Dilutus	Dil.	Dilute (thou), diluted
Dimidius	Dim.	One-half
Directione propria	D. P. or direc. prop.	With a proper direction
Dividatur in partes æquales	D. in p. æq.	Let it be divided into equal parts
Dividendus, -a, -um	.....	To be divided
Donec	.....	Until
Eadem (fem.)	.....	The same
Ejusdem	Ejusd.	Of the same
Electuarium	Elect.	An electuary
Emulgens	.....	An emulsifying agent
Enema	En.	An enema, a clyster
Enemata	.....	Clysters
Epistomium	Epistom.	A stopper
Et	.....	And
Etiam	.....	Also, besides
Ex or E	E.	From, one of
Ex modo prescripto	E. m. p.	After the manner prescribed, as directed
Extende	Ext.	Spread
Fac, Fiat, Fiant	F., Ft.	Make, let it be made, let them be made
Fac pilulas duodecim	F. pil. xii	Make 12 pills
Farina	.....	Flour
Febris	.....	Fever
Fervens	Ferv.	Boiling
Fiant chartulæ xii	Ft. chart. xii	Let 12 powders be made
Fiant pilulæ xii	Ft. pil. xii	Let 12 pills be made
Fiant pulveres xii	Ft. pulv. xii	Let 12 powders be made
Fiant suppositoria iv	Ft. suppos. iv	Let 4 suppositories be made
Fiat cataplasma	Ft. cataplasm.	Let a poultice be made
Fiat ceratum	Ft. cerat.	Let a cerate be made
Fiat collyrium	Ft. collyr.	Let an eye wash be made
Fiat confectio	Ft. confec.	Let a confection be made
Fiat electuarium	Ft. elect.	Let an electuary be made
Fiat emplastrum 6 × 4	Ft. emp. 6 × 4	Let a plaster 6 by 4 inches be made
Fiat emplastrum epispasticum	Ft. emp. epispast.	Let a blister be made
Fiat emplastrum vesicatorium	Ft. emp. vesicat.	Let a blister be made
Fiat emulsio	Ft. emuls.	Let an emulsion be made
Fiat enema	Ft. enema.	Let an injection be made (for rectum)
Fiat gargarisma	Ft. garg.	Let a gargle be made
Fiat haustus	Ft. haust.	Let a draught be made
Fiat infusum	Ft. infus.	Let an infusion be made
Fiat injectio	Ft. injec.	Let an injection be made (for urethra)
Fiat lege artis	F. L. A.	Let it be made by the rules of art.
Fiat linimentum	Ft. linim.	Let a liniment be made
Fiat massa	Ft. massa	Let a mass be made
Fiat massa et divide in pilulas xii	Ft. mas. div. in. pil. xii	Let 12 pills be made
Fiat massa in pilulas xii dividenda	Ft. mas. div. in. pil. xii	Let 12 pills be made
Fiat massa in trochiscos xl dividenda	Ft. mas. in troch. xl. div.	Let 40 lozenges be made
Fiat mistura	Ft. mist.	Let a mixture be made
Fiat pulvis	Ft. pulv.	Let a powder be made
Fiat pulvis et divide in chartulas xii	Ft. pulv. et. div. in char. xii	Let 12 powders be made
Fiat pulvis in chartulas xii dividenda	.....	Let 12 powders be made
Fiat secundum artis regulas	F. S. A. R.	Let it be made according to the rules of art
Fiat solutio	Ft. solut.	Let a solution be made
Fiat suppositorium	Ft. suppos.	Let a suppository be made
Fiat trochisci xxiv	Ft. troch. xxiv	Let 24 lozenges be made
Fiat unguentum	Ft. ung.	Let an ointment be made
Filtra	.....	Filter (thou)
Fistula armata	.....	A syringe fitted for use
Flavus	Flav.	Yellow
Folium	Fol.	A leaf
Fuerit	.....	Shall have been
Gargarisma	Garg.	A gargle
Gradatim	.....	By degrees, gradually
Grana sex pondere	.....	Six grains by weight
Granum, Grana	.....	Grain, grains
Gratus	.....	Pleasant
Grossus	.....	Large, coarse
Gutta	Gtt.	A drop
Guttæ	Gtt.	Drops
Guttatim	Guttat.	By drops
Haustus	Haust.	A draught
Herba	.....	A herb
Hic, Hæc, Hoc	.....	This
Hirudo	.....	A leech
Hora	H.	An hour
Hora decubitus	H. D.	At the hour of going to bed
Horæ unius spatio	Hor. un. spatio	At the expiration of an hour
Hora somni	H. S. or Hor. som.	Just before going to sleep, or on retiring to rest
Horis intermediis	Hor. interm.	In the intermediate hours
Idem	.....	The same
Identidem	.....	Repeatedly
Inde	.....	Therefrom
In dies	In d.	From day to day, daily
Ingerendo capsulas	.....	Put in capsules

Word or Phrase	Contraction	Meaning
In impetu effervescentiæ	.....	In the height of effervescence
Injectio	.....	An injection
Injiciatur enema	.....	Let an injection or clyster be given
In lagena bene obturata	.....	In a well-stoppered bottle
Inter	.....	Between
Involve gelatina	.....	Coat with gelatin
Ita	.....	In such manner
Jam	.....	Now
Lac	.....	Milk
Lamella	.....	Leaf or scale
Laridum	.....	Lard
Leniter terendo	.....	By rubbing gently
Leviter	.....	Lightly
Magnus	Mag.	Large
Massa, Massa pilularis	.....	A mass, a pill mass
Mica panis	Mic. pan.	Crumb of bread
Minimum	M. or Min.	A minim
Minutum	.....	A minute
Misce	M.	Mix
Mitte, Mittatur, Mittantur	.....	Send, let it be sent, let them be sent
Mitte talis	.....	Send of such or this
Modicus	.....	Middle-sized
Modo præscripto	Mod. præsc.	In the manner prescribed
More dictu, More solito	More dict., More sol.	In the manner directed, in the usual manner
Mortarium	.....	A mortar
Necnon	.....	Also
Ne tradas sine nummo	Ne. tr. s. num.	Do not deliver it unless paid. (Used by apothecaries as a caution to the assistant when the presence of the patient prevents the master from giving a verbal direction)
Nisi	.....	Unless
Non	.....	Not
Non repetatur	Non. rep.	Do not repeat
Nox, noctis	.....	Night
Numerus	No.	Number
Nunc	.....	Now
Nux Moschata	.....	A nutmeg
Obduce	.....	Cover, conceal, or coat
Octarius	O.	A pint
Octavus	.....	Eighth
Octo	.....	Eight
Oculus	.....	The eye
Oleum olivæ optimum	O. O. O.	Best olive oil
Omni hora, Omni bihorio, Omni quadrante horæ	Omn. hor., Omn. bih., Omn. quadr. hor.	Every hour, every two hours, every quarter of an hour
Omni mane	.....	Every morning
Omni nocte	.....	Every night
Ovum	.....	An egg
Panis	.....	Bread
Pars, partis	.....	A part
Partes æquales	P. æ.	Equal parts
Partitis vicibus	Part. vic.	In divided doses
Parvulus	.....	An infant
Parvus	.....	Little
Pastillus, Pastillum	.....	A little ball of paste, to take like a lozenge, etc.
Pectus	.....	The breast
Pediluvium	.....	A foot bath
Per	.....	Through, by
Perinde	.....	In the same manner as before
Pes	.....	The foot
Phiala prius agitata	P. P. A.	The bottle having been first shaken
Pilula	.....	A pill
Pilus	.....	The hair
Pinguis	.....	Fat, grease
Placebo	.....	To please, satisfy
Poculum, Pocillum	Pocul., Pocill.	A cup, a little cup
Pondere	P.	By weight
Pondus medicinale	.....	Medicinal (apothecaries') weight
Pone aurem	.....	Behind the ear
Post cibo	p. c.	After eating
Potus	.....	Drink
Prandium	Prand.	Dinner
Primo mane	.....	Very early in the morning
Primus	.....	The first
Pro	.....	For
Pro ratione ætatis	.....	According to the age of the patient
Pro re nata	P. r. n.	Occasionally
Proximo	.....	Nearest
Prius	.....	Before, former
Pulpa	.....	Pulp
Pulvis, Pulverizatus	Pulv.	A powder, powdered
Pyxis	.....	A pill box
Quam libet	.....	As much as you wish
Quantum libet, Quantum placet, Quantum vis, Quantum volueris	Q. l., Q. p., Q. v.	As much as you please
Quantum sufficiat, Quantum satis	Q. S.	As much as is sufficient
Quaque	Q. Q.	Each or every
Quaque hora	.....	Each hour
Quartus	.....	Fourth
Quater	.....	Four times
Quatuor	.....	Four
Quibus	.....	From which
Qui libet	.....	Whatever you please
Quinque	.....	Five
Quintus	.....	The fifth
Quoque	Q. Q.	Also
Quorum	Quor.	Of which
Quotidie	.....	Daily
Quoties	.....	As often as
Ratio	.....	Proportion
Recens	Rec.	Fresh
Recipe	.....	Take
Redactus in pulverem, redigatur in pulverem	Red. in pulv., redig. in pulv.	Let it be reduced to powder
Renovetur semel	.....	Renew once only
Repetatur, Repetantur	Rept.	Let it be repeated, let them be repeated
Res., rei	.....	Thing, substance, object, etc.
Residuus	.....	Remaining
Respondere	.....	To answer
Ruber	.....	Red, ruddy
Saccellatio	.....	A dry poultice
Saepis	.....	Often, frequently
Saltem	.....	At least
Scatula	Scat.	A box
Scilicet	.....	Namely
Secundum artem, Secundum naturam	S. A., S. N.	According to art, according to nature
Secundus	.....	Second
Semel	.....	Once
Semidrachma	Semidr.	Half a drachm
Semihora	Semih.	Half an hour
Semis	Ss.	A half
Septem	.....	Seven
Septimana	.....	A week
Sescuncia	.....	An ounce and a half
Sesquihora	.....	An hour and a half

Word or Phrase	Contraction	Meaning
Sex	.....	Six
Sextus	.....	Sixth
Si	.....	If
Siccus	.....	Dry, dried
Sic, Sic?	.....	So, is it so?
Signa	Sig. S.	Mark thou
Signetur nomine proprio	.....	Let it be written upon with the proper name (not a tradename)
Simul	.....	Together
Sine	.....	Without
Si opus sit	Si op. sit	If necessary
Sit	.....	Let it be
Solitus	.....	Accustomed, ordinary
Solus	.....	Alone
Solve	.....	Dissolve
Solvo, solvere, Solutus	.....	To dissolve, dissolved
Somnus	.....	Sleep
Sparadrapus	.....	A spread plaster
Spiritus vini rectificatus	S. V. R.	Rectified spirit of wine (alcohol)
Spiritus vini tenuis	.....	Proof spirit
Spiritus vinosus	.....	Ardent spirit of any strength
Spissus	.....	Dense, hard
Statim	Stat.	Immediately
Stet, Stent	St.	Let it stand, let them stand
Stillatim	.....	By drops, or in small quantities
Stilus	.....	Pencil, stick, or crayon
Stratum super stratum	S. S. S.	Layer upon layer
Subinde	.....	Frequently
Subtilis	.....	Fine, smooth, nice
Succus	.....	Juice, sap
Sumat talem	.....	Let the patient take one like this
Sume, Sumat, Sumatur, Sumantur, Sumendus	Sum.	Take (thou), let him take, let it be taken, let them be taken, to be taken
Superbibendo haustum	.....	Drinking afterwards this draught
Supra	.....	Above
Tabella (dim. of tabula, a table)	Tabel.	A lozenge
Talis	.....	Such, like this
Tandem	.....	At last, finally
Tantum	.....	So much, so many
Tegmen or Tegumen	.....	A cover
Tempus, temporis	.....	Time or temple
Tenuis	.....	Fine, thin
Ter	.....	Three times
Tere	Ter.	Rub
Ter in, or ter die	T.i.d., or t.d.	Three times a day
Tertius	.....	Third
Tres	.....	Three
Triduum	.....	Three days
Tritura	Trit.	Triturate
Tussis	.....	A cough
Ubi	.....	Where, wherever, whenever
Uncia	.....	An ounce
Unctulus	.....	Besmeared, anointed
Unguilla	.....	An ointment box
Ustus	.....	Burned
Ut dictum	Ut Dict.	As directed
Utendum	Utend.	To be used
Uto, uti	.....	To make use of
Vas Vitreum	.....	A glass vessel
Vehiculum	.....	A vehicle
Vel	.....	Or
Venenosus	.....	Poisonous, a poison
Verus	.....	True, genuine
Vesper, vesperis	Vesp.	The evening
Vitellus	.....	Yolk
Vitello ovi solutus	.....	Dissolved in the yolk of an egg
Vitreum vitrum	.....	Glass

CHAPTER XCVI

FILLING THE PRESCRIPTION

The Meaning of Professional Service—Through centuries of civilization there has been a sharp distinction between those who claim professional ideals and those who were tradesmen. Those who performed the latter functions were long considered inferior, socially, and in fact were generally believed to represent sharp business practice. In fact the legal phrase "*caveat emptor*"—"let the buyer beware"—reflects the impression of centuries concerning trade practices. It was long recognized that if the buyer was not sufficiently clever or shrewd and was beaten in a trade or deal that it was legitimate and the reverse situation was equally accepted. The object of trade is primarily to sell at a profit, the motive being wholly selfish. On the other hand, professional service depended upon the underlying principle of service to humanity, without thought of gain. The elaborate codes of ethics (see page 9), promulgated by professional savants, reflect the ideals of professionalism.

All professional service sprang from religious sources, from an innate, God-given, instinct in humanity prompting a desire to help those who are less fortunate. This was first exhibited in an effort on the part of a priest to bring to the souls of men needed comfort and hope. It soon became evident that the soul ills were often accompanied by bodily ills. Since the desire was to serve, it was natural that there should be added to the initial effort, an attempt to cure bodily sickness, and from this developed the medical profession.

Another great evil also became apparent to the priest—the injustice in the world, often responsible for much suffering. Once again from the priests emanated certain principles and laws expressing justice and right, and the legal profession was the outgrowth. Education was also one of the activities of the church for centuries.

These several professional services were rooted in the principle of service to humanity, for the good of those served and not for the gain of the doer, and was an expression of the finest instincts of the human heart.

Pharmacy finds its place in the professions through its being an important medical specialty. It occupies today a place among the divisions of the medical sciences fully equal in importance to many other special divisions of medicine. This may be emphasized forcibly by considering the organization of a modern hospital.

A number of the divisions of the hospital could be closed for a week without serious inconvenience—the pathological laboratory, the X-ray division, and even the clinical laboratory, but should the pharmacy be closed for a single day the hospital would be disorganized. Its services are manifold and important in maintaining medical and sanitary supplies.

It is important at this time, since reference has been made to the traditions of trade, to refer to the development of modern business in which the older practices have been largely abandoned. Of course, they are still found under some conditions, but in the large business of today, especially in organizations conducting a national business and doing national advertising, the highest ethical ideals are taught and practiced. In fact, many phases of modern business are professional in spirit.

As an illustration of the professional service rendered by pharmacy, it is only necessary to consider the peculiar opportunities afforded the neighbor-

hood pharmacist. It is assumed, of course, that the pharmacist personally represents the best training and ideals of pharmacy. Unfortunately, many in recent years have entered the drug business without professional ideals and with no purpose other than the handling of merchandise and the gaining of profit.

The true pharmacist, however, is properly equipped and trained and possesses the confidence of physicians and of the community through his personality and ability. As an illustration of this relationship of the pharmacist to the community the following experience is cited.

In a nearby home a child is taken seriously ill. A physician is called and verifies the worst fears. It is pneumonia. Several prescriptions are written, perhaps an order given for material for an enema, an ice-cap, a hot-water bottle, a bed-pan, and a dozen other medical aids. The pharmacist is called upon to supply these various needs and he is as deeply interested as the physician in giving every service possible and makes himself available at any hour of the day or night. Perhaps a crisis arises and oxygen is needed; a telephone call and he delivers it without delay.

Now suppose one of the prescriptions had been for digitalis and this was needed in the crisis. Suppose it had been allowed to deteriorate or had not been standardized. The responsibility would have rested directly upon the pharmacist. The life of the child was at that moment dependent upon his integrity and skilful service.

This illustration is multiplied within the year by hundreds of similar responsibilities. He is consulted for advice upon a thousand matters. The training, and honesty, and tact of the pharmacist should be an important community asset and the demand for service will be in direct proportion to the willingness to serve and the ability to render needed aid. Professional pharmacy is exemplified by the daily routine of hundreds of splendid American pharmacists who receive little reward other than the gratification following professional service well done.

To further emphasize the importance of professional pharmaceutical service, reference need only be made to the production by manufacturing pharmacists of modern biologicals; the extensive researches into the field of new and modern medicine, being promoted by pharmaceutical firms, organizations, and colleges, and by the monumental service rendered the nation through the unselfish and coöperative work done by pharmacists and physicians in the preparation of the national standards, the Pharmacopœia and the National Formulary.

With this introduction and with a clear recognition of the professional services of the pharmacist, the filling of prescriptions, commonly called "*dispensing*", may be undertaken.

THE EQUIPMENT FOR DISPENSING

For the proper organization of a modern prescription department, there must be certain basic equipment. This may be divided into several groups. First, the dispenser, second, the physical equipment—fixtures and apparatus, etc., third, the stock of medicines, fourth the library, fifth the laboratory. These are taken up in order.

The Dispenser—For a proper appreciation of the prescription which is to be filled, the prescriptionist must be imbued with the fundamental principles just described which underlie professional service, and there must be a strong sense of fundamental honesty. The compounded prescription must always represent a sincere effort to supply the physician and the patient with exactly

what is intended, which involves not only proper compounding but also efficient, dependable medicines.

Little need be said about the fundamental training and personality of the prescriptionist, but it is universally conceded that there must be represented proper general education and culture and of course the technical training which is legally required for qualification as a dispenser. Practice, in addition to technical training, is necessary to develop the greatest skill and efficiency.

The Physical Equipment—The exact details of the dispensing department of the pharmacy must be left to the local conditions but there are certain basic principles which may be incorporated in every dispensing department. There must be some place in which the customer may be met. This is usually in the store proper or there may be a special reception room provided, fitted very much like a physician's office. A number of pharmacies in which professional work is emphasized, provide such facilities (see Fig. 440). The receiving of the prescription will be discussed on page 1604.

The Counter, Fixtures, etc.—*The Prescription Counter*—The prescription counter should be fitted with the more frequently used chemicals, drugs, and preparations, and close at hand should be the closet containing actively poisonous substances, and also the closet for narcotics. Provision may be made for other stocks such as less frequently used chemicals, drugs, preparations and the stock of pills, tablets, ampuls, biologicals, ointments, etc. All medicinal substances likely to be called for upon prescriptions, should be neatly and systematically stocked. For this purpose, sectional cases, made up of small drawers, are especially well adapted. Fig. 455 illustrates the Schwartz system which is extensively used. Fig. 457 shows another form of section also adapted for the systematic storage of many small items.

There should be an index on loose-leaf sheets or a card index, indicating the location of every item in the store. Biologicals and ointments should be kept in a refrigerator, the refrigerator is often given a conspicuous place in the dispensing section of the store.

The prescription counter should be kept free from merchandise or an accumulation of bottles or other packages and the lower section should be fitted with small drawers in which may be kept various sizes of clean and dry bottles, powder and pill boxes, and all other forms of containers; also corks, caps, and all of the necessary equipment for prescription filling, such as suppository molds, filtering and sifting devices, mortars and pestles, spatulas, etc.

Figs. 454 and 456 illustrate typical modern prescription counters. Fig. 458 is a prescription case made by the McLean Fixture Company. Fig. 460 is a steel prescription case, recently installed by The Wilkinson Equipment Company of Philadelphia, in the store of Frank E. Morgan, Philadelphia.

The Stock Containers—The stock containers frequently used for chemicals and powdered drugs and also those for liquids needed at the prescription counter, are small glass-stoppered, glass-labeled bottles; many stores however prefer the original bottle in which the drug or chemical was purchased, and as most of the packages are kept in closets or drawers this is often practicable. There is an added advantage for this plan, when only small quantities are bought, since it retains the identity of the manufacturer should any question arise concerning its quality. The elaborate array of glass-stoppered bottles with glass labels, so characteristically a feature of the drug stores of a few years ago, has been almost entirely replaced in the front of the store by attractive fixtures, filled with salable commodities.

In many remodeled stores these older style of bottles containing pharma-

ceuticals, chemicals, and drugs are still found in the vicinity of the prescription department.

Figs. 550 to 553 illustrate the usual types of tincture and salt-mouthed

Fig. 550

bottles for the prescription department. Glass labels are usually recessed to avoid clipping the edges or they are of the indestructible type which are painted directly upon the bottle, then glazed, and afterward burned into the glass. Several special styles are also made. Fig. 554 illustrates a syrup bottle

Fig. 554

Fig. 556

Syrup in an ordinary bottle

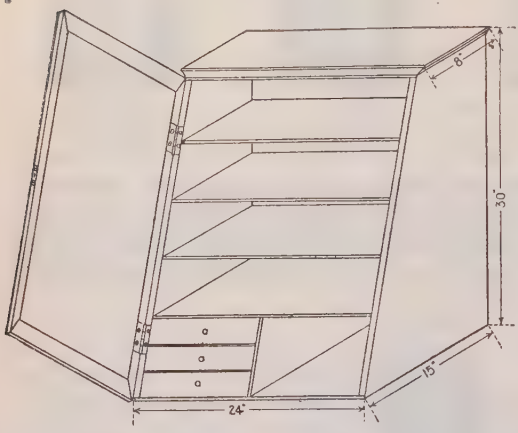
with a loose stopper while Fig. 555 is for oil. This is fitted with a lip from which the excess of oil runs back into the container. A cover keeps the dust from the entire top. Fig. 556 shows the result of using an ordinary glass-stoppered bottle for syrup.

The Sink—The ideals of the pharmacist for cleanliness and neatness are frequently exemplified by the sink in the prescription department. Needless

to say this should be arranged in accordance with the best sanitary plumbing methods and should provide both hot and cold water. A drain board and a graduate rack are important adjuncts. Fig. 461 illustrates the sink arranged with bronze fittings also recently installed in the pharmacy of Frank E. Morgan, in Philadelphia.

The question frequently arises, whether dispensing pharmacists should be expected to clean apparatus. The position usually taken is that should this be necessary it would not be refused but that it is an uneconomical management that requires the pharmacist, whose services are very costly, to perform such menial tasks. In the pharmacy of Hynson, Westcott and Dunning in Baltimore, the dispensing pharmacists are provided with an ample assortment of apparatus which is cleaned and polished. This apparatus is conspicuously placed on glass shelves near the dispensing counter. As the dispenser soils the apparatus it is placed in a small compartment in the prescription case. A woman employed for the purpose, regularly collects the soiled apparatus in a basket, carries it to the rear where adequate facilities are provided for washing and drying. The clean and dry apparatus is then returned ready for use again.

Fig. 557



Poison closet

When the prescription business is sufficiently large, the plan just suggested is undoubtedly the most satisfactory and economic.

The Poison Closet—It is the custom in most stores to keep all poisons, alkaloids, and very powerful substances in a separate closet, and to mark all bottles with a poison label, for, although the pharmacist should early learn to place no absolute dependence upon any *special system* of preventing errors, but always to realize that constant, unremitting vigilance is the only safeguard, the adoption of some expedient which will aid in calling attention to poisonous compounds serves to impress upon all, particularly the assistants, the fact that safety can be secured only at the expense of the most vigilant care. A poison case, which has given much satisfaction is illustrated above. It is about 24 inches wide by 30 inches high; 8 inches wide at top and 15 inches at the base. The three drawers, as shown in Fig. 557 are reserved for the very active poisons, while the shelves hold the less poisonous drugs. No arrangement of poisons otherwise is made so that the pharmacist has to look for the poison wanted which does much to offset any preoccupation of mind. Many of the active liquid poisons are kept in regular poison bottles with sharpened glass stoppers. The form of the case always causes the door to shut. The door should be lettered with the word "POISON" and should also carry the poison symbol, a "skull and cross bones". The door, if glass, should be painted black on the inside, which effectually excludes the light.

This is an easily constructed case and serves its purpose well.

Receiving the Prescription—Fig. 446 illustrates the front part of the store of Hynson, Westcott and Dunning, of Baltimore, which is typical of

the finest development of professional pharmacies The customer is met by someone qualified to represent the professional service offered. Frequently this particular position requires the most skilled pharmacist in the organization. There should be a dignified reception of the customer. All levity or other lack of professional manner should be absent. It should be remembered that the customer has probably come from a sick-room and is deeply concerned over the serious illness of a member of the family. The greatest possible confidence must be inspired through everything that is said and done, and the physician must be supported in his effort to give hope and faith in the treatment.

The prescription is received and read by the pharmacist and he learns whether the customer will wait or have the prescription delivered. Usually these facts are written upon a blank form kept at the counter and this is clipped to the prescription when it is turned over for compounding.

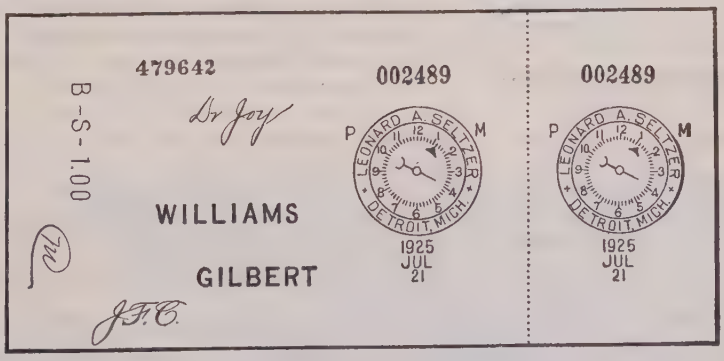
The following prescription memorandum has been used by many stores with excellent results. These blanks are put up in tablet form, and are filled in, in the presence of the customer, or the back of the prescription may be used for noting the points when it is handed in.

MEMORANDUM

Name.
Address.
Is it paid for?
Is it to be charged?
Is it to be called for?
When?
Is it to be sent?
When?
Received by
Compounded by
Number of ℞ and price

Fig. 558 illustrates a form used in the pharmacy of Leonard A. Seltzer, of Detroit. The coupon which carries a call number is handed to the waiting customer to identify the prescription when filled. On the reverse side of this

Fig. 558



Prescription memorandum form (one-half size)

coupon (see Fig. 559) is printed an interesting message which was originally written by H. P. Hynson of Baltimore, and is used by many pharmacists.

The course of a prescription in the pharmacy of Mr. Seltzer is as follows:

1. The prescription is received.
2. The clock number is stamped in duplicate on the blank and on the coupon, and, if it is a call package, the latter is then detached and handed to the waiting customer.

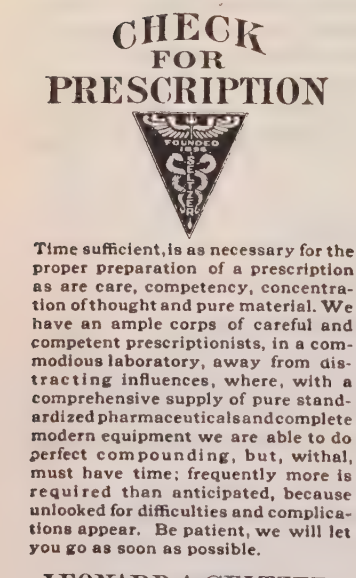
3. If it is a new prescription the number assigned to it is stamped on the blank and also on the prescription and the two are clipped together.

4. The label is now written (see Fig. 560), using the prescription number, and the clock number is also stamped on the label in red.

5. All facts are now recorded in a book ruled for the purpose, as follows:

Clock number	Doctor	Patient	Article	Clerk
002487	Brown	Jones	℞ 468474	Williams

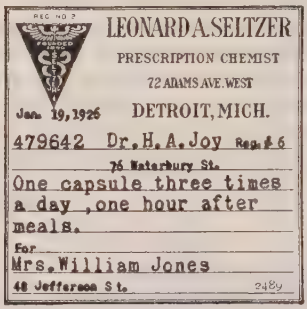
Fig. 559



CHECK
FOR
PRESCRIPTION
Time sufficient, is as necessary for the proper preparation of a prescription as are care, competency, concentration of thought and pure material. We have an ample corps of careful and competent prescriptionists, in a commodious laboratory, away from distracting influences, where, with a comprehensive supply of pure standardized pharmaceuticals and complete modern equipment we are able to do perfect compounding, but, withal, must have time; frequently more is required than anticipated, because unlooked for difficulties and complications appear. Be patient, we will let you go as soon as possible.
LEONARD A. SELTZER
60-64 ADAMS AVE. W.

Reverse side of prescription customer's coupon

Fig. 560



Prescription label

6. The compounding clerk then takes the prescription, label, etc., signs his name in the book, fills the prescription and stamps his name on the blank.

7. The dispensing clerk completes the prescription by attaching the label and checking all details of the prescription with another clerk, the latter also placing his name on the blank.

8. The dispensing clerk now wraps the package, attaches the blank to it with an elastic band and hands it out for delivery. He keeps the prescription for filing.

9. If the prescription is called for one of two things happens:

a. It is paid for and the price printed on the end of the slip by the cash register (see Fig. 537), the slip being filed.

b. If not paid for the details of the charge are written on the slip and it is filed for the bookkeeper.

10. If the prescription is to be delivered it is placed on the delivery counter and sent out as soon as a messenger is available. The name of the messenger is placed on the slip and it is placed in the cash register until he returns when he must report. If it has been paid for, the amount is rung up on the cash register which prints the amount on the slip. If it is to be charged the details are written on the slip and it is filed for the bookkeeper. The messenger also obtains a receipt for the package in his own book.

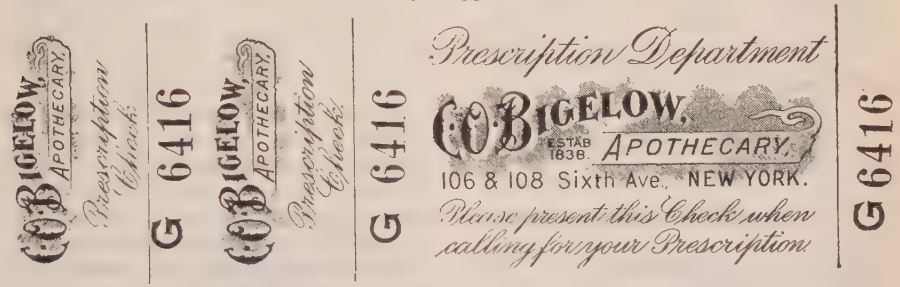
11. On the following morning a clerk files all of the prescriptions of the previous day, arranging them in numerical order and also the corresponding slips, when all can be checked and all records completed.

Fig. 561 is a form of prescription check usually printed with a triplicate

number. The large stub is held by the customer, the second stub is detached and pasted on the prescription blank, and the third number is attached to the filled prescription.

Fig. 562 is a copy of an order form used by Ambrose Hunsberger. He uses no checks or numbered coupon but prefers to use the name of the customer for the identification of the filled prescription. The order blank suggests the necessary information which should accompany every order and when placed

Fig. 561



Prescription check and stub

in the cash register or on a stick file often becomes a valuable reminder of a forgotten charge or other service connected with the order. These order forms are kept at the telephone and at other convenient places in the store and a similar form is stamped on the back of a prescription when received, becoming a permanent record.

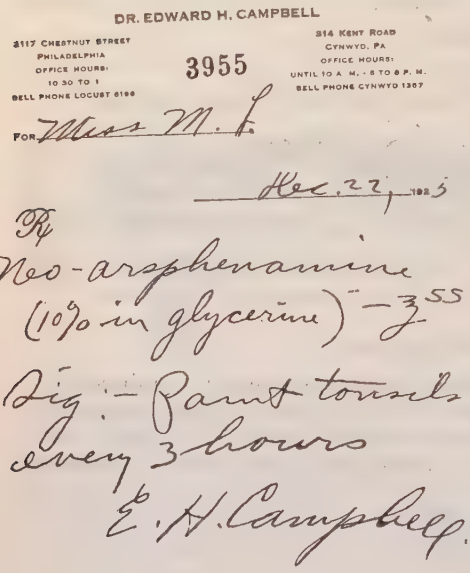
Composite order form

In rendering professional service in the community the pharmacist will constantly be called upon to fill spoken or written orders from the layman. This apparently simple matter, if not carefully considered, is frequently the source of embarrassing mistakes. Very few customers, even if they are intelligent, realize the necessity of forethought or care in calling for articles that they wish. Hence it is an excellent practice for the dispenser to *repeat the order* interrogatively at the time it is given, and obtain from the customer a clearly expressed assent before delivering the article, lest the wrong one be dispensed. If it is a poisonous substance, the use that is to be made of it should be carefully inquired into, and in all cases the sale should be entered in a regular poison book and properly dated and signed by the purchaser. Poisonous or dangerous substances should never be dispensed to children or minors without a written order, and even then the receiver should be cautioned about the contents.

Reading the Prescription—Having received the prescription it should be read over carefully, and judgment mentally pronounced, first upon the

safety of the doses of the respective ingredients, and then upon their compatibility. If this reading be done in the presence of the patient, especial care should be taken that the countenance reveal nothing whatever of what may be going on in the mind of the receiver. A shrug of the shoulders, an elevation of the eyebrows, a contemptuous toss of the scrap of paper on the prescription desk, may convey to the mind of the patient a more lasting impression of the opinion of the receiver as to the merits of the prescription than open criticism. Questions are frequently asked by patients and requests made for opinions. These should always be skilfully parried. A pharmacist has no right to reveal to a patient the character or the medicinal effect of the ingredients which enter into a prescription. When the names of the ingredients in the prescription are persistently demanded by the patient, the dispenser can fall back upon the expedient of frankly stating that it is a breach of etiquette to reveal the character of the ingredients, and intimating that it shows a lack of confidence in the prescriber on the part of the patient; but, if further insisted upon, the offer to send to the physician a written request to get his permission to disclose the ingredients is generally answered by the patient with a gracious "no matter". The pharmacist, as a co-worker with the physician in the healing art, is ethically bound to sustain him and cheerfully coöperate with him, and there should be at all times a spirit of mutual respect between the members of both professions, and a feeling that each is in duty bound to protect the other from unjust censure.

Fig. 563

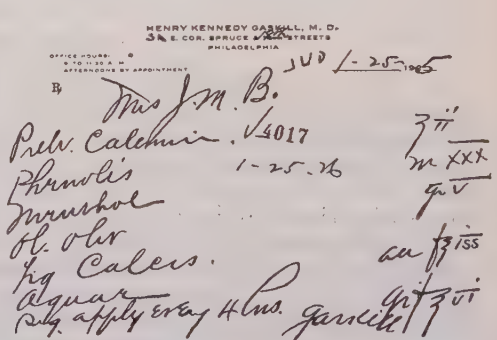


Typical modern prescription

In the majority of cases when the prescription has been received and the necessary information obtained concerning delivery, it is best to retire to the prescription department for a detailed study of the prescription.

Figs. 563 to 568 are typical modern prescriptions inserted here for practice in reading prescriptions.

Fig. 564



Typical modern prescription

Omissions and Errors—If an *obvious* error or omission in the prescription is detected by the pharmacist, or an unusually large or poisonous dose has been prescribed, it is generally easy to gain the necessary delay, upon the plea that the prescription will require considerable time to compound, or for some

other reason which will not excite the suspicions of the patient and in the meantime the physician may be consulted. The careful pharmacist will always

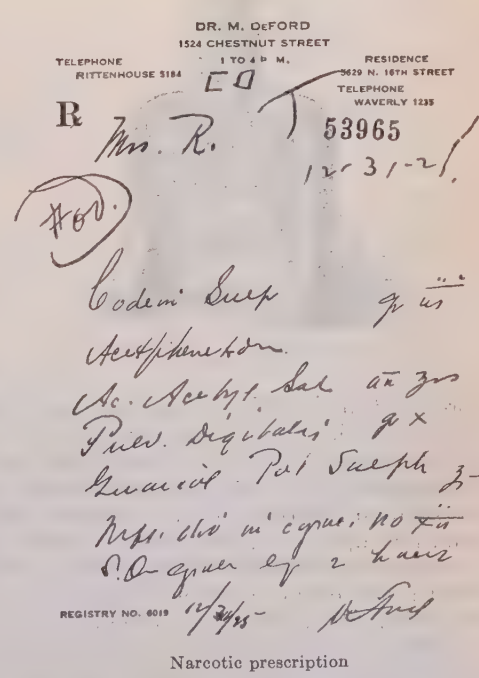
FIG. 568



Narcotic prescription

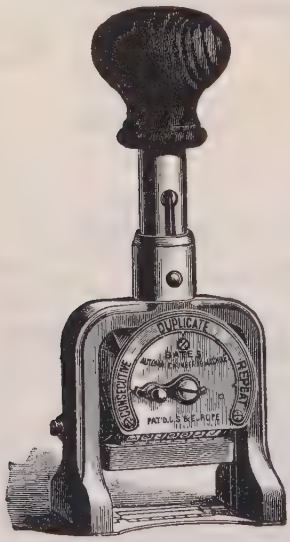
check the dose of potent remedies when prescribed and be confident that they are within reasonable limits of safety. The physician usually indicates an exceptionally large dose by underlining it so that the pharmacist may dispense

it without a question. If this has not been done it is best to consult the physician if he is within reach and in no instance should a dangerously large dose be dispensed without knowing that it is intended. Good judgment is necessary at all times, and where delay is entirely inadmissible there is nothing left for the pharmacist to do but to assume the responsibility of making the dose safe, or of supplying the omission according to his best judgment. In this case a written explanation should be sent immediately to the physician.

In the case of omissions or errors on the part of the pharmacist, so much judgment is needed which must depend upon the circumstances surrounding each case, that it would be unsafe to offer any suggestions. Generally the physician must be appealed to, and upon his skill and tact reliance must be placed. In such cases it is not often that he is found unwilling to exercise his good offices.

Additions or Alterations to Prescriptions by the Pharmacist—At the

Fig. 569



Numbering machine

Fig. 570

Rubber dating machine

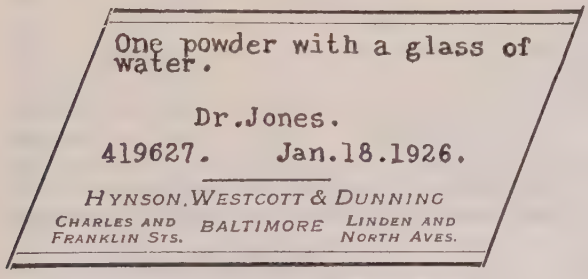
present time it is the custom among physicians to hold the pharmacist responsible for the proper compounding of prescriptions intrusted to his care, and to depend upon him. Such details as the choice of the excipient, method of straining or filtering, etc., are usually not specified. Indeed, with many it is a common practice simply to direct a solution or mixture of definite strength and rely upon the pharmacist to make it palatable. In all cases of this kind, care must be taken to make a note upon the prescription of each addition, so that in the event of renewal there may be no difference between the preparation then obtained and the original. The confidence which physicians place in pharmacists in this respect should be most sedulously guarded and every effort made to deserve and retain it. This can be done only by adhering strictly to the rule of *not permitting an alteration or addition to be made to a prescription which would affect or vitiate its proper medicinal action or interfere with the obvious intention of the prescriber.*

Numbering the Prescription—It is the universal practice to number the prescription, and to place a corresponding number upon the label, the object being to identify the bottle or package in case of renewal and connect it with the original prescription. This apparently simple matter requires, on the part of the compounder, concentration of thought to avoid errors—one of the most frequent lapses being that of duplicating the number of the last prescription, instead of numbering it consecutively. This, in case of renewal, may lead to serious consequences, especially if one prescription happens to be a four ounce aconite liniment and the other a four ounce solution of similar appearance for internal use. The duplication of the numbers is liable to occur when several prescriptions are being compounded at the same time by two or more assistants. Various expedients have been proposed to obviate mistakes of duplication. One is to simply write the numbers on a pad kept for the purpose, carefully avoiding duplication by insisting upon each number being entered before the label is written, but the better plan is to use a numbering machine.

Consecutive Numbering Machines—These are very convenient, and serve excellent purposes if they are properly and durably constructed.

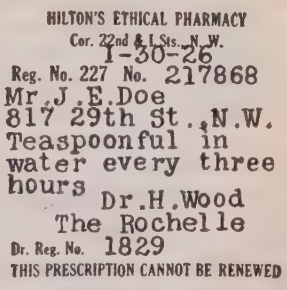
The usefulness of this machine to the pharmacist consists largely in the

Fig. 571



Prescription label for special box

Fig. 572



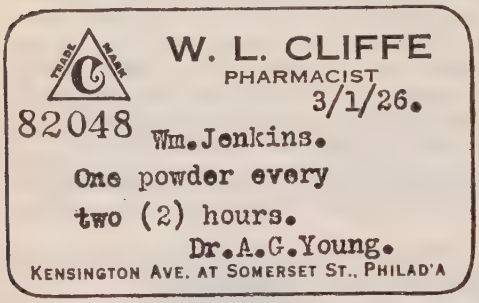
Label for narcotic prescription

fact that it can be made to *number consecutively in duplicate* (13428, 13428; 13429, 13429, etc.), so that if a proper sized machine is chosen (letter *b* is preferred) the number may be clearly and neatly printed upon *both prescription and label;* the machine may then be locked and set, so that there is not the slightest danger of variation of numbering while in use. The Bates automatic numbering machine (see Fig. 569) is believed to be the best numbering machine now available although many others are offered. It can be set so that the numbers will be consecutive, repeated indefinitely, or repeated in duplicate or triplicate as desired. The value of using a mechanical contrivance of this kind consists in its numbering in duplicate with absolute freedom from mistakes, and in the entire elimination of chances of error from defective handwriting, the figures being printed from hardened steel disks, invariably producing clear and distinct impressions. Bates numbering machines are also made which stamp the date in addition to the number.

Rubber numbering stamps are also in use; these are much cheaper and smaller than the consecutive numbering machines, and are very convenient. They are not automatic, however, and mistakes are liable to occur through the operator forgetting occasionally to turn one of the bands, and thus the main reason for using a numbering machine is lost. The numbers are cast upon endless rubber strips, and resemble the daters (see Fig. 570).

Dating—This also serves to fix the identity of a prescription, and it should never be omitted. The physician usually appends the date, but the prescription is frequently held by the patient and not presented for compounding upon the day on which it is written. As in the case of numbering, the date is most frequently written upon the face of the prescription by the pharmacist; and this should not be omitted, even though the date written by the physician be visible. The habit of dating should be firmly established, because it may prove of vital importance in case of a subsequent discussion or difference of opinion. *Rubber daters* are largely used now. Fig. 570 shows one which may be obtained from any stationer. It is inexpensive, not liable to get out of order, and so convenient for prescription work that it soon pays for itself.

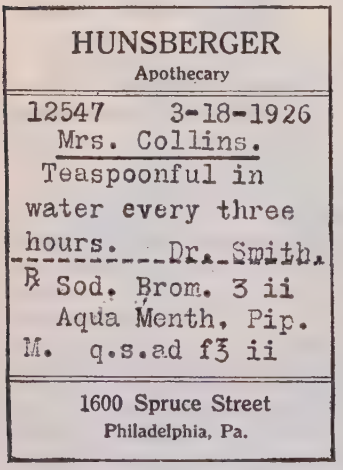
Fig. 573



Prescription label without border

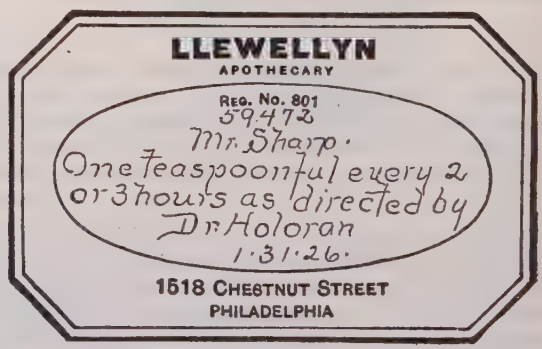
The Prescription Label—Usually the label is written first. This is an opportunity for a study of the prescription, without seeming to delay the filling. In some stores the label writing is done by a special clerk, who either writes exceptionally well or who handles the typewriter skilfully. Most modern prescription labels are typewritten on a special typewriter having a clamp for the label upon the platen of the typewriter. A typewriter for this purpose should be fitted with the smallest obtainable type, at least not larger than "elite", and should be fitted with a medical key-board

Fig. 574



Prescription label with copy

Fig. 575



Prescription label, handwritten

including the following characters: ℨ, ℥, ℈, and *M*. Many such machines are now available.

The labels for typewriting are usually without lines (see Figs. 571 to 575). They are also frequently printed without margins to avoid trimming and others are printed in strips to facilitate handling in the typewriter. Figs. 571 to 578 illustrate typical prescription labels as prepared in leading pharmacies.

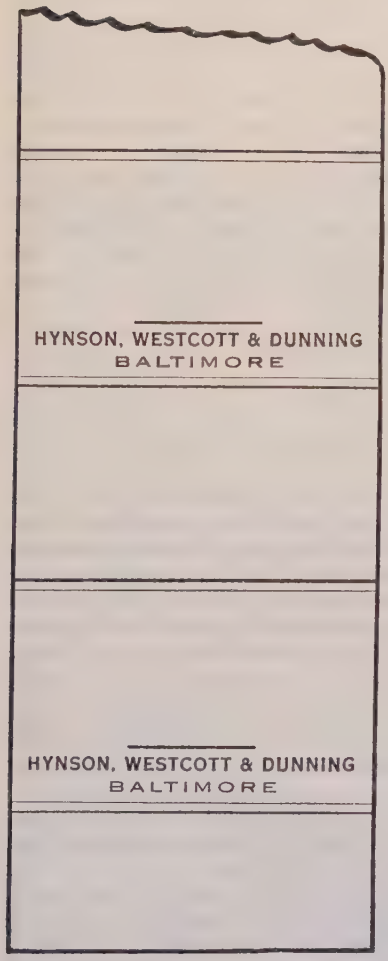
A prescription label should carry the number of the prescription, the date

of filling, the name of the patient, the directions for administration or use, and the name of the physician. Every label statement should be carefully checked to avoid error. It is of importance that the prescription label should be legible and indicate skill so that the impression upon the physician and the patient may be favorable.

When the label is attached to the finished prescription, it hardly seems necessary to suggest that it be straight, be rubbed perfectly smooth, and be without a blur or blot. The main prescription label when attached to a bottle should occupy a position slightly above the center of the bottle. If it is printed with a margin, it should be carefully trimmed with an even white line. This latter suggestion about trimming especially applies to strip labels carrying directions to "shake", "keep in cool place", or other special instructions.

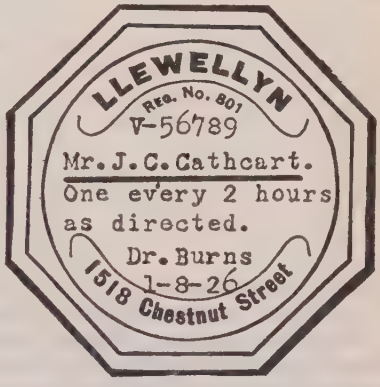
A physician frequently requests that a copy of the prescription be attached. Usually this is written or typed upon a special label, which is attached in an inconspicuous place upon the package.

Fig. 576



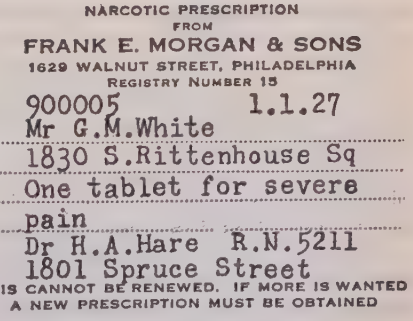
Labels in strips for typewriting

Fig. 577



Prescription label

Fig. 578



Label for narcotic prescription

Some prescription labels are arranged with an extension on the right side or are exceptionally long (see Fig. 574), providing a space upon which the copy may be typed. It is understood, of course, that in case the prescription contains a poison or a narcotic drug a copy must not be attached or given to the patient.

The Stock of Pharmaceuticals—Recognizing that the proper training of the pharmacist and the physical equipment of the dispensing laboratory are important, it must not be forgotten that the maintenance of an efficient stock of pharmaceuticals is an essential part of the service. The training of the pharmacist should qualify him to pass upon the character of the medicinal agents which he dispenses: not only identifying them, but determining their quality; in fact, the dispensing of therapeutically active and reliable medicines should rest upon the conscience of the pharmacist with such force that the selection and maintenance of stock should occupy a degree of importance only second to the accuracy of dispensing.

It is not possible today for the retail pharmacist to make certain products. This question has been discussed elsewhere. However, this does not relieve the pharmacist of the responsibility under the laws and under his conscience to select manufactured products which are dependable and to preserve and store these in such a way that they will not deteriorate. If products are known to have deteriorated they must not be dispensed. The specific action of fluidextract of ergot or a tincture of digitalis in a crisis may save the life of the patient. If the product supplied the physician does not respond as he has reason to believe it should, the responsibility or failure rests upon the pharmacist. It is oftentimes an advantage to select the line of products manufactured by a reliable firm and utilize their reputation in increasing the confidence of the physician in the prescription department.

The Compounding of the Prescription—Having written the label, the dispenser proceeds to the prescription case and assembles every ingredient required by the prescription. These are placed on the left side of the scale, or within a small frame which stands on the counter. As the ingredients are weighed or measured they are transferred to the right side of the scale or lifted from the frame. This provides a mechanical check upon the introduction of each ingredient. The prescriptionist is frequently called to the front of the store during the time of filling, and when he returns, if this policy is followed, there can be no question concerning which ingredients have been used. The prescription being properly compounded, in accordance with the skill of the dispenser, the product is transferred to a suitable container which is then labeled.

Checking Prescriptions—The prescription is now to be checked. If two pharmacists are not available, the careful re-check by the prescriptionist, of every item, should be made the routine practice of the store.

If there are two pharmacists in the store, they should always check each other on every prescription filled. This policy is primarily intended to detect an error which may have been made, but its influence is far broader inasmuch as it insures especial care on the part of the dispenser, as he will be very certain that there is no mistake before exposing himself to the possible criticism of an associate. The rule to check every prescription, therefore, usually prevents an error through the exceptional care which is exercised during the filling.

The checking of the prescription should proceed as follows: The dispenser holds the finished prescription. The one to check has before him the written prescription. The dispenser reads the label in detail and then indicates the ingredients individually, naming the quantities used.

All ingredients must still remain upon the counter, to be verified by the

one checking. Only after following this course should the prescription be released and the ingredients returned to their respective places. The custom so often practiced of reaching for a bottle of a chemical salt or a preparation, measuring or weighing the quantity, and immediately returning the bottle to its place, is reprehensible and dangerous. The momentary glance at the label is not sufficient and often more dependence is placed upon the location of the bottle than the reading of the label.

By the plan suggested the bottle must first be found and placed upon the counter. To weigh and measure the ingredient the bottle or container must again be handled, which means the reading of the label. The one who checks the prescription also sees the package and verifies the label and for the fourth time the label must be read when the container is returned to its permanent location. This quadruple check upon a label eliminates many serious errors.

A Poison—When a poisonous substance is found to be an ingredient in a prescription, there should always be extra caution as a matter of routine. The principle is exactly that involved by the added caution needed and exercised upon approaching a railroad crossing. The pharmacist should ever remember that *"eternal vigilance is the price of liberty"*.

The following routine for filling prescriptions, or slight modification of it, is in force in many drug stores:

Rules Governing Prescription Filling

NO TALKING

(Except in checking prescriptions)

1. Consider the prescription as a whole, including form, dose, incompatibilities, solubilities and method of filling.
2. Write the label.
3. Remove from the prescription case and place together on the counter on the left side, all shop bottles or containers needed in filling the prescription.
4. Compound the prescription, placing the containers of ingredients, as used, on the right side, and transfer the product to a suitable container.
5. Have the label checked by reading it off to the assistant, consider the number, date, name, directions, and doctor's name and then check the ingredients of the prescription.
6. Finish the package for delivery, capping all bottles, calculating the price, wrapping and attaching a delivery card bearing the price to be paid.
7. Return all shop bottles and containers to their proper places.

Pricing the Prescription—The price of the prescription must always be marked upon it. This is necessary in order to fix the sum in case of renewal. The price is usually not subject to variation, except in the case of a patient ordering a larger or smaller quantity of the prescription. In renewals, in all cases the increase or decrease should be noted distinctly, if future annoyance is to be avoided. Few occurrences are apt to create more distrust in the mind of the patient than a neglect of this precaution, the reasoning being that if the pharmacist is so careless as to have two prices for the same prescription, he probably has been careless in compounding it.

It is usual for the pharmacist to adopt a cipher to show the price of the prescription, some word or combination of characters being selected and memorized. If a word is selected, it should have ten letters, and there should be no duplicate letters, thus:

COME AND BUY
1234 567 890 C.YY—$1.00; OA—25 cents, etc.

The following words or phrases may be used as price marks: Behaviour, chemistry, complaints, no mistake, volumetric, duplicates, republican, democrats, epistolary. A word with nine letters requires an odd letter, usually X. Sometimes a repeater, like X, is employed; thus, in "come and buy", $1.00 would be C.YX. The cipher adopted by the National Association of Retail Druggists is largely used. It is PHARMOCIST. (See also page 1332.)

It frequently happens that physicians desire to indicate that a patient is poor and is a proper subject for charity. This is usually done by writing the letter P in the lower corner, or, if very poor, PP.

The pharmacist, although professional in spirit, must exercise business acumen in handling the prescription department. It is evident that there must be a reasonable profit, else the store could not long offer satisfactory service. The ingredients in a prescription are frequently negligible factors in determining the price. The real cost which must be considered in determining the price to be charged for a prescription is the time required for the services of the skilled pharmacist plus the cost of what is termed "overheads". This means the maintenance of the establishment. The time of the dispenser is probably the largest factor.

When it is realized that a competent prescriptionist who probably does not work more than 50 to 60 hours a week is being paid at least at the rate of about a dollar an hour and that even the simplest prescription, considering the time necessary to receive it, write the label, fill the prescription, check, wrap and deliver requires a minimum of from 15 to 20 minutes, there is at once an added cost of 25 to 35 cents. Add to this the proportion of overhead expenses, the cost of the ingredients and the container, and it is found that without any profit, the actual cost not infrequently exceeds the price usually charged. It is therefore desirable that the pharmacist and his assistants should follow a systematic plan of pricing so that there is a positive assurance that the cost is covered and a reasonable profit assured.

Investigations into the prices received for prescriptions in the average drug store have clearly shown the need for the adoption of scientific business methods in deciding upon the price to be charged. Where the old-fashioned method has been followed of having a flat price for a two-ounce mixture, a fixed amount for a dozen pills, etc., it has been shown that often a prescription is dispensed at an actual loss and the department frequently is conducted without any profit. This policy is often indirectly responsible for failure to establish a successful prescription pharmacy. The fundamental principles of business demand that to be successful the price charged must be sufficient to insure the use of the best ingredients and containers, the employment of skilled assistants, the payment of all other costs and expenses and the final making of a profit.

Many pharmacists have found that the adoption of such a policy has given them the opportunity to impress the physicians and the public by the quality of their service and to increase their business instead of reducing it.

But how shall this selling price be determined so that it is sufficient and yet not excessive? It involves, first, the exact cost of ingredients used in the prescription; secondly, the approximate cost of containers, labels, wrapping paper, etc.; thirdly, the labor and overhead cost, and, lastly, the desired profit.

The first of these factors is constantly changing and requires that the pharmacist frequently consult up-to-date price lists; he should not guess at prices but know the current market value, especially of drugs and chemicals. As ingredients are usually bought in comparatively large quantities, and as there

is a large percentage of waste and also loss from deterioration, it is customary to double the cost of materials in calculating the price of a prescription.

The cost of containers should also be known exactly and this with the cost of labels, paper, etc., should next be added to the price.

The actual time spent in compounding the prescription represents a definite cost and each prescription should carry its share of the general overhead expenses, such as rent, light, heat, insurance, etc., which make it possible to open the prescription department. Usually this is estimated, and the calculation for each prescription is based upon the time required, at a fixed rate per hour, say $1.50 or $2.00.

When the actual costs have been determined, the amount to be charged for profit may be given consideration. Sometimes this is included in the amount added for time consumed and that is the simplest plan; again it may be a definite addition to the actual cost, say of 10 to 20 per cent.

A plan for prescription pricing which has proved very satisfactory, is known as the *Evans' rule.* It is as follows: "Add a profit of 100 per cent to the actual cost of ingredients and container and then charge at the rate per hour decided upon in the particular store involved, for the actual time consumed in compounding."

The following general plan of pricing was originally suggested by the National Association of Retail Pharmacists, but has been somewhat modified to meet advances in costs (see Fig. 579).

FIG. 579

AVERAGE PRESCRIPTION PRICES

HOW TO CALCULATE PRICE. THIS IS IMPORTANT:

The price of the prescription is the compounding fee + the cost of the container + twice the cost of the material. (Exception: When the cost of the material is over $1.00, multiply the cost by 1½ instead of 2.)

COMPOUNDING FEES

I.—LIQUID PRESCRIPTIONS: Minimum total charge, 25c. All simple or compound mixtures, internal or external, dry or liquids and veterinary preparations are included in this table. Eye remedies, sprays for nose and throat, injections, etc., should be charged for as in the column: "Dose ℥ii—℥i".

Quantity	Dose 1–5 M.	Dose 10–25 M.	Dose ℥ss–℥i	Dose ℥ii–℥i	Gargle and Liniments only
½ oz.	.35	.30	.25	.20	.20
1 oz.	.45	.40	.30	.25	.20
2 oz.	.55	.45	.35	.30	.25
3 oz.	...	.50	.40	.35	.30
4 oz.	...	...	.45	.40	.35
6 oz.	...	...	.50	.45	.40
8 oz.	...	...	.55	.50	.45
12 oz.	...	...	.65	.55	.50
16 oz.	...	...	.70	.65	.60
32 oz.	...	...	.75	.80	.75

II.—DRY MIXTURES: Minimum total charge, 15c. These figures are compounding fees only. **Pills, Powders, Capsules, Wafers, Etc.**

Number	4	6	8	10	12	15	20	24	30	40	50
Fee	25c	30c	35c	40c	45c	50c	55c	60c	70c	85c	$1.00

Then every additional 25 up to one hundred, 25c. After that 20c. for every additional 25.

III.—OINTMENTS AND CERATES.

½ oz.	.30	2 oz.	.45	4 oz.	.65	8 oz	.85
1 oz.	.35	3 oz.	.55	6 oz.	.75	16 oz.	1.10

IV.—SUPPOSITORIES, BOUGIES, ETC.

1	.30	5	.55	12	.85	24	1.45
2	.40	6	.60	15	1.00	30	1.70
3	.45	8	.70	18	1.15	36	1.90
4	.50	10	.75	21	1.30		

CONTAINERS: Pill and Powder Boxes 10c; Screw Cap Vials 10c; Ointment Jars, ½ oz–1 oz., 10c; Collapsible tubes and box 10c; Bottles, 8 oz. or less, 5c; Glass-stoppered Bottles, three times the price of plain bottles.

In the above schedule it is suggested that not less than 10 cents be considered as the cost of ingredients in any prescription. If the actual cost of the ingredients is less than 10 cents, it is unfair to the pharmacist to consider a lower figure. Medicinal ingredients are often subject to serious deterioration and it is reasonable to consider this figure as a minimum.

The suggestion to double the market cost of ingredients in pricing a prescription is justified by the fact that the prescription sale is in principle a retail sale. The cost of materials may be considered as the wholesale cost. Weighing and measuring small lots from any purchase, always means waste and loss through deterioration, and therefore the justified doubling of cost.

If the ingredients are very expensive the schedule calls for one and one-half times the cost. A criticism frequently made concerning a schedule of this character is the fact that it will not apply to all conditions. The answer is that such is not intended.

Fig. 580

Sullivan transfer file

This pricing schedule is only a suggestion and a principle and pharmacists should modify the prices if necessary to meet the needs of the store. Sometimes they must be decreased, the price being too high, or perhaps they must be advanced if the neighborhood and the overhead expense demand a larger margin or gross profit.

Arguments for a schedule are:

1. Every one in the store gives the same prices for a prescription.
2. The proprietor is assured a reasonable profit.
3. A price is fixed which has been scientifically determined and in which there can be confidence should it be questioned.

Many other rules for pricing have been published but the one suggested has been found practicable and readily understood by everyone and it is flexible.

The Finished Prescription—When a prescription is sent from a retail pharmacy, it carries with it many indications of the skill or of the lack of skill of the pharmacist. It is difficult to advertise a pharmacy in the usual way, but the prescriptions sent out tell much of the training of the pharmacist and of his ideals. It is possible to speak of and demonstrate the dispensing equipment but one of the most potent factors in the advertisement of the dispensing pharmacy is the finished prescription as received by the patient.

The pharmacist seems to overlook the fact that within twenty-four hours after the time he fills a prescription it is almost certain to be examined by the physician. The pharmacist frequently says that he cannot easily meet the physician to promote his pharmaceutical service, but here is the opportunity. The prescription should carry, through its physical appearance, such evidence of the ability and care of the pharmacist that it will create confidence in his ability and insure large returns.

Every prescription leaving the store should, therefore, not only be correctly and skilfully compounded but the physical appearance of the prescription should indicate the pride and care which the pharmacist has taken in his professional work.

Filing, Binding, and Preserving the Prescription—There is very little uniformity of practice among pharmacists in the particulars of filing, binding and preserving prescriptions. The usual practice is one which is most inconvenient—*i.e.*, that of simply filing them away upon a long brass wire yearly, half yearly, or quarterly. By this plan they will certainly become in time torn, dirty, dusty, and fly-specked, and the file is very unsightly. The most satisfactory file of this type is known as the Sullivan transfer file (see Fig. 580). The stick file stands on the counter and is larger in diameter than the longer permanent file so that the prescriptions move freely. In transferring them the stick file is screwed to the long file, and all are slipped on without losing their order.

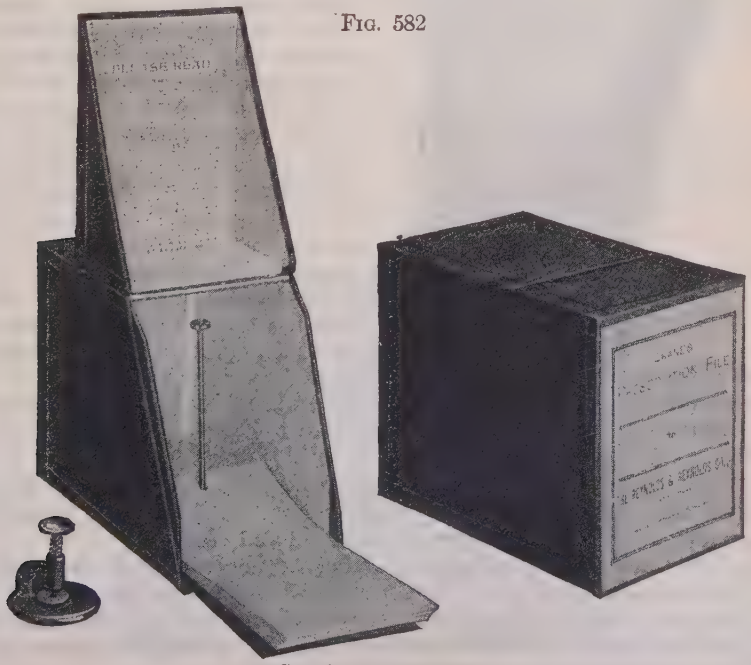
Fig. 581

Acme prescription book

The method of pasting prescriptions daily into a large prescription book is an improvement. The objection to this plan is, however, that the backs of the prescriptions cannot be examined readily, and in an active business the unwieldy books soon accumulate so as to be an inconvenience. Notwithstanding these seeming objections many stores doing a large prescription business use these books. Fig. 581 illustrates the Acme prescription book sold by the Whitall Tatum Company.

Many pharmacists copy their prescriptions into a book kept for the purpose. This plan is not always a judicious one. The chances of making errors are increased, and, in case of dispute, proof of the correctness of the copy would have to be produced.

Fig. 582

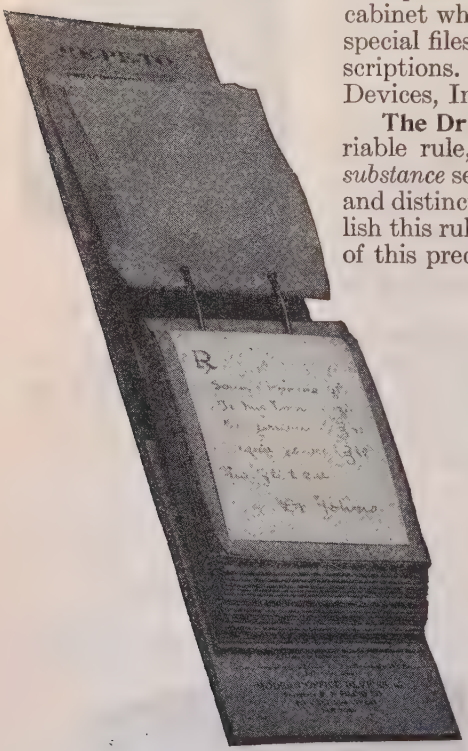


Crane's prescription file

Fig. 582 illustrates the Crane's prescription file, made by the Reynolds and Reynolds Company. The prescriptions are punched near the end and guide cards are provided for each 100 prescriptions, all being filed on a brass post, firmly attached to a wood base. Each file carries 1000 prescriptions and is slipped into a strong box. These boxes may be stacked so as to occupy a small space. One advantage of this file is the ease with which several prescriptions may be consulted simultaneously.

Figs. 583 and 584 illustrate the "Safeway" prescription file in which the prescriptions are pasted on a leaf of strong paper which is punched and held in book form in a strong binder. Each file carries 1000 prescriptions and they are stored in a wooden cabinet which is a part of the outfit. Note the special files for "narcotic" and for "liquor" prescriptions. This file is made by the Modern Office Devices, Inc., of New York City.

Fig. 583



"Safeway" prescription file

The Drug Store Label—It should be an invariable rule, in a drug store, that *every medicinal substance* sent out from the store *must have* a neat and distinct label upon it. It is necessary to establish this rule as a fixed custom or habit, for neglect of this precaution will often result in serious consequences. In addition, every package *should be labeled at once*, particularly in the case of prescriptions. The habit of permitting unlabeled packages to stand about, liable to substitution, will inevitably cause doubt, and give rise to some grave mistake, sooner or later. A very great diversity of opinion and taste is apt to prevail with regard to the most suitable style of label to select for general use. Formerly the home printer was exclusively depended upon, but the principle of division of labor has led to the establishment of "druggists' printing houses" in several sections of the country; this has resulted in cheapening labels, and although at one time it was quite common to see labels of an elaborately gaudy design (see Fig. 585) very few labels of that character are seen today.

The trend today is toward great simplicity in labels and even the border, almost universally used a few years ago (see Fig. 586), is now omitted (see Fig. 587).

Neatness, distinctness, and simplicity are cardinal principles in designing labels, and the reputation of many establishments is frequently judged from the character of the outward signs of neatness and care.

Fig. 588 illustrates the McCourt label cabinet which finds favor with many pharmacists because of the convenience in finding the desired label. The labels are printed on gummed paper and supplied in rolls. Each roll is placed in a division of the cabinet and a label may readily be pulled out and torn off by quickly drawing it across the knife edge.

Labeling Poisonous Substances—Whenever a poison is dispensed to customers upon an order, without being prescribed by a physician, the word poison should be distinctly written upon the label. If solid, and wrapped in paper, it should have two wrappers upon it, and both should be labeled poison. In the case of prescriptions, the word poison *should not appear upon the package or bottle unless the physician has so directed.* A careful pharmacist will be sorely tempted to prevent possible accident by pasting a poison label upon the package, but he is relieved entirely of responsibility if the dose is not excessive and if the physician has not directed it, because there is usually a special reason *for omitting it* from the label—namely, that of avoiding the possibility of frightening the patient and thus defeating the object of the prescription. When bottles contain prescriptions of dangerous potency, a degree of caution must, however, be aroused in the patient without causing undue alarm by attaching a sticker somewhat as follows: "Caution—take with care", or "Caution—drop with care". If a prescription contains inflammable ingredients such as collodion or ether a sticker should be added cautioning "Keep away from flame". If the medicine is poisonous and not to be taken internally a special label should be attached reading as follows: "Caution—not to be swallowed". When a poison label is to be used upon a bottle one should be pasted on both

obtained free from a metal ferrule, or a rubber-set shaving brush are most satisfactory and it pays to select one of good quality which should last for a long time.

FLOUR PASTE

Flour (wheat)	**4 oz. troy**
Water	**16 fl. oz.**
Nitric Acid	**1 fl. dr.**
Oil of Cloves	**5 min.**
Boric Acid	**10 gr.**

Thoroughly mix the flour, boric acid, and water, and strain the mixture through a sieve; add the nitric acid; apply heat, with constant stirring, until the mixture has thickened; when nearly cold, add the oil; strain it through coarse muslin if not perfectly smooth. This paste keeps well, and is much superior to tragacanth mucilage and ordinary paste. When required for pasting labels on tinned surfaces, the addition of 10 per cent of glycerin prevents labels from falling off after drying.

If an acid paste is not desired the following formula provides a very satisfactory label paste:

FLOUR PASTE

Flour (wheat)	**2 oz. av.**
Alum	**2 drachms**
Sodium Benzoate	**10 grains**
Oil of Cloves	**15 drops**
Water	**1 pint**

Rub the flour and alum to a smooth paste with the water, heat quickly to boiling with constant stirring, remove from the fire at the first indication of boiling, add the sodium benzoate and the oil, and mix thoroughly.

For some purposes a more adhesive paste is desirable, and a dextrin paste is recommended (see below).

DEXTRIN PASTE

White Dextrin	**1 lb.**
Syrupy Glucose	**2 oz. av.**
Aluminum Sulphate	**1 oz. av.**
Sodium Benzoate	**20 grains**
Water	**24 fl. oz.**

Mix the white dextrin, aluminum sulphate, and sodium benzoate with a portion of the water, rubbing to a smooth paste; add the glucose and the remainder of the water, and heat the mixture on a water bath, with occasional stirring, until it has become translucent; strain if necessary.

LABEL PASTE FOR TIN

Gelatin, granular	**4 oz. av.**
Sugar	**28 oz. av.**
Water	**88 fl. oz.**

Mix the ingredients and boil for ten minutes with constant stirring.

Some pharmacists prefer mucilage of tragacanth which is usually kept in an inverted wide-mouthed bottle, with the mouth covered with muslin or double cheesecloth, and resting in a small flat dish when not being used.

In pasting a prescription label to a box, bottle, or can, care should be used not to touch with the fingers the portion of the label which has been recently written upon, even if it has the appearance of being dry. A piece of blotting pad or filtering paper, slightly larger than the label, should be laid upon it, and pressed gently, smoothly, and evenly, so that the excess of paste which has exuded upon the edges may be absorbed. If a label has had too much paste applied, and the excess has not been pressed out as described, it will have a wrinkled appearance. Labels should be neatly trimmed, showing a very slight but uniform margin around the border. They should be pasted upon bottles *just above the center*, and never over the seams or mold marks, but half way between them.

Gummed labels, or labels printed on paper coated with a solution of dextrin, or gum, on one side, are largely used in some sections of the country. They are satisfactory in some localities where there is a dry atmosphere, but when used on the seaboard or in a damp atmosphere considerable loss is often experienced from their sticking together.

Label moisteners are available (see Fig. 589). The felt pad is continually moistened from the cylinder of water above. A moist piece of cotton is also very satisfactory for moistening gummed labels.

Arranging and Preserving Labels—A method of classifying labels must be adopted by each pharmacist which will be suited to his own requirements. The general rule is to arrange them in label drawers in the most convenient place in the store. The label drawers are preferably shallow, made of wood, and having compartments to receive the labels. Considerable space may be saved by having the compartments made of tinned iron instead of wood. The bottom of the drawer may be lined with cotton flannel, to prevent the labels from slipping underneath the tin divisions and becoming mixed by the continuous opening and closing of the drawer. It will be found convenient to separate the plain labels required constantly for articles in daily request from those of larger size or special design; and the former may be classified into labels for solids and labels for liquids. These may be arranged alphabetically in each drawer, so that they can be quickly found. *A regular system should be adopted and rigidly carried out; and when a place has been once fixed for a label, it should never be changed,* as few trifles give more annoyance than inability to find a label in a pressing rush of business.

FIG. 588

Use of McCourt label cabinet

FIG. 589

Label dampener

The upright label cabinets which have been contrived answer an excellent purpose where upright space can be spared.

The McCourt label cabinet, Fig. 588, is again referred to in this connection.

The Library—The pharmacist who is sincerely interested in his professional work will not only keep abreast of the scientific progress of the times by reading current literature, but will gradually accumulate a working library and a reference library which will enable him to perform his professional duties more satisfactorily and to act as scientific adviser to the public more intelligently. It is unfortunately true that many pharmacists overlook or neglect this feature, but the experience of those who properly equip themselves and the professional standing which they attain indicate that it is a factor of no mean importance in the development of professional pride and reputation.

It is thought advisable, therefore, to include for purposes of reference lists of books covering all phases of professional and merchandising activities for the convenience of those who may thus make use of it when emergency requires or opportunity arises.

No selective preference is given or advice offered in connection with specific purchases, of books, but authorities are mentioned in a number of fields, for there has long been a wise saying "Beware of the man of one book", which is supplemented and confirmed by another to the effect that "In the multitude of counsellors there is safety". No attempt is made to offer here a complete list of available books; it is believed, however, that if the books mentioned are purchased and used that the buyer will be prompted to find for himself many additional books for his growing and valuable library.

A "Five Foot" Shelf of Pharmaceutical Books [1]

(For a list of books on chemical analysis see page 1431)

List No. 1—(Approximately $35.00).

The United States Pharmacopœia, latest edition[3]

The National Formulary, latest edition[45]

The Dispensatory, latest edition (either the United States[3] or the National[4]

A treatise on pharmacy (latest edition) Remington[3], Caspari[4], or Arny[6]

A treatise on general chemistry. There is a confusing abundance of works to choose from, including Sadtler and Coblentz[3], Simon and Base[4], Deming[20], Newell[46], Attfield[4] and many others

Scoville's Art of Compounding[2]

New and Non-official Remedies[15], latest edition

A general formulary (like the Pharmaceutical Formulas[7], the Standard[8], Henley's[9], and the Scientific American Cyclopedia[10], The Era, The Druggists Circular)

List No. 2—(Approximately $65.00)
Total of 1 and the following:

A treatise on botany and pharmacognosy, such as Kraemer[20], Culbreth[4], Sayre[2], Youngken[2]

Lyons' Plant Names[14]

The Propaganda for Reform in Proprietary Medicines[15]

Nostrums and Quackery[15]

Useful Drugs[15]

A treatise on pharmaceutical arithmetic, such as Oldberg[16], Sturmer[17], Beal[18], Stevens[19] or Snow[44]

A treatise on pharmaceutical Latin, such as Sturmer[17], Muldoon[20], or Robinson[2]

Leach's Food Inspection and Analysis[20]

Beal's Prescription Practice[18]

Ruddiman's Incompatibilities in Prescriptions[20]

Robinson's Incompatibilities in Prescriptions[44]

Todd's Clinical Chemistry[44], a good all-round clinical laboratory book

List No. 3. (Approximately $100.00)
Total of 1 and 2 and the following:

A treatise on materia medica and therapeutics, such as Wood[3], Potter[2], Shoemaker[21], Bethea[21], Sollmann[5], Hare[4], or Bastedo[6]

Rideal's Disinfection

A book on industrial chemistry, such as Thorpe[22], Sadtler[3], Rogers[23], Molinari[2], or Allen and Aubert[23]

The Extra Pharmacopœia[24]

A treatise on organic chemistry, such as Loury and Harrow[20], or Norris[47]

A treatise on bacteriology for pharmacists, such as Schneider[2], Heinemann[25], Frost and McCampbell[22], McFarland, or Roddy

A treatise on veterinary medicine, such as Hiss[8] or the Chemist and Druggist's Veterinary Counter Practice[7]

One or two of the smaller books on the practice of pharmacy, such as Oldberg[28], Snow, Sayre and Havenhill[5], Stevens[4], Maltbie[29], Lucas[3], the latter an English book devoted largely to manufacturing processes

The United States Government publications[31] on the horse, the cow, poultry, swine, rodents, vermin, and many other subjects. The lists and prices may be obtained by application to Washington, D. C.

A book on Toxicology such as Trumper[2], or Underhill[5]

A medical dictionary such as Gould or Dorland[5]

The Condensed Chemical Dictionary[45]

Wood's Tablet Manufacture[3]

A treatise on soda water by Hiss[8], or any one of a half dozen other authors

Rudolphy's Directory of Drug Names[6]

Candy Medication, Fantus[44]

The Prescription, Wall[44]

Whys in Pharmacy, Ruddiman[20]

---

[1] These books may be obtained from the publishers, indicated in the second list by the number following the title, or they may be obtained through any dealer in medical, pharmaceutical or, other scientific books, such as the Philadelphia Book Co., 22 N. 9th Street, Philadelphia.

Books on Business—

These books are not included in the cost indicated for the previous lists.

Publishers—

The small figures refer to the publishers (or sellers) of the books whose names appear on page 1625.

45. The Chemical Catalog Company, 19 East 24th St., New York
46. D. C. Heath and Company, Boston, Mass.
47. McGraw-Hill Book Co., 239 W. 39th St., New York

In addition to modern pharmaceutical books there should always be available at least one of the professional journals, also a commercial journal, carrying a current price list and also the Journal of the American Medical Association. It would be desirable to have the magazine, "Hygeia", so placed that customers waiting for prescriptions, may read it, and the pharmacist should also be familiar with this magazine and its many suggestions for improving public health conditions.

The Laboratory—There should be associated with the pharmacy a special section or preferably a room devoted to the manufacture of pharmaceuticals and preparations and for the carrying out of clinical or bacteriological tests. It is desirable to have special equipment for this purpose, independent of the prescription counter as that department should be kept inviolate, ready for emergency calls. Many manufacturing operations require time for completion, and such should not be conducted in the section which is busy with daily store activities.

The possibilities for manufacture and analysis have been discussed elsewhere (see page 1427).

CHAPTER XCVII

INCOMPATIBILITY

INCOMPATIBILITY means disagreement. In Pharmacy it comprehends the study of the properties of substances which when prescribed in the same combination or when mixed together, show some physical change or undergo decomposition, or in some other manner show repellant or antagonistic qualities.

Types of Incompatibility—There are three subheadings under which incompatibility may be studied: *Therapeutic incompatibility*, *physical*, and *chemical incompatibility*.

Therapeutic incompatibility is exemplified in prescriptions containing ingredients which are antagonistic as regards their therapeutic effects. This type of incompatibility is entirely outside of the province of pharmacy so far as criticism or correction is concerned and will not be considered at all, except to point out that in some instances examples of this type of incompatibility are intentional and have the sanction of medical usage, as in the prescribing of morphine and atropine in combination.

Physical incompatibility is concerned with combinations of ingredients which are physically repellant to each other, such as oil and water, or with prescriptions or mixtures in which changes take place at the time of their compounding or subsequent thereto, in which no chemical alteration or decomposition of the ingredients is involved.

Chemical incompatibility is concerned with changes which take place in prescriptions or preparations in which, through chemical dissociation or decomposition, alterations in composition are produced, which may or may not be evidenced in a changed appearance of the preparation, or which may or may not have an effect upon its therapeutic value.

An intelligent study of incompatibility requires a comprehensive knowledge of the physical and chemical properties of a wide range of substances. Fundamental laws of both physics and chemistry are exemplified continually in a study of this subject. The possibilities are only limited by the number of substances used in prescription practice. No individual can ever expect to master the subject, nor can any treatise upon incompatibility completely cover it, except as regards underlying principles and more or less in complete lists of examples, for new remedies are coming into use constantly and unusual combinations will result as long as some few medical practitioners learn much of their prescription writing by the trial and error method. The medical curriculum provides for very little training in prescription writing, and much of what is taught is too early in the medical course to be remembered by the graduate when he enters practice. The medical journals and medical textbooks are for the most part silent upon the subject, so it becomes a distinctively pharmaceutical problem in which all of the scientific and professional knowledge of the pharmacist is required to be skilfully combined with much tact and diplomacy in order to handle the subject in a judicious and appropriate manner.

The proper management of the subject by the pharmacist who has a large prescription practice entails responsibilities, duties and opportunities which when properly combined and utilized lead to the development of mutual respect and coöperation between the physician and pharmacist in a field of work where the intelligent services of both are needed.

The pharmacist who advertises, as some have been known to do, "all physicians' prescriptions compounded exactly as written", advertises himself to his professional brethren, and to physicians, as either a fool or a knave, for the time comes to every pharmacist when he must exercise his professional skill in the interest of the physician and of the patient and must make minor changes in compounding a difficult combination in such a manner as to conform to the obvious intent of the prescriber.

In an historic legal case which occurred some years ago in Philadelphia, a physician wrote a prescription for a lotion composed of 1 fluidrachm of phenol in sufficient distilled water to make 1 fluidounce. The pharmacist dispensed the prescription exactly as written and the patient inserted the brush with which the lotion was directed to be applied, into the underlying layer of liquefied phenol, with the result that a severe burn was produced and a suit for damages was instituted against the physician for carelessness and malpractice. When in the course of the trial it was brought out in testimony that the addition of a fluidrachm of glycerin would have made a perfect solution of an obviously incompatible mixture, the pharmacist was censured for not having exercised his professional knowledge to overcome the evident lack of information of the part of the physician regarding the solubility of phenol in water.

Before entering into a discussion of specific examples illustrative of different types of incompatible prescriptions, some general principles may be considered.

There is a vast difference between being able to recognize an incompatibility and being able to overcome it. The making of an emulsion is an illustration of how a physical incompatibility may be properly overcome, for no one can deny the advantage of using gum in such a contingency.

Evidence of Incompatibility—There are a number of ways in which incompatibility may be evidenced. Among these are the following:

1. The failure to mix or dissolve when two or more ingredients are combined.
2. The separation of an immiscible liquid after the prescription is compounded.
3. The production of a precipitate, immediately or gradually, after the prescription is compounded.
4. The evolution of a gas gradually or with explosive violence.
5. The development of heat or of cold.
6. The exhibition of a change in color.
7. Liquefaction of solid ingredients.
8. Development of poisonous constituents by chemical reaction.

Incompatibility may also exist without any objective evidence of its existence. This is the most dangerous form and a few instances will be discussed at the close of this chapter.

There are many examples of incompatible preparations in which the incompatibility is intentional. In some of these cases corrective measures are applied in order to provide a presentable and satisfactory preparation. Emulsions are illustrative of this type. In other cases, as in mixtures containing insoluble solids where the insoluble material is of importance, the efforts of the pharmacist are directed toward compounding the preparation so as to insure the fine subdivision of the insoluble solid and its accompanying ease of suspension when the preparation is used or administered. The classic example of the prescription in which zinc sulphate and lead acetate react

to form soluble zinc acetate and insoluble lead sulphate illustrates this type and will be considered in detail in its proper place. (See incompatible prescription, number 16.) Still another type, and probably the most common of all is the prescription in which unexpected precipitation occurs. The cause of precipitation may be obvious or it may be obscure, but as a fundamental principle of magistral pharmacy, the difficulty should be remedied if it is possible to do so.

Some careless pharmacists simply follow the line of least resistance and put a "shake" label upon every prescription in which a precipitate appears, regardless of whether the exercise of a little skill in compounding would eliminate the trouble. In the following list of ways to be considered in remedying such a condition, reference is given to the number of the prescription in this chapter illustrative of the particular method mentioned.

1. Omission of an unimportant ingredient of no therapeutic significance (see incompatible prescription, number 25).
2. Addition of an inert constituent, the mere presence of which corrects the difficulty (see incompatible prescriptions, numbers 2, 3, 12 and 18).
3. Changing the character of the solvent (see incompatible prescriptions, numbers 10 and 19).
4. Emulsification (see incompatible prescription, number 1).
5. Adding the ingredients in a certain order (see incompatible prescriptions, numbers 8, 29 and 39).
6. Increasing the bulk of the prescription by adding an additional amount of the vehicle (see incompatible prescription, numbers 11 and 15).

It must be emphatically stated that when any important change is made in compounding a prescription, such as the omission of an ingredient or a change in the character of the solvent, the physician should be consulted beforehand if possible, or failing in that should be notified of the change, and the reasons therefor.

This by no means exhausts the possibilities of what may or must be done to overcome an obvious incompatibility. Other methods of procedure are discussed in the specific examples which follow.

The detailed consideration of the subject may best be accomplished by making no distinction in the classification as to whether the cause is physical or chemical—but following the list on page 1628 outlining the ways in which incompatibility may be evidenced.

Typical Incompatible Prescriptions

1. **The failure to mix or dissolve when two or more ingredients are combined**—This condition is always due to physicial causes. There are many examples, of which the following are illustrations.

No. 1

℞ Olei Olivæ f℥ii
Aquæ Destillatæ f℥ii
M. Make an emulsion *secundum artem.*
Sig.—Take a teaspoonful three times a day.
Dr. J.

Here the appropriate procedure is obvious. The proper amount of gum should be used (see Chapter on Emulsification), and an emulsion prepared by the Continental method.

No. 2 ℞ Bromoformi 2 cc.
Syrupi 20 cc.
Aquæ Fœniculi 40 cc.
M. ft. mist.
Sig.—2 cc. in water every 4 hours.
Dr. G.

Here is another example of physical incompatibility in which the liquids are mutually immiscible. In this case simple emulsification with gum will not avail unless the amount of gum is so great that the mixture will scarcely pour from the bottle. Bromoform has such slight viscosity and is so much heavier than water that it will not emulsify satisfactorily by itself. If, however, 5 cc. of olive oil or almond oil is mixed with the bromoform, this mixture may then be emulsified by the aid of gum and a portion of the fennel water and the subsequent dilution will enable a homogeneous preparation to be dispensed.

No. 3 ℞ Phenolis ℥i
Aquæ Destillatæ q.s. ad f℥i
M. ft. sol.
Sig.—Apply as directed with a camel's hair brush.
Dr. J.

Here is an example of a physical incompatibility due to forgetfulness on the part of the physician that phenol is not soluble in water to the extent directed. In this case, the obvious remedy is for the pharmacist to add a volume of glycerin equal to that of the phenol, *i.e.*, one fluidrachm. This will make a clear and permanent solution. This prescription has already been discussed under the general introductory principles. In such a case as this, it is imperative that the pharmacist utilize his professional skill in compounding the prescription in such a manner as to protect the patient from possible injury, as might result if the prescription were dispensed as written.

No. 4 ℞ Potassii Chloratis ℥iv
Phenolis gtt. xv.
Infusi Salviæ q. s. f℥iv
M. ft. sol.
Sig.—Use as a gargle.
Dr. M.

This is another example of an excess of the substance to be dissolved. The potassium chlorate is in great excess over the amount needed to make a saturated solution. If heat is used, the potassium chlorate will go into solution temporarily, but will crystallize out as the solution becomes cold. In either case the excess of potassium chlorate, if allowed to remain, will act as an irritant to the throat when used as a gargle. This preparation should be filtered before being dispensed.

No. 5 ℞ Magnesiæ Ponderosæ ℥iss
Massæ Hydrargyri ℥ss
Sucrosi ℥i
Aquæ Menthæ Piperitæ q. s. ad. f℥iv
M. ft. mist.
Sig.—One teaspoonful at bedtime.
Dr. C.

This is an example of a common type of physical incompatibility in which active insoluble constituents are present in a prescription. Filtration or solution are both out of the question in such a case. The only thing to be done is to dispense the mixture exactly as written and put on a "shake well" label.

No. 6 ℞ Petrolati Liquidi f℥ii
Fluidextracti Cascaræ Sagradæ f℥i
M. ft. mist.
Sig.—Take a dessertspoonful at night.
Dr. C.

In this case, the cause of the incompatibility is apparent. Mineral oil will not dissolve hydroalcoholic liquids. There is no emulsifying agent that can be used in such a case, and there is no remedy for the condition. The prescription must be dispensed as written, and must have a "shake" label. This same combination is sometimes encountered with the additional ingredient of precipitated sulphur which adds to the difficulties involved, for it is soluble in neither of the liquids and the combination can only be dispensed as an unattractive looking mess.

No. 7 ℞ Acidi Borici ℥i
Aquæ Destillatæ f℥ii
M. ft. sol.
Sig.—Apply locally to eyes with eye cup.
Dr. C.

This is another case of incomplete solution. The physician undoubtedly desires a saturated solution of boric acid but instead of writing for it as such, writes a prescription for a specific amount of boric acid to be dissolved in a directed amount of water. In this case, the amount of water is insufficient. It would require just about 2½ fluidounces of water to dissolve one drachm of boric acid. The proper procedure in this case would be to dispense a saturated solution of boric acid, as that is undoubtedly intended. To dispense this prescription exactly as written, allowing the excess of boric acid to remain in the bottle, might result in injury to the patient, as eye lotions should always be dispensed clear.

No. 8 ℞ Zinci Oxidi ℥ii
Linimenti Calcis f℥ii
M. ft. mist.
Sig.—Apply locally.
Dr. D.

If the zinc oxide is added to the previously prepared lime liniment, the emulsification of the latter is destroyed and a curdy mixture results. If, however, the zinc oxide is first triturated with the lime water (1 fluidounce) and the creamy liquid transferred to a bottle and agitated thoroughly with the linseed oil (1 fluidounce) a smooth, satisfactory preparation results. This is an excellent example of the influence of changing the order of mixing the ingredients.

2. **The separation of an immiscible liquid after the prescription is compounded**—There are a number of possibilities of this kind, a few of which seem to occur frequently in prescription practice.

No. 9 ℞ Potassii Bromidi ℥v
Aquæ Menthæ Piperitæ f℥i
M. ft. sol.
Sig.—One half teaspoonful at bedtime.
Dr. X.

This is an example of a physical incompatibility in which the selective preference of a solvent for a second solute after it has been previously saturated with another. Peppermint water is a saturated aqueous solution of peppermint oil. When this solution is used as a solvent for potassium bromide, the latter is taken up almost to saturation, with the result that about half of

the oil of peppermint previously dissolved is thrown out of solution and separates in the form of floating oily globules. This phenomenon is sometimes referred to as "salting out". To dispense the preparation in this turbid condition would not be productive of any harmful result, but would not be "good pharmacy".

There are two alternatives possible. The prescription may be compounded as written and the solution subsequently filtered to remove the oil globules; or the peppermint water may first be reduced in strength by adding an equal amount of distilled water, in which case it would require but ½ fluidounce of peppermint water to compound the prescription which would then require no filtration and the result would be practically the same as in the previous case, with much less trouble.

No. 10

℞ Potassii Bromidi ℥v
Chloralis Hydratis
Elixir Aromatici f℥iv
M. ft. sol.
Sig.—One teaspoonful at bedtime.

Dr. Y.

This is another case of physical incompatibility and selective preference of solvents for certain constituents. The potassium bromide exercises a selective preference for the water present in the simple elixir and the chloral hydrate does the same with the alcohol. When first compounded, the prescription appears to be in the form of a perfect solution. Turbidity almost immediately ensues, and the preparation ultimately separates into two layers. The lower layer, which is the greater in bulk, contains all of the potassium bromide and the water, with a portion of the alcohol, while the upper layer contains all of the chloral and the remainder of the alcohol. This condition is potentially dangerous, as the colorless supernatant layer might easily be overlooked by the patient, even if a "shake well" label were attached, and an overdose of chloral might be taken. Several alternatives have been suggested as remedies. The simple elixir may be diluted with an equal volume of water, the prescription may be doubled in bulk by dilution with water and the dose correspondingly increased; the aromatic elixir may be replaced by an aromatic water or by one of the elixirs of the National Formulary of low alcoholic strength. Whichever procedure is adopted, the physician should be notified and proper notation should be made upon the original prescription to ensure uniformity in case of a "refill".

No. 11

℞ Spiritus Æthylis Nitritis f℥iv
Potassii Citratis ℥i
Syrupi Acidi Citrici
Aquæ Destillatæ aa f℥i
M. ft. sol.
Sig.—One teaspoonful every two hours.

Dr. Z.

This is another example of physical incompatibility depending upon the selective preferences of solvents. In this case, the ethyl nitrite separates out in concentrated alcoholic solution upon the surface of the nearly saturated solution of potassium citrate. This is undoubtedly a potentially dangerous condition and can only be remedied by increasing the bulk of the prescription by adding more water, and making a corresponding increase in the dose.

3. **The production of a precipitate, immediately or gradually after the prescription is compounded**—This condition may be due to physical causes or to chemical changes. It is probably the most frequently encountered type

of incompatibility. Examples will be given of a number of prescriptions illustrating various causes of this condition.

No. 12 ℞ Tincturæ Cannabis Indicæ
Tincturæ Aurantii Amari aa f℥i
Tincturæ Rhei f℥ii
Misc.
Sig.—One half teaspoonful at night.
Dr. R.

This is an instance of physical precipitation caused by mixing the highly alcoholic, resinous tincture of cannabis with tinctures of lower alcoholic strength, the resinous matter of the cannabis being precipitated. The best procedure to follow in this case is to use a small amount of acacia which will aid in overcoming the difficulty and will prevent the resins from depositing permanently upon the inside surface of the bottle.

When alcoholic solutions of resins such as preparations of cannabis, guaiac, etc., are to be diluted with aqueous liquids, the addition of an equal volume of honey to the alcoholic liquid and the adding of this mixture slowly to the aqueous liquid, aids in effecting a satisfactory suspension of the resins.

No. 13 ℞ Tincturæ Nucis Vomicæ f℥ss
Infusi Gentianæ Compositæ f℥iiss
Tinctura Cinchonæ Compositæ f℥iii
Misc.
Sig.—One teaspoonful three times a day before meals.
Dr. C.

In this case, the precipitate consists of drug extractives thrown out on account of the differing alcoholic strengths of the ingredients. The amount of precipitate is not very great, but inasmuch as it might contain some of the active principles, carried down by adsorption, it is not proper to filter the mixture, but it may be dispensed with a "shake" label.

No. 14 ℞ Magnesiæ Sulphatis ℥i
Tincturæ Zingiberis f℥i
Tincturæ Aurantii Dulcis f℥i
Aquæ Menthæ Piperitæ f℥ii
M. ft. sol.
Sig.—One teaspoonful before breakfast.
Dr. E.

The magnesium sulphate may be dissolved in the peppermint water but as soon as the alcoholic tinctures are added crystallization of the magnesium sulphate takes place, and in a very short time almost the entire amount of the salt will have separated in a crystalline mass in the bottom of the bottle, and no amount of agitation will effect its incorporation. In such a case the physician should be consulted before making any change.

No. 15 ℞ Sodii Bromidi ℥iv
Elixir Pepsini et Rennini f℥ii
M. ft. sol.
Sig.—One teaspoonful every two hours.
Dr. B.

In this prescription, a slimy precipitate occurs which is difficult to incorporate by shaking. The precipitate consists of the enzymes of the elixir, which are salted out by the sodium bromide. The best remedy would be to reduce the concentration, with the consent of the physician, by diluting the mixture to four fluidounces and doubling the dose.

No. 16

℞ Plumbi Acetatis ℥ss
Zinci Sulphatis gr.xv
Aquæ Rosæ f℥iv
M. ft. injectio.
Sig.—Use as an injection.
Dr. B.

This is a classic example of an intentional incompatibility in which precipitation occurs, the precipitate being produced by chemical reaction. Lead acetate and zinc sulphate are used in clear solutions, separately, for their astringent effects when applied externally. When solutions of the two salts are mixed, mutual decomposition occurs, soluble zinc acetate remaining in solution and insoluble lead sulphate separating as a precipitate. It has been found in practice that when this prescription is compounded so as to produce a finely divided precipitate of lead sulphate which can be incorporated uniformly at the time of injection, the coating of lead sulphate deposited on the mucous surfaces, exercises a soothing and protective effect which is advantageous.

Great care must be exercised in compounding this prescription to avoid the formation of a coarse granular precipitate which would be irritating. If the lead acetate and zinc sulphate are triturated together in a dry condition and the rose water gradually added, such a coarse granular precipitate as it is desirable to avoid would be formed. The proper method of compounding this prescription is to dissolve the zinc sulphate and the lead acetate separately, each in two fluidounces of rose water, and mix these solutions by pouring the lead acetate solution gradually into the zinc sulphate solution with constant agitation. This same principle, which follows the fundamental rules governing precipitation (see Chapter XIX, page 216), may be applied in many similar instances when precipitates are produced in compounding prescriptions.

No. 17

℞ Quininæ Sulphatis gr.x
Potassii Acetatis gr.xv
Acidi Sulphurici Diluti gtt.xv
Aquæ Cinnamomi f℥i
M. ft. sol.
Sig.—A tablespoonful at a dose.
Dr. W.

Prescriptions containing quinine salts in liquid mixtures are not so commonly encountered as they were some years ago, but they are occasionally seen even yet. This one illustrates a type in which precipitation of an almost insoluble salt of quinine results. In this case, it is the formation of quinine acetate which is the cause of the trouble. The prescription becomes almost solid from the voluminous character of the precipitate, and should not be dispensed at all, as the liquid is so thick that it cannot be poured from the bottle. This is an instance where the physician should be called upon to revise his prescription. The use of aromatic elixir as a vehicle instead of cinnamon water remedies the difficulty, but it would not be advisable to make such a change without consulting the physician.

No. 18

℞ Magnesii Sulphatis
Potassii et Sodii Tartratis aa ℥i
Sodii Phosphatis ℥ss
Tincturæ Capsici mxx
Aquæ ad f℥ii
M. ft. sol.
Sig.—One teaspoonful every hour.
Dr. X.

The sodium phosphate is the disturbing factor in this combination. It produces gradually a flocculent precipitate of magnesium phosphate. The

addition of a small amount of tartaric acid to the solution of the first two ingredients in one-half of the water will prevent the formation of this precipitate when the solution of the sodium phosphate, in the remainder of the water, is added.

No. 19

℞ Argenti Nitratis gr.xxv
Liquor Sodii Chloridi Physiologici f℥vi
M. ft. sol.
Sig.—Use as an injection, as directed.
Dr. L.

Soluble silver salts are incompatible with chlorides. In this case, the silver would be entirely thrown out of solution as the insoluble silver chloride. Physiological salt solution is an advantageous solvent for some types of injections, but not for this one. Distilled water should be used as the solvent and the physician should be notified of the change. Even rose water, which is sometimes prescribed as a solvent for silver nitrate, will decompose some of the silver salt with the formation of a dark precipitate.

No. 20

℞ Strychninæ Sulphatis gr.i
Potassii Bromidi ℥viii
Aquæ Destillatæ q. s. ft. f℥viii
M. ft. sol.
Sig.—One teaspoonful every four hours.
Dr. J.

One who is inexperienced in prescription practice would quickly compound this and send it out without a "shake" label. This procedure would be dangerous. A transparent solution results at first, but within a few hours, the sparingly soluble strychnine begins to separate as a microcrystalline precipitate, which by its small amount and inconspicuous character might be entirely overlooked by the patient and be allowed to deposit in the bottom of the bottle. This is due to the slightly alkaline reaction of the potassium bromide. Little or no strychnine would be present in the clear liquid which would be poured off as the various doses are administered, but in pouring out the last dose there is great danger that the entire grain of strychnine might be taken at one dose and dangerous results follow. The proper procedure in prescriptions of this type is to put on a "shake" label, whether the prescription is perfectly clear at the time of dispensing or not, as it has been found by experience that this precipitate sometimes does not make its appearance for some hours after the solution has been made.

No. 21

℞ Morphinæ Sulphatis gr.ii
Spiritus Ammoniæ Aromatici f℥ii
Aquæ Menthæ Piperitæ f℥vi
M. ft. sol.
Sig.—One teaspoonful when required.
Dr. R.

Here is another and more common type of alkaloidal precipitation in which an alkaloidal salt, which is soluble in water, is decomposed by an alkali with the liberation of the insoluble free alkaloid. There are many possibilities of this kind and the prescription in each case requires a "shake" label. If the pharmacist is well acquainted with the physician writing such a prescription a little missionary work may not be amiss, for, as a general principle, it is dangerous to have a powerful active ingredient in a state of suspension in a mixture.

No. 22 ℞ Cocainæ Hydrochloridi gr.v
Sodii Boratis gr.x
Aquæ Destillatæ f℥i
M. ft. sol.
Sig.—Two drops in each eye at night.
Dr. B.

The alkalinity of the borax causes the precipitation of the cocaine and the production of an irritating turbid mixture. The proper remedy is to replace the sodium borate with an equal amount of boric acid which will make a clear solution in accord with the expectation and desire of the physician prescribing it.

No. 23 ℞ Sodii Salicylatis ℥ii
Syrupi Acidi Citrici f℥iv
M. ft. sol.
Sig.—One teaspoonful every two hours until pain is relieved.
Dr. F.

This prescription illustrates a frequently occurring type in which salicylates or benzoates are present as ingredients. Sodium salicylate is completely soluble in plain syrup in the amount prescribed, but the citric acid decomposes the sodium salicylate with the formation of sodium citrate and free salicylic acid. Free salicylic acid is only soluble in aqueous solutions to the extent of about one grain to the fluidounce, so that a voluminous precipitate of salicylic acid occurs, which not only makes the prescription unsightly and difficult to dispense, but makes it more likely to be irritating to the alimentary tract. Here is another opportunity for missionary work with the physician who cannot possibly be expected to keep in mind all of the variations in solubility of the hundreds of substances that he is called upon to prescribe.

No. 24 ℞ Acidi Acetylsalicylici ℥i
Potassii Iodidi ℥i
Glycerini f℥iv
Aquæ Anisi q. s. ad f℥iv
M. ft. sol.
Sig.—One teaspoonful every three hours.
Dr. N.

A gradual separation of a crystalline precipitate occurs in this prescription. Upon investigation it has been found to consist of free salicylic acid. Acetylsalicylic acid is easily dissociated in aqueous solutions with the liberation of salicylic and acetic acids. Even the use of solution of potassium or sodium citrate as the solvent, in the hope of preventing this change, is not effective. For this reason acetylsalicylic acid is usually prescribed in tablets or capsules.

No. 25 ℞ Quininæ Sulphatis gr. xxx
Acidi Sulphurici Diluti q. s.
Fluidextracti Glycyrrhizæ f℥ii
Syrupi f℥iv
M. ft. sol.
Sig.—One teaspoonful three times a day.
Dr. R.

It is not likely that this combination is frequently prescribed at the present time. As it illustrates a principle of procedure, however, it is worthy of consideration. The question hinges on the interpretation of the quantity "q. s." following the second ingredient. It was formerly the practice to dispense quinine sulphate in acidulated preparations to insure perfect solution. It was later discovered that the more thorough the solution the more

intensely bitter was the taste. Then came the practice of using glycyrrhiza preparations for masking the bitterness of the quinine. In the above prescription, if any sulphuric acid is used at all, it will not only intensify the bitterness of the quinine, but it will have the effect of diminishing the sweetness of the glycyrrhiza, by precipitating out the glycyrrhizin, which is only soluble in slightly alkaline mixtures.

The sensible interpretation of "q. s." in this prescription, therefore, is *none at all.* This agrees with the obvious intent of the prescriber who put the fluidextract of glycyrrhiza in to get the benefit of its sweetness.

No. 26 ℞ Liquoris Plumbi Subacetatis f℥ii
Mucilaginis Acaciæ f℥ii
Aquæ q. s. ad f℥xvi
M. ft. sol.
Sig.—Apply on a cloth kept constantly moistened.
Dr. Y.

Solution of lead subacetate gives a thick gelatinous precipitate with mucilage of acacia. The lumpiness of this precipitate may be minimized by diluting the lead subacetate solution with 6 fluidounces of water and the mucilage of acacia with an equal amount, and pouring the former into the latter with constant and vigorous agitation. Even at its best, however, the mixture is thick and unsatisfactory for use in the manner directed. If the physician is available, the suggestion should be made to replace the 2 fluidounces of lead subacetate solution with 2 fluidounces of a 25 per cent solution of normal lead acetate which will have a similar therapeutic effect and will not precipitate the acacia.

No. 27 ℞ Strontii Bromidi ℥ii
Liquor Potassii Citratis q. s. f℥ii
M. ft. sol.
Sig.—One teaspoonful at night.
Dr. M.

The precipitate which occurs in this prescription is strontium citrate, which is sparingly soluble and comes down rather gradually. The preparation may be dispensed with a "shake" label.

Another somewhat similar instance is when aromatic spirit of ammonia is present in a prescription with strontium bromide, the precipitate in this case being strontium carbonate.

These incompatibilities of the strontium salts are easily understood by the pharmacist, but are usually a surprise to the physician who has prescribed other bromides such as potassium, sodium, lithium, etc., in similar combinations with no occurrence of precipitation.

No. 28 Liquoris Potassii Arsenitis
Syrupi Ferri Iodidi aa f℥i
Misce
Sig.—Two drops three times a day, increasing the dose a drop each day until five drops are taken.
Dr. D.

A precipitation of ferrous carbonate occurs in this prescription in consequence of the alkalinity of the Fowler's solution. The preparation may be dispensed with a "shake" label.

No. 29

℞ Hydrargyri Chloridi Corrosivi gr.iii
Mucilaginis Acaciæ f℥i
Liquoris Calcis
Aquæ Destillatæ aa q. s. f℥iv
M. ft. sol.
Sig.—Apply locally.
Dr. R.

This is an interesting example of a prescription which when compounded in one order of mixing will show precipitation, while if another order is followed the preparation will be in the form of a clear solution.

If the lime water is added directly to the corrosive sublimate, a reddish-yellow precipitate of mercuric oxide will occur which will not redissolve when the other ingredients are added. If, however, the corrosive sublimate is first dissolved in the distilled water, the mucilage of acacia added next, and the lime water added last, no precipitation occurs.

4. **The evolution of a gas, gradually or with explosive violence**—Chemical reaction frequently results in the evolution of gaseous constituents. This is sometimes intentional and desirable, as in the administration of granular effervescent salts, or of an effervescing solution prepared extemporaneously. Sometimes, however, the effervescence is unexpected and sometimes the gas is liberated with explosive violence, occasionally with serious results. The condition may occur in either solid or liquid mixtures.

No. 30

℞ Ammonii Chloridi ℥ss
Ammonii Carbonatis gr.xl
Syrupi Scillæ f℥i
Syrupi Tolu ad f℥ii
M. ft. sol.
Sig.—One teaspoonful as required.
Dr. R.

In this prescription, carbon dioxide is liberated from the ammonium carbonate by the acetic acid present in the syrup of squill. Explosions have resulted from combinations of this kind having been carelessly compounded by placing the ingredients successively in the bottle and stoppering securely. The best method to pursue in compounding this prescription is to use a capacious mortar, and permit the effervescence to cease entirely before transferring the mixture to the bottle.

No. 31

℞ Phenolis gr.xxv
Sodii Bicarbonatis
Sodii Boratis aa ℥i
Glycerini f℥i
Aquæ ad f℥iv
M. ft. sol.
Sig.—Apply locally.
Dr. D.

The reaction involved in this prescription is similar to that observed in preparing Dobell's solution. There is no acid present to react with the sodium bicarbonate and yet effervescence occurs. The explanation is found in the fact that glycerin decomposes alkaline sodium borate with the production of neutral sodium metaborate and free boric acid, and this latter constituent then reacts with the sodium bicarbonate to produce the effervescence.

No. 32 ℞ Ammonii Chloridi ℥ii
Potassii Bicarbonatis ℥iss
Misturæ Glycyrrhizæ Compositæ f℥iii
M. ft. sol.
Sig.—One teaspoonful at night for cough.
Dr. S.

In this prescription, no effervescence will be observed, but decomposition changes will gradually take place with the liberation of free ammonia from the ammonium chloride. This is caused by the alkalinity of the potassium bicarbonate, which gradually changes into the carbonate. It is not a satisfactory prescription to dispense for this reason and the physician should be induced to leave out the potassium bicarbonate altogether.

No. 33 ℞ Fluidextracti Buchu f℥ii
Fluidextracti Uvæ Ursi f℥iiiss
Spiritus Æthylis Nitritis f℥ss
M. ft. sol.
Sig.—One teaspoonful three times a day.
Dr. F.

In this combination the ethyl nitrite is decomposed by the astringent principles present in the fluidextract of uva ursi. It takes many hours to complete the reaction. It is customary to warn the patient to release the stopper from time to time to relieve the presence of gas which may develop, and the stopper should not be tied down at the time of the delivery of this prescription. If the patient calls for it, warning should be given of the possibilities of the stopper being expelled or the bottle bursting if the stopper is not released within a comparatively short time. Damage suits have resulted from injury to expensive clothing when such warning was not given and the bottle burst before the patient had reached home.

No. 34 ℞ Quininæ Sulphatis gr.xl
Sodii Thiosulphatis ℥i
Acidi Sulphurici Aromatici f℥i
Aquæ Destillatæ q. s. ft. f℥iv
M. ft. sol.
Sig.—One teaspoonful three times a day.
Dr. Q.

This combination illustrates another type in which a gas is gradually evolved. The obvious thing to expect here is an odor of sulphur dioxide, as that gas is given off when either sulphites or thiosulphates are acidulated. The quinine sulphate in this case must have a modifying effect upon the reaction for the gas that is evolved in this case is the offensively smelling hydrogen sulphide, which makes the prescription disagreeable and impossible to take.

No. 35 ℞ Tincturæ Nucis Vomicæ f℥i
Acidi Nitrohydrochlorici f℥ss
M. ft. sol.
Sig.—Five drops, well diluted with water, to be taken before meals.
Dr. C.

Strongly alcoholic liquids are acted upon by strong acids with the formation of corresponding ethyl esters. These esters volatilize readily and in a tightly-stoppered bottle may generate enough pressure to cause an explosion. Several instances are on record when serious results have followed the dispensing of such a combination as this in a bottle that was tightly stoppered,

No. 36

℞ Potassii Permanganatis ℥ss
Glycerini f℥ii
M. ft. sol.
Sig.—Apply as directed.

Dr. D.

This is a dangerous combination which cannot be compounded without decomposition, and numerous instances are on record where violent explosion has resulted with serious results to the compounder.

No. 37

℞ Sodii Bicarbonatis gr. x
Hydrargyri Chloridi Mitis gr. xv
Extracti Cascaræ Sagradæ gr. xv
Misc. ft. pil. No. X
Sig.—One pill at night.

Dr. E.

A gas may be evolved from a prescription containing solid or semi-solid ingredients. In the above prescription the acid resins of the drug extracts act upon the sodium bicarbonate with the gradual liberation of carbon dioxide. which causes the pills to swell, sometimes to such an extent as to force the cover off the box.

No. 38

℞ Potassii Chloratis ℥i
Acidi Tannici ℥i
M. ft. chart.
Sig.—Dissolve in one pint of water and use as a gargle.

Dr. O.

Potassium chlorate should never be triturated with organic compounds nor with oxidizing agents, for fear of explosion. It is possible to pulverize these ingredients separately and mix them gently without danger.

5. **The development of heat or of cold**—A change in temperature frequently takes place in compounding a prescription. This may or may not be accompanied by chemical change and may be entirely without significance. When potassium iodide is dissolved in water to make a saturated solution, as is frequently directed, the phenomenon of cold is observed as the salt dissolves. On the other hand, when the analogous compound, sodium iodide, is dissolved in the same manner, the phenomenon of heat is observed. These are merely physical changes and are of no importance as affecting the integrity of the finished solution. The following prescription is an example of the production of heat where the order of mixing is of importance to avoid excessive reaction.

No. 39

℞ Iodi 5 Gm.
Alcoholis 50 cc.
Olei Terebinthini q. s. 100 cc.
M. ft. sol.
Sig.—Apply as directed.

Dr. V.

If the iodine is added to the oil of turpentine, a violent reaction ensues and the mixture may even catch fire. If the iodine is first dissolved in the alcohol and this solution gradually added to the oil of turpentine, the reaction will be very much moderated, although some heat may be developed.

6. **The exhibition of a change in color at the time of compounding or later**—This may show itself by decolorization of a previously colored mixture, by the development of color in solutions previously free from color, or by alteration of the color of a preparation.

No. 40

℞ Tinctura Ferri Chloridi f℥i
Acidi Phosphorici Diluti f℥i
M. ft. sol.
Sig.—Ten drops well diluted, to be taken before meals.
Dr. G.

In compounding this prescription, the golden yellow color of the tincture of ferric chloride will be entirely discharged and a colorless solution will result. This is due to the formation of ferric phosphate which is held in solution by the liberated hydrochloric acid.

No. 41

℞ Tinctura Iodi f℥i
Aquæ Ammoniæ f℥i
Aquæ f℥i
M. ft. sol.
Sig.—Apply as directed.
Dr. X.

In this case, not only is decolorization of the iodine brought about but the dangerously explosive compound, nitrogen iodide, is produced. Combinations of iodine and ammonia should always be cautiously handled for fear of producing this compound, which is one of the most unstable and violent explosives known to science.

No. 42

℞ Magnesii Carbonatis ℥i
Magnesii Sulphatis ℥i
Glycerini f℥ss
Infusi Rosæ Acidi aa f℥viii
M. ft. mist.
Sig.—One teaspoonful every three hours.
Dr. M.

The beautiful red color of the acid infusion of rose is changed to a brilliant green by the alkaline effect of the magnesium carbonate. Effervescence is also produced in compounding this preparation.

No. 43

℞ Antipyrini ℥ii
Spiritus Æthylis Nitritis f℥iv
Syrupi q. s. ad f℥iv
M. ft. sol.
Sig.—One teaspoonful every two hours until fever abates.
Dr. I.

This prescription has been the subject of much comment, and some years ago of much controversy. A color change is produced, usually a brilliant blue or green, but even a red color has been reported. The formation of the green color was at first believed to be associated with the production of a toxic substance. Investigation showed the new substance to be a "nitro" derivative of antipyrin without harmful effects, and it is customary to dispense the prescription as written, warning the patient, however, that a change in the color of the liquid may occur.

No. 44

℞ Potassii Chloratis ℥i
Tinctura Ferri Chloridi f℥i
Acidi Hydrochlorici f℥i
Antipyrini gr. xxx
Aquæ Destillatæ q. s. f℥viii
M. ft. sol.
Sig.—One teaspoonful every three hours.
Dr. S.

In this case the therapeutic effect of the antipyrin is negligible. The reason for its inclusion in some sections of the country where this combination is popular is the production of a beautiful red color which makes the preparation much more attractive looking.

No. 45

℞ Tincturæ Guaiaci f℥i
Mucilaginis Acaciæ f℥i
Aquæ Destillatæ q. s. f℥iv
M. ft. mist.
Sig.—One teaspoonful every three hours.
Dr. R.

Prescriptions containing tincture of guaiac are productive of much trouble. The physical incompatibility occasioned by the insolubility of the guaiac resins is an entirely separate problem and is frequently solved by the use of acacia as a suspending medium, although honey is considered more satisfactory, as the alcohol of the tincture of guaiac has a tendency to precipitate the gum from the mucilage of acacia and consequently diminishes its suspending qualities. In this particular case, a blue color reaction develops if fresh mucilage of acacia is used, which is due to the oxidase present in fresh acacia. Old mucilage of acacia on the other hand does not produce a blue color but produces a red brown color.

Guaiac also produces striking color reactions with oxidizing substances such as spirit of ethyl nitrite or with tincture of ferric chloride.

No. 46

℞ Sodii Salicylatis ℥ss
Glycerini f℥i
Olei Gaultheriæ mxx
Tincturæ Ferri Chloridi f℥ss
Syrupi f℥ii
M. ft. sol.
Sig.—One teaspoonful every four hours.
Dr. T.

The salicylates are noted for the characteristic purple or red color, produced by iron compounds. The shade and intensity of the color are dependent upon the dilution, and whether the mixture is alkaline or acid. All phenolic derivatives produce color reactions with compounds of iron, but as a rule there is no interference with the therapeutic action of the mixture. Liquor ferri salicylatis of the N. F. (page 730) is an example of an intentional combination of this kind.

Color reactions are sometimes produced in prescriptions which are in the form of powders or masses. Compound rhubarb powder is an example of a preparation in this class. When first prepared, it is of a light fawn color, but upon standing it absorbs moisture from the air, and the magnesium oxide, becoming partly hydrated, reacts with the resinous constituents of the rhubarb with the formation of a pink or red color.

No. 47

℞ Potassii Iodidi ℥v
Tincturæ Ferri Chloridi f℥ss
Aquæ Destillatæ q. s. ad f℥iv
M. ft. sol.
Sig.—One teaspoonful three times a day.
Dr. Y.

Iodine will be liberated by the oxidizing action of the ferric chloride. The color deepens gradually until eventually it is dark brown. The mixture is very irritating after it has stood for a few hours and should not be dispensed, but the physician should be notified of the condition and given an opportunity to make a change.

No. 48 ℞ Bismuthi Subnitratis ʒi
Potassii Hypophosphitis ʒss
Pepsinæ ʒi
M. ft. chart. No. XII
Sig.—One powder three times a day.
Dr. B.

In this prescription, the gradual absorption of moisture causes the gradual reduction of the bismuth compound with the development of color passing through yellow and brown to black, the latter condition indicating complete reduction to metallic bismuth.

7. **The liquefaction of solid ingredients**—This is sometimes due to the formation of a eutectic compound, in which the fusing point of the mixed ingredients is lower than that of any single one and also lower than the room temperature. An example of this kind is found in the following:

No. 49 ℞ Phenacetini gr.xv
Camphoræ gr.v
Phenylis Salicylatis gr.xv
M. ft. chart. No. X
Sig.—One every two hours.
Dr. Y.

Other examples of compounds likely to produce a similar effect when rubbed together are acetanilid, antipyrin, betanaphthol, menthol, resorcinol, thymol, phenol, etc.

The physical condition resulting from mixtures of these substances cannot be satisfactorily foretold, for it is partly dependent upon the substances themselves and partly upon the proportions in which they are mixed. For instance, one part of salol and two parts of menthol will make a dry mixture, one part of salol and one part of menthol will produce a damp powder, while two parts of salol and one part of menthol will yield a syrupy liquid. When this condition is encountered in prescription practice where powders or cachets are ordered, it is customary to add some absorbent powder to bring the mixture to the state of a dry powder before dispensing. Althea is the most satisfactory powder for this purpose.

An example in which the liquefaction is due to a different cause is seen in the following:

No. 50 ℞ Lithii Citratis gr.xxx
Sodii Phosphatis ʒi
M. ft. chart. No. X
Sig.—One powder morning and evening.
Dr. G.

In this case, the liquefaction is due to the liberation of the water of crystallization of the sodium phosphate, accompanied by chemical decomposition in which lithium phosphate and sodium citrate are produced. The remedy is to use an appropriate amount of exsiccated sodium phosphate in place of the hydrated salt.

8. **Development of poisonous constituents by chemical reaction, no visible change occurring.**

The most outstanding example of this kind is the following:

No. 51 ℞ Hydrargyri Chloridi Mitis gr.xx
Potassii Bromidi gr.xx
Sacchari Lactis gr.xx
M. ft. chart. No. X
Sig.—One every two hours until five doses have been taken.
Dr. C.

A reaction takes place between the mercurous chloride and the potassium bromide in which the mercurous chloride is decomposed with the formation of mercuric bromide and the liberation of free mercury, according to the following reaction:

$$2HgCl + 4KBr = Hg + HgBr_2 + 2KCl + 2KBr.$$

This combination should never be dispensed.

Several prescriptions have been reputed to develop toxic compounds in which investigation has shown the facts to be otherwise.

One of these is as follows:

Alleged incompatible prescription.

No. 52

℞ Liquor Hydrogenii Dioxidi
Glycerini aa f℥ii
Misce.
Sig.—Apply locally to throat with a brush.
Dr. S.

Statements have appeared in literature to the effect that this prescription developed oxalic acid by the oxidizing effect of the hydrogen peroxide upon the glycerin. This has been proved to be untrue; the mixture shows no oxalic acid even after being allowed to stand for several months under various conditions of light and temperature.

Another notable example is the following:

Alleged incompatible prescription.

No. 53

℞ Acidi Acetylsalicylici gr. xl
Quininæ Sulphatis gr. xl
M. ft. chart. No. XX
Sig.—One every two hours.
Dr. S.

It has been stated that the poisonous compound *quinotoxin* (also known as *quinicine*) is developed in combinations of quinine and acetylsalicylic acid. This possibility has been thoroughly investigated by such eminent authorities as Scoville and Sollmann, working independently with these ingredients in various proportions and in both solid and liquid combinations. The conclusions of both these investigators deny the dangerous character of this combination.

Still another instance is exemplified by the following:

No. 54

℞ Methenaminæ 8 Gm.
Sodii Biphosphatis 24 Gm.
Aquæ Destillatæ q. s. ad. 100 cc.
M. ft. sol.
Sig.—One teaspoonful every two hours.
Dr. S.

This solution upon standing has been observed to develop an odor of formaldehyde. The subject has been recently investigated by Snow, who finds negligible traces of formaldehyde when the solution is freshly prepared but less than is developed by the action of artificial gastric juice upon pure methenamine. If allowed to stand for some time, the amount of formaldehyde increases. It is imperative, therefore, that such a prescription be freshly prepared and the patient be warned against taking it if it has stood for some time.

The More Important Incompatibilities

Acacia—If alcohol or alcoholic solutions are added to a mucilage of acacia, the acacia, being insoluble, will be precipitated. Dilution with water, of either the mucilage or of the alcohol, will prevent precipitation.

Acacia mucilage is gelatinized by the solution and tincture of ferric chloride, solutions of ferric sulphate, ferric subsulphate, and iron and ammonium acetate, if they are added in concentrated form. A saturated solution of sodium borate and solution of lead subacetate likewise produce gelatinization. If the mucilage be diluted with several volumes of water or the addition of small amounts of glycerin or syrup, gelatinization may in most instances be prevented.

Acetanilid—Acetanilid possesses most of the incompatibilities of alkaloids.

When triturated with phenol, resorcinol, or thymol, a liquid or wet mass is produced; with chloral hydrate only dampness occurs.

When acetanilid is in solution with spirit of ethyl nitrite it produces a yellow color, changing to red in time. With tincture of ferric chloride a red color develops.

Acetozone—It hydrolyzes slowly when in aqueous solution, liberating oxygen. Its use depends upon this reaction and it is usually dispensed in 1 to 1000 solution. When heated or actively triturated, it decomposes.

Acetphenetidin—When mixed with chloral hydrate, it liquefies. Strong acids or alkalies decompose it. It produces a yellow color with spirit of ethyl nitrite.

Acetylsalicylic Acid (Aspirin)—It is decomposed by water and by alkalies, producing acetic and salicylic acids or their salts. Lime water causes a precipitate of calcium acetylsalicylate. Solutions of the alkaline acetates and citrates dissolve but slowly decompose it.

Adrenalin—Being a reducing agent, it is incompatible with all reducible substances.

Albumin Tannate (Tannalbin)—It is decomposed by alkalies.

Alcohol—Albumin, acacia (as has already been mentioned), and many chemical salts, in aqueous solutions, are precipitated by the addition of alcohol or alcoholic preparations, owing to their insolubility in hydroalcoholic solution.

Aloe and Aloin, in solution, are colored almost black with ferric chloride and red with spirit of ethyl nitrite, the intensity of color depending upon the degree of concentration.

Alumnol—It is reduced by contact with air and darkened. It is incompatible with salts of silver or other reducible salts.

Anethesin—It is decomposed by prolonged heating with water. Alkalies and their carbonates decompose it.

Antipyrin, triturated with crystals of phenol, produces a liquid which is odorless and is known as phenopyrin; when rubbed with chloral hydrate, a liquid is formed. A moist mass or a liquid (depending upon conditions) results from its trituration with sodium salicylate. A liquid results from its trituration with the following; acetanilid, pyrogallol, resorcinol, thymol, or ethyl carbamate. In solution with ferric chloride, a red color is developed.

Arsenic trioxide—When in solution, it is precipitated by ferric hydroxide or dialyzed iron as an insoluble arsenite.

Arsphenamine (Salvarsan, "606")—It is quickly decomposed in the air, producing arsenic compounds which are much more poisonous. Alkaline hydroxides or carbonates precipitate the base from an acid solution. It is not decomposed by acids.

Barbital (Veronal) Diethyl-barbituric Acid—When heated with sodium carbonate, ammonia is liberated. It darkens calomel when triturated with it.

Benzoates—The soluble benzoates are decomposed by strong acids when in solution, benzoic acid separating. The soluble benzoates precipitate ferric salts when in neutral or nearly neutral solutions.

Benzosol—Alkalies decompose it into guaiacol and benzoic acid.

Beta-eucaine Hydrochloride—Its aqueous solution is precipitated by alkaline hydroxides or carbonates. Mercuric chloride precipitates it from aqueous solution.

Beta-eucaine Lactate—Incompatible with alkalies and their carbonates and with most of the alkaloidal reagents.

Betanaphthol produces a damp powder or mass or a liquid when triturated with antipyrin, camphor, phenol, exalgin, menthol, or ethyl carbamate.

Betanaphthol Benzoate—It is incompatible with antipyrin, camphor, phenol, menthol, ferric chloride, and ethyl carbamate.

Bismuth Iodosubgallate (Airol)—It is incompatible with water, liberating iodine, and with mercuric chloride. It is decomposed by alkalies and acids. Moist air decomposes it, but it may be kept in glycerin, containing a little water, without decomposition.

Bismuth Tribromphenol—It is decomposed by alkalies, forming a bromide of the alkali. It may be heated to 120° C. without decomposition.

Borates—Sodium borate and other alkaline borates, being alkaline in reaction may precipitate an alkaloid from a solution of its salt. Sodium borate and other alkaline borates

precipitate salts of several of the metals when in neutral solutions, as mercuric chloride, silver nitrate, lead acetate, barium chloride, calcium chloride, alum, zinc sulphate, and ferric salts.

Bromides—The soluble bromides precipitate some of the alkaloids forming soluble compounds. This is true of strychnine, morphine, and codeine. Alkalinity of the salt may in some instances produce precipitation.

Calcium Betanaphtholsulphonate (*Asaprol*)—Light and air darken it and render it less soluble. Ferric chloride produces a blue color. It has the usual incompatibilities of calcium salts. It is decomposed and precipitated by mineral acids.

Colloidal Calomel (*Calomelol*)—It is precipitated from its aqueous suspension by acids.

Camphor, menthol, resorcinol, and *phenyl salicylate* (*salol*), when rubbed with each other in about equal proportions, or when mixed with about equal weights of phenol, chloral hydrate, betanaphthol, pyrogallol, thymol, or ethyl carbamate (urethane) will produce a soft mass or liquid.

Carbonates of the alkalies precipitate many alkaloids from solutions of their salts.

Chloralformamide (*Chloralamide*)—When mixed with antipyrin or menthol, it liquefies. Water or alkalies decompose it into chloral hydrate and formalmide. It reduces silver nitrate.

Chlorates—When triturated or heated with the following substances may cause an explosion: sulphur, tannic acid, sulphides, sulphites, cyanides, hyposulphites, hypophosphites, nitrites, iodine, phenol, charcoal, sugar, honey, glycerin, and many other oxidizable substances.

Chloretone (*Acetone-chloroform*)—Weak acids or alkalies decompose it. It liquefies when triturated with an equal weight of phenol, menthol, antipyrin, euphorin, or exalgin.

Chromates and Dichromates—The soluble chromates and dichromates precipitate salts of lead, silver, mercury, and bismuth when in aqueous solution.

Chromium trioxide—When added to strong alcohol, glycerin, ether, or volatile oils, or other substances that may be easily oxidized, is apt to cause fire or explosion.

Colloidal Silver (*Collargol, Cargentos*)—Continued boiling causes precipitation. It is not precipitated by alkalies. Saturated solutions of sodium chloride usually act as a precipitant, but not for cargentos, which is said to contain some casein. They should not be exposed to light or air longer than necessary, as they have the usual characteristics of silver salts.

Creosote in alcoholic solution produces a bluish-green color with ferric chloride in alcoholic solution.

Creosote Carbonate (*Cresolal*)—It is decomposed by alkaline hydroxides.

Cyanides—The alkaline cyanides may produce precipitates of an alkaloidal character from solutions of their salts.

Diuretin (*Sodio-theobromine Salicylate*), when triturated with phenol or chloral hydrate, forms a liquid.

Epicarin. (*Betanaphtholhydroxytoluic Acid*)—Exposure to air colors it red. Alkaline hydroxides and carbonates combine with it, forming in most cases, insoluble salts.

Epinephrine (*Adrenalin, Suprarenalin, Adnephrin, Supracapsulin*)—It is readily oxidized, becoming inert and of a pink to red color. It quickly reduces gold, silver, and mercuric salts. It is precipitated from acid solution by alkali hydroxides or carbonates. Iodine produces a pink color.

On the addition of ferric chloride to solution of epinephrine, an emerald-green color develops. It produces a pink color when combined with iodine. It reduces silver and gold salts in solution, producing a red liquid.

Ethyl Carbamate (*Urethane*)—Strong alkali liberates ammonia. With iodine and an alkali hydroxide or carbonate it yields iodoform.

Ethylene Diamine—It is strongly alkaline and has the same general incompatibilities as sodium hydroxide, decomposing many metallic and alkaloidal salts.

Ethylmorphine Hydrochloride (*Dionin*)—It is precipitated by the usual alkaloidal reagents and by strong alkalies and carbonates.

Europhen—It is incompatible with starch, the metallic oxides, mercuric salts, and the alkaline hydroxides and carbonates. It should not be exposed to light, heat, or damp air.

Exalgin (*Methyl Acetanilide*) produces a liquid or soft mass under conditions similar to those of camphor.

Ferropyrine—It is decomposed by alkaline hydroxides, carbonates, and bicarbonates.

Gallogen (*Ellagic Acid*)—It shows the general incompatibilities of the tannins with iron salts and gelatin and is decomposed by alkalies.

Gambir (*Catechu*), as well as many other substances containing large amounts of tannin, as *kino, krameria, hematoxylon, geranium,* and *oak bark,* produce precipitates similar to those of tannic acid.

Glycerin—When rubbed with dry oxidizing agents, as potassium permanganate, potassium chlorate, etc., it is apt to cause an explosion.

Gold and Sodium Chloride is a general alkaloidal precipitant, producing insoluble double compounds with most of the alkaloids.

Guaiac—The addition of oxidizing substances to an alcoholic solution of fresh guaiac resin will rapidly develop a blue color, changing to green and red; nitric acid, chromium trioxide, chlorine, potassium ferricyanide, potassium permanganate, ferric chloride, gold chloride, spirit of ethyl nitrite and others, will produce this effect. Mucilage of acacia, when fresh, also develops a blue color.

Guaiacol causes a similar color change with ferric chloride (see Creosote).

Guaiamar (*Glyceryl Guaiacolate*)—It is decomposed by alkali hydroxides and carbonates and by strong acids.

Hedonal—It is decomposed by alkaline hydroxides, carbonates, and bicarbonates, forming methylpropylcarbinol, ammonia, and carbon dioxide.

Holocaine Hydrochloride—It is precipitated from solution by most of the alkaloidal reagents. The alkali hydroxides or carbonates precipitate it from aqueous solution.

Hydriodic acid and the soluble iodides produce precipitates in aqueous solutions of lead and silver salts and with mercurous and mercuric compounds, the precipitate usually being soluble in an excess of either substance.

Hydrobromic acid and the soluble bromides produce precipitates with soluble lead, silver, and mercurous salts. The precipitate formed with mercuric compounds is soluble in an excess of either salt.

Hydrochloric acid and the soluble chlorides precipitate the soluble lead, silver, and mercurous salts, from their solutions, as chlorides.

Hydrochloric acid gives a red to violet color with an alcoholic solution of myrrh.

Hydrochloric acid—When added to a chlorate liberates chlorine (see Liquor Chlori Compositus N. F.).

Hydroxides—The fixed alkali hydroxides as well as ammonia water precipitate free alkaloids from solutions of almost all of the salts of alkaloids.

Hypophosphites—The alkali hypophosphites when added to solutions of ferric salts produce a precipitate of ferric hypophosphite, which is soluble in the presence of sufficient alkaline citrate.

Ichthargan (*Silver Ichthyol*)—It is precipitated by soluble chlorides. It should not be exposed to light.

Ichthyol—It is incompatible with acid and alkaline solutions, also with solutions of the carbonates and iodides, and with mercuric chloride and most alkaloidal salts. The salts of alkaloids are precipitated from solution by ichthyol, in a resin-like mass. Heat causes ichthyol to separate from a suppository mass.

Inorganic Acids, as well as *organic acids*, with the exception of hydrocyanic acid and hydrosulphuric acid (hydrogen sulphide), liberate carbon dioxide from carbonates or bicarbonates when in solution; carbonates are also decomposed by many of the acid salts of the metals.

Iodides—The soluble iodides form insoluble compounds with many alkaloids; the combination with strychnine is especially dangerous. Alkalinity of the salt may sometimes account for the precipitation.

Iodine is a precipitant for most of the salts of alkaloids. Iodine may combine with oil of turpentine with sufficient force to produce an explosion.

Iodo-casein—It is decomposed by alkalies.

Iodophenacetin (*Iodophenin*)—It is decomposed by water, iodine being liberated. Any substance having a strong affinity for iodine, such as the alkalies, will decompose it.

Lead Acetate is precipitated from solution by the soluble carbonates, sodium borate, soluble sulphates, bromides, iodides, chromates, sodium phosphate, and tannic acid.

Lennigallol (*Pyrogallol Triacetate*)—It is incompatible with alkalies, strong acids, and oxidizing agents.

Lycetol (*Dimethyl-piperazine Tartrate*)—It is incompatible with alkalies which liberate the insoluble base.

Lysidin (*Ethylene-ethenylamidine*)—Its incompatibilities are similar to ethylenediamine.

Mercuric Chloride (*Corrosive Sublimate*)—It is a general alkaloidal precipitant, producing insoluble compounds. Corrosive sublimate is reduced to calomel and then to metallic mercury by metallic zinc, copper, or iron when water is present. In alkaline mixtures the reduction occurs in the presence of the soluble arsenites, antimony and potassium tartrate, ferrous salts, and is also caused by light.

Mercuric Chloride is precipitated when in solution by the fixed alkaline hydroxides. The precipitate, if the alkali is in excess, is yellow mercuric oxide, as in the case of "yellow wash", in which lime water is the precipitant. Ammonia water and ammonium carbonate precipitate ammoniated mercury when added to solution of corrosive sublimate. It is also precipitated by potassium or sodium carbonate or bicarbonate and by sodium borate.

Mercuric Iodide (*red*) is reduced under conditions similar to those of corrosive mercuric chloride. Its incompatibilities are similar to those of corrosive mercuric chloride. The incompatibilities of red mercuric oxide in the ointment are similar to those of the yellow oxide.

Mercuric Oxide (*yellow*)—The ointment darkens if kept for some time, due to reduction to other oxides or metallic mercury. Reducing agents rubbed with it, will also produce this effect. Yellow mercuric oxide is reduced by cocaine hydrochloride, forming mercuric chloride.

Mercuric Potassium Iodide (Mayer's reagent) is a well-known alkaloidal precipitant, producing insoluble combinations with almost all of the alkaloids or their salts.

Mercuric Salicylate—Sodium hydroxides or sodium carbonate decompose it. It is rendered soluble by chlorides, bromides, iodides, and sodium salicylate.

Mercurous Chloride (*Calomel*)—A precipitate of black mercurous oxide results from the addition of potassium, sodium, or calcium hydroxides to calomel. The well-known "black wash" is an example of this reaction. Calomel is reduced to metallic mercury by nitrous compounds, as spirit of ethyl nitrite, and by the hypophosphites and in alkaline mixtures by arsenites and antimony and potassium tartrate.

Mercurous Iodide (*yellow*)—Its incompatibilities are similar to those of mild mercurous chloride. Yellow mercurous iodide is reduced to metallic mercury under conditions similar to those of calomel.

Colloidal Mercury—It is decomposed by acids, hydroxides, and the salts of many metals. It does not precipitate albumin. It reduces mercuric chloride.

Methenamine (*Hexamethylenamine, Urotropin, Formin*)—Mercuric chloride or tannic acid precipitates it from an aqueous solution. It is decomposed by hot water. Sodium salicylate, phosphate, or benzoate do not precipitate it from solution. It liquefies when rubbed with lithium carbonate or benzoate, sodium or phenyl salicylate, sodium benzoate or antipyrin. It liberates acetic acid from aspirin, followed by formaldehyde.

Methylthionine Hydrochloride (*Methylene Blue*) is precipitated from solution by potassium iodide or potassium dichromate.

Neoarsphenamine (*Neosalvarsan*)—It is quickly decomposed when in contact with the air, producing dangerously poisonous compounds. Mineral acids decompose it.

Nitric Acid—When mixed with strong sulphuric acid and glycerin it produces nitroglycerin, a powerful explosive; it also produces explosive compounds with cotton, or other forms of cellulose, and if mixed when concentrated with silver or mercuric nitrate and alcohol, explosive fulminate will be formed.

Orthoform, New—It is decomposed by heating with water. Ferric chloride produces a violet to black color. It is dissolved but decomposed by solutions of the alkali hydroxides and carbonates. It reduces silver nitrate and other oxidizable salts.

Pancreatic Ferments (*Diazyme Essence and Glycerole, Holadin, Panase, Pancreon, Trypsin, etc.*)—They are all incompatible with strong alcohol, acids, and alkalies. They readily lose their activity when in dilute solution.

Peroxides (*Dioxides*)—The metallic peroxides liberate oxygen when in aqueous solution. Acids liberate hydrogen dioxide. They readily oxidize organic substances or salts which are readily reduced.

Phenacetin (Acetphenetidin), when triturated with phenol or chloral hydrate will produce a liquid.

Phenocoll Hydrochloride—It is decomposed by the soluble hydroxides or carbonates precipitating the base. It is precipitated by most alkaloidal reagents. It reduces gold or silver salts.

Phenocoll Salicylate (*Salocoll*)—It has the usual incompatibilities of the salicylates. It liquefies when triturated with chloral hydrate.

Phenol causes a gelatinous precipitate when added to solutions of gelatin, albumin, etc.

Phenyl Salicylate in alcoholic solution produces a violet color with ferric chloride if the latter is in dilute solution.

Piperazine—Being strongly alkaline, it is incompatible with acetanilid, acetphenetidin, most alkaloidal salts, nitrites, metallic salts generally, and with picric and tannic acids. It reduces silver nitrate and other readily oxidizable salts. It produces a liquid or soft mass when triturated with chloral hydrate, acetanilid, phenol, acetphenetidin, and antipyrin.

Potassium Cyanide, when rubbed with potassium nitrate or chlorate is apt to produce a violent explosion.

Potassium Dichromate will precipitate many alkaloidal salts, as morphine, strychnine, quinine, atropine, codeine, and hydrastine, if their solutions are sufficiently concentrated.

Potassium Hypophosphite and other hypophosphites when rubbed with calomel cause it to turn dark at once from reduction to metallic mercury. Calomel is also said to be reduced in the presence of moisture by cocaine, pilocarpine, antipyrin (especially in the presence of sugar), cane sugar, and milk sugar. It has been suggested that some mercuric chloride is formed.

Potassium Nitrate produces readily oxidizable compounds, which may explode, if mixed with sulphur, charcoal, phosphorous, sugar, or sulphides.

Potassium Permanganate—When triturated with readily oxidizable substances, as sulphur, the hypophosphites, charcoal, sugar, glycerin, etc., is apt to occasion an explosion.

Potassium or Sodium Carbonates precipitate many soluble salts, producing insoluble carbonates, hydroxides, or oxides. Soluble salts of the following are so precipitated: silver, mercurous and mercuric compounds, ferrous and ferric iron, manganese, barium, strontium calcium, tin, aluminum, chromium, antimony, lead, nickel, copper, zinc, and magnesium.

Pyramidon (*Dimethylaminoantipyrin*)—Its incompatibilities are similar to those of antipyrin; oxidizing solutions and acacia produce colored solutions.

Quinine and Urea Hydrochloride—It is decomposed by the soluble alkaline hydroxides, alkaloidal quinine being precipitated.

Quinine Ethylcarbonate (*Euquinine*)—Its special values depend upon its being tasteless, but acids decompose it and develop a bitter taste.

Resorcinol—Solutions of resorcinol are colored violet by ferric chloride and by chlorinated lime or soda, the latter changing to yellow. Spirit of ethyl nitrite produces a dark red color.

Salicylates—The soluble salicylates, when added to an aqueous solution of quinine sulphate, produce insoluble quinine salicylate.

The mineral acids and some organic acids liberate the but slightly soluble salicylic acid when added to solutions of the soluble salicylates.

Salicylic Acid and Salicylates, including *Oil of Wintergreen*, produce a precipitate with ferric salts if in nearly neutral solutions, also produce a deep blue to violet-red color; the alkaline acetates and citrates, if present in sufficient amount, will prevent this precipitate.

Salicylic acid produces a damp powder or a liquid when rubbed with exalgin, lead acetate, sodium phosphate, or ethyl carbamate.

Saliformin (*Hexamethylenamine Salicylate*)—It is decomposed by alkaline hydroxides, carbonates, and by strong acids. It shows the general incompatibilities of the salicylates.

Salipyrine (*Antipyrin Salicylate*)—It is incompatible with acids, alkalies, and tannins.

Salophen—The alkaline hydroxides decompose it.

Saloquinine (*Quinine Salicylic Ester*)—It is precipitated from acid solution by most alkaloidal reagents. Ferric chloride colors its alcoholic solution reddish-violet.

Sidonal (*Piperazine Quinate*)—It shows the general incompatibilities of alkaloids.

Silver Casein (*Argonin*)—Its aqueous solution is precipitated by acids, but it is soluble in the presence of alkalies and sodium chloride. It is not effected by the usual silver reagents. It is precipitated by lead acetate, mercuric chloride, ferric chloride, zinc sulphate, phenol, alum, and tannic acid.

Silver Nitrate, with many organic substances, as glucose, aromatic oils, tartrate, creosote, etc., is oxidized, being changed to metallic silver, oftentimes with explosive violence.

Silver Nitrate is reduced to metallic silver by metallic zinc, copper, tin, mercury, or lead, by the soluble hypophosphites and sulphites, and in alkaline solution by arsenites, manganous and antimonous salts, and also by ferrous sulphate.

Silver Nitrate in aqueous solution is precipitated by the alkaline hydroxides, the alkali carbonates, the soluble chlorides, bromides, iodides, cyanides, sodium phosphate, chromates, soluble arsenites and arsenates, and by potassium permanganate if the solution is not too dilute. Tannic acid and the soluble citrates and salicylates also precipitate solutions of silver nitrate.

Silver Oxide produces an explosive mixture with many substances, as sulphur, tannic acid, creosote, and many organic substances.

Silver Protein (*Protargol*)—It is precipitated by most metallic salts, also by picric acid. It is decomposed by light and air and should be protected. Cocaine hydrochloride causes a precipitate which may be prevented by the addition of boric acid.

Silver Vitellin (*Argyrol*)—It yields a slight precipitate of silver chloride with sodium chloride or hydrochloric acid. It is incompatible with acids, most of the neutral or acid salts, and with alcohol, forming a precipitate. Mercuric chloride and ferric chloride decolorize it and produce a white precipitate. It is not precipitated by albumin or alkalies.

Sodium Benzoate—Quinine sulphate when not in too dilute solution is precipitated by sodium benzoate.

Sodium Thiosulphate (*Hyposulphite*) is decomposed by acids, when in aqueous solution; sulphur being precipitated and sulphur dioxide liberated.

Solution of Arsenous and Mercuric Iodides (Donovan's solution) is a general alkaloidal precipitant.

Solution of Hydrogen Dioxide mixed with Phenol darkens within a few hours, the phenol being oxidized. Solution of hydrogen dioxide reduces potassium permanganate and is itself decomposed; if sulphuric acid is present, oxygen is freely liberated. It is also decomposed

by the following, yielding oxygen; some organic substances, manganese dioxide, sodium sulphate, potassium bromide, potassium chloride, and charcoal.

Solution of Lead Subacetate (Goulard's extract), and *Lead Acetate* precipitate most of the alkaloids as well as other plant principles from their aqueous solution, forming an insoluble compound.

Solution of Potassium Arsenite (Fowler's solution).—The solution being alkaline from an excess of potassium bicarbonate may precipitate alkaloids.

Starch—Starch paste is colored blue by free iodine, the depth of color depending upon the concentration. This color is dissipated by heat, but returns upon cooling.

Stovaine—It is precipitated by the usual alkaloidal reagents. Even weak alkali decomposes it. Heat, even a boiling temperature, does not decompose it.

Styracol (*Guaiacol Cinnamate*)—It is decomposed by alkaline hydroxides.

Sublamine (*Mercuric Sulphate, Ethylenediamine*)—It should not be exposed to the air. It is incompatible with sodium chloride.

Sulphonal, when triturated with chloral hydrate produces a liquid.

Sulphonethylmethane (*Trional*)—It forms a soft mass when triturated with thymol, urethane, phenyl salicylate, and chloral hydrate.

Sulphonmethane (*Sulphonal*)—It is very stable, not being decomposed by acids, alkalies, or oxidizing agents. Rubbed with chloral hydrate, it liquefies.

Sulphuric Acid—When mixed with chlorates it produces an explosion.

Sulphuric Acid and Soluble Sulphates precipitate soluble salts of lead, barium, strontium, and calcium when in sufficiently concentrated solution.

Tannic Acid will produce a precipitate when added to solutions of gelatin, albumin, gluten, or starch. Tannic acid produces a dark blue-black color with solutions of most ferric salts, the depth of color depending upon the degree of concentration. The color of a solution of ferric phosphate is not changed by tannic acid. With ferrous salts, if pure, a white, gelatinous precipitate is first produced, which rapidly becomes blue through oxidation to ferric salts. Usually, the ferric salt is present and a blue colored precipitate is produced at once.

Tannic acid forms insoluble compounds with most of the alkaloids, and some glucosides and other plant principles.

Tannigen (*Diacetyl Tannin*)—It is decomposed by alkalies and salts of iron. It should not be exposed to heat or moisture.

Tannopin—It is decomposed by alkalies.

Theobromine Sodio-acetate—It is decomposed by most of the alkaloidal reagents, and by carbonated beverages, acids, and saccharine and mucilaginous liquids.

Theobromine Sodio-salicylate (*Diuretin*)—It is decomposed by acids, when in solution, theobromine and salicylic acid both being precipitated. It reduces salts of silver and mercury. Being alkaline, it shows the general incompatibilities of alkalies, also of theobromine and of salicylates.

Thigenol (*Sodium Sulpho-oleate*)—It is incompatible with mineral acids and also with acetic acid.

Trional, when triturated with chloral hydrate or phenyl salicylate, produces a liquid.

Tropacocaine Hydrochloride—It shows the general incompatibilities of alkaloids.

Validol (*Methyl Valerate*)—It is decomposed by alkalies.

Water—When alcohol has been used as the solvent for many substances, such as free alkaloids, glucosides, neutral or bitter principles, salicylic or benzoic acids, volatile oils, resins, oleoresins, balsams, or camphors, the addition of water or aqueous liquids to the alcoholic solutions will cause complete or partial separation of the dissolved substances, owing to their insolubility in hydro-alcoholic liquids; the amount of separation depending upon the degree of dilution.

CHAPTER XCVIII

EXTEMPORANEOUS SOLUTIONS AND MIXTURES

Official liquid preparations have already been considered in Part III, therefore this chapter will be confined to the extemporaneous compounding of liquids. It will soon be realized by the student that this branch of practical pharmacy involves some of the most intricate questions of physical and chemical science. The knowledge which he has heretofore acquired of the solubilities of solids in various solvents, simple and compound, the miscibility of liquids with one another, chemical decompositions, reactions between acid and alkaline salts, precipitation through single and double decomposition, etc., will often be of great service. This, coupled with practical experience, and with the exercise of original ingenuity, must be depended upon to meet the perplexing questions which continually arise at the prescription counter and in the preparation of other medicinal products.

Extemporaneous liquid preparations may be classified as follows: 1. *Solutions*, by which are meant liquid preparations containing dissolved solid substances. 2. *Mixtures*, liquids in which the solution is but partial, insoluble particles being held in suspension. 3. *Emulsions*, preparations containing oily or resinous substances mixed with water, through the medium of an emulsifying agent, to form homogeneous liquids. These will be considered *seriatim*, the latter being taken up in a separate chapter.

SOLUTIONS

The methods generally employed in making official and other solutions have been discussed in the preceding chapters, and it must be presumed that the reader is familiar with them. Most of the difficulties encountered in effecting solutions required by prescriptions arise from the lack of knowledge, on the part of prescribers, of the solubilities and of the physical and chemical characteristics of the medicinal agents which they order to be compounded. It is necessary, therefore, for the pharmacist to be well grounded in these particulars. It is also important that the pharmacist possess a broad knowledge of the therapeutics of drugs and chemicals, lest the addition of some apparently inert substance, intended to improve the preparation pharmaceutically, be injurious therapeutically.

Incompatibility—The subject of incompatibility must be thoroughly comprehended and, inasmuch as it occurs in solid preparations as well as liquids and is of far reaching importance, it has been considered at length and under a separate head (see Chapter XCVII).

COMPOUNDING EXTEMPORANEOUS SOLUTIONS

Use of Heat in Compounding Extemporaneous Solutions—As a general rule, it is not advantageous to aid the solution of a solid by heating it in contact with the solvent, except where the quantity of liquid is known to be in excess of what is required to form a solution, and such a liquid should never be dispensed until it has become cool. If the solid be crystalline, the excess will surely separate in crystals when the liquid cools, and the patient will become uneasy and suspicious, fearing lest some mistake has occurred. It frequently happens that more of a solid has been prescribed than can be dissolved in the amount of liquid desired; indeed, it is entirely too much to expect that every

practitioner should carry in his mind the exact solubilities of all the solids that he prescribes in the respective liquids in which he may wish to dissolve them. This gives the pharmacist another opportunity to use his knowledge and judgment, and the problem

When to filter is oftentimes perplexing, although one simple rule should govern the practice: *A solution may be filtered and dispensed as a transparent liquid when the removal of the excess does not interfere with the medicinal properties and action of the medicine, nor conflict with the obvious intention of the prescriber.*

Solutions of potassium chlorate, to be used as gargles, are good illustrations:

℞ Potassii Chlorat. ℥iv
Phenolis gtt. xv
Infus. Salviæ f℥vi.
Misce.
Sig.—Use as a gargle.

The quantity of salt is about double the amount necessary, and, as the solution is intended as a gargle to inflamed surfaces, the undissolved particles of potassium chlorate would probably act as irritants. They can be of no use in the solution if it is to be used directly as a gargle, and in this case filtration is admissible. On the other hand if the physician has directed its dilution with water before gargling, the potassium chlorate might dissolve. It is necessary to ascertain the intent of the doctor before acting in such a case.

The following prescription should not be filtered, and the pharmacist is compelled to rely solely upon his judgment and knowledge of the therapeutic action and properties of the ingredients:

℞ Magnesiæ Pond. ℥iss
Mass. Hydrarg. ℥ss
Sacch. Alb. ℥i
Sp. Ammon. Arom. f℥ii
Aq. Menth. Pip. f℥ii
Liq. Calc. Hydrox. f℥iii
Sig.—A tablespoonful every two hours.

The reasoning here would be direct and simple. The prescriber evidently intends this to be an alkaline cholagogue mixture, although the directions to "shake the bottle" have been omitted. Heavy magnesia and blue mass are both practically insoluble in the liquids, and if they are filtered or strained out the mixture is deprived of its most important constituents. It should be dispensed as a mixture and a "shake" label used.

Prescriptions containing chemicals in solution should be freed from minute particles of foreign matter so often present in powdered chemicals. This is particularly necessary when the liquid is intended as an eye wash or as eye drops. Aqueous liquids may be filtered, preferably through a "hard filter" in a small Buchner funnel (see Fig. 315). The ordinary filter paper does not readily free a solution from filaments, as these often come from the paper. A small pledget of absorbent cotton placed in the throat of the funnel before inserting the filter paper will be found of value as it collects the filaments from the filter. It is sometimes necessary to return the filtrate to the filter, repeatedly, before the solution is absolutely clear, unless a "hard filter" is used. Viscid liquids should be strained through fine-mesh gauze, which should be kept at the prescription counter cut into small squares to fit the funnel pictured in Fig. 285.

Aids in Effecting Solution—The use of solvents which are not directed in the prescription, for the purpose of effecting the complete solution of the ingre-

dients, requires probably the greatest amount of good judgment. The practice is one which is liable to great abuse, and a strict rule should be enforced that no addition is admissible under any circumstances except one which is absolutely demanded by necessity and which will in nowise impair the therapeutic effect. The prescriber should have reason to place implicit reliance upon the compounder and feel satisfied that the patient has received exactly what was ordered. Incompatible prescription No. 3 (see page 1630) is a good illustration of a case requiring an addition; a physician prescribed it as an application for dry, excoriated nipples. It is as follows:

℞ Phenol. Liq. f℥ii
Aquæ q. s. ad. f℥i
M. ft. sol.
Sig.—Solution of Carbolic Acid. Use with a camel's hair brush.

Dr. W.

Phenol or carbolic acid is not soluble in water in the proportions named, only about 1 part dissolving in 15 parts of water. The pharmacist dispensed the prescription just as it was written, with the excess of phenol in the bottom of the bottle. The patient inserted the camel's hair brush and permitted it to remain in the bottle, so that it reached the bottom and became saturated with the undissolved phenol. The application produced severe pain and alleged serious injury and became the ground for a civil suit for damages against the pharmacist, brought by the patient. If the pharmacist had added a small quantity of glycerin, all difficulty would have been avoided, and he could then have dispensed a perfect solution. It is hardly necessary to say that the physician should not have omitted prescribing the glycerin; but, as he failed to do so, it was the duty of a careful pharmacist to inform him of the facts, or, failing to find him, to supply the deficiency and subsequently notify him of the addition.

The order to be followed in mixing the ingredients is frequently very important, and many prescriptions which at first sight appear to contain incompatibles will be easily compounded by observing the proper order in mixing. As has been shown, precipitation frequently takes place when one liquid or solution is added to another, and this annoyance is much more liable to occur when concentrated solutions are brought together. Hence the dilution of the solution is recommended as one method of avoiding precipitation. An illustration is afforded in the following:

℞ Liq. Ammon. Acet. f℥iv
Acidi Acetici f℥i
Tr. Ferr. Chlor. f℥ss
Glycerini f℥ss
Mucil. Acac. ad. f℥viii
M. ft. sol.
Sig.—A teaspoonful every three hours.

If the tincture of ferric chloride is mixed with the acetic acid and glycerin and then added to the solution of ammonium acetate, and this solution mixed with the mucilage of acacia, no gelatinization will occur; but if the tincture of ferric chloride is first added to the mucilage, undiluted, a gelatinous precipitate will form, and, although the subsequent addition of the other ingredients will, in time, dissolve the precipitate, this time could be saved by following the proper order. See also incompatible prescription No. 29, page 1638.

The following rule should be insisted upon: *Whenever a difference in the appearance of a liquid is produced by a variation in the order of mixing, a memorandum noting the order, should be made upon the prescription at the time it is compounded, so that in case of renewal the same order may be followed.*

MIXTURES

Mixtures, properly speaking, are aqueous preparations intended for internal administration, containing some insoluble substances, frequently with viscid or sweet liquids to aid in suspending them. The official mixtures have been already noticed (see page 291). The term mixture, however, is indiscriminately applied in extemporaneous pharmacy and in prescriptions to aqueous solutions of all kinds. For instance, solution of potassium citrate is frequently termed "fever mixture", although it is a perfectly transparent solution.

CHAPTER XCIX

EMULSIONS AND EMULSIFICATIONS

An emulsion is a system in which there are two liquid phases, one of which is dispersed in the other as globules or droplets. The liquid which is broken up into globules is called the *dispersed phase* while the liquid surrounding the globules is called the *dispersing* (or *dispersion*) *medium*, or the *continuous phase*. The two liquids, which are immiscible or nearly so are sometimes referred to as the *internal phase* and the *external phase*, respectively.

For any two immiscible liquids such as A and B, two types of emulsions are theoretically possible, according to whether A is dispersed in B or B dispersed in A. Oil and water are typical liquids of which emulsions may be formed, therefore there may be *oil-in-water emulsions*, which is the type most commonly seen, exemplified by cod liver oil emulsion, or *water-in-oil emulsions*, exemplified by lime liniment or Carron oil.

When oil and water are shaken violently together an emulsion is temporarily formed, but upon allowing the system to stand, the globules coalesce and the liquids quickly separate, sometimes with a slight intermediate layer of emulsified material which requires a longer time for separation.

In order to prepare stable emulsions of either type a third substance is necessary, in addition to the two liquids. This third substance is known as the *emulsifier* or *emulsifying agent*.

In the cod liver oil emulsion previously referred to, the emulsifying agent is gum. In the lime liniment the emulsifying agent is the calcium soap formed in small amount by interaction between the lime water and the linseed oil.

Emulsifying agents are usually colloidal in character. Gums have long been used in pharmacy as emulsifying agents; egg yolk, and saponin, from quillaja, have also been used.

Gelatin, albumen, casein, agar, soap, and starch all have emulsifying properties in certain types of combinations. The efficiency of alkalies as emulsifying agents is dependent upon the extemporaneous formation of a soap when a saponifiable oil constitutes one phase of the system. Emulsification is a phenomenon of surface tension. In the subdivision of a substance into the minute globules necessary for the production of an emulsion, a large amount of surface energy is produced. Emulsifying agents are substances which lower the surface tension and thereby promote the stability of such dispersions.

It has been found also that substances which are themselves insoluble (thereby differing from all of the emulsifying agents named) are efficient emulsifying agents in certain combinations. Clays, silica, finely divided carbon, calcium sulphate, chalk, and even insoluble basic salts of certain metals have been used effectively in preparing emulsions of great stability.

The theory of emulsification is based upon three factors. First, the decreasing (by the agency of the emulsifying agent) of the interfacial surface tension so as to prevent ready coalescence of the globules. Second, the purely mechanical action of the emulsifying agent in keeping the globules apart by the formation of a film enclosing each one. Third, the conferring of an electric charge, possibly by ionic adsorption, which causes repulsion of the globules.

Emulsification is influenced by the amount of emulsifying agent; the ease of its adsorption at the interfacial layer, and the nature of the ionic dissociation and adsorption by the resultant film.

A marked increase in viscosity accompanies emulsification. Other things being equal the smaller the globules of the dispersed phase and the more thorough the emulsification, the higher the viscosity will be. This is the principle upon which homogenization is based. "Homogenized" milk or cream is milk or cream which has been subjected to enormous pressure while being forced through plates or disks, containing minute orifices, in a machine called a "homogenizer" or "viscolizer" (see Fig. 596). The purpose is to subdivide the fat globules so that they are very much more minute than in the natural product. The effect of homogenizing milk or cream is to produce a perfectly homogeneous liquid, which does not separate into layers by the influence of gravitation (no perceptible cream line will form upon homogenized milk), and in which the viscosity is at the same time greatly increased. Homogenized cream can neither be satisfactorily whipped nor churned to make butter. It finds its greatest commercial use in the ice cream industry.

The size of the globules in properly made emulsions is from 5 to 20 μ. By homogenization the size of the particles may be reduced to 1 or 2 μ.

The stability of emulsions is influenced by the size of the globules of the dispersed phase, *i.e.*, the thoroughness of the emulsification, and also by the presence or absence of certain electrolytes which have the property of breaking emulsions when present in certain concentration. This explains the separation of the oils in such preparations when chemical salts are added in dispensing. (See Chapter on Colloids for the influence of electrolytes upon colloidal dispersions.)

FIG. 590

Making an emulsion

The viscosity of emulsions depends upon the relative proportions of the two phases as well as the type of the emulsion. Some commercial emulsions are too thick to pour—example, mayonnaise, which is an oil-in-water emulsion usually containing about 90 per cent of oil; others are solid—example, butter, which is a water-in-oil emulsion containing less than 20 per cent of water.

Emulsification is therefore the art or practice of effecting the dispersion of one liquid in another in more or less permanent form, usually with the aid of a third substance known as the emulsifying agent.

The favorite emulsifying agent in pharmacy, from many years of empiric practice, is acacia. Drummond, Zilva, and Coward (J. Soc. Chem. Ind. 43, 236-8T (1924) found, however, that acacia and Irish moss emulsions of cod liver oil were reduced 50 per cent in vitamine A activity, probably due to oxidases, while tragacanth emulsions showed no appreciable deterioration.

Emulsification on the small scale is usually accomplished by the aid of the mortar and pestle, a shallow porcelain mortar being preferred (see Fig. 590). Some types of emulsions, notably those of volatile oils and liquids of low viscosity may be made by simple agitation in a bottle or other suitable container as in the official Emulsion of Oil of Turpentine, page 288.

On the larger scale emulsifying apparatus is employed. The general principle involved in all forms of such apparatus is the employment of stirrers, beaters, baffle plates, screw propellors or injectors for the effecting of the thorough agitation of the liquids in the presence of the emulsifying agent (see Figs. 562 to 567).

Emulsions on the large scale are usually made in separate batches, but continuous flow emulsifiers are now being introduced.

A distinction should here be made between the phenomenon of "breaking" or "cracking" of the emulsion, due to the coalescence of the dispersed phase, and that of "creaming" which is caused by the emulsified oil stratum separating because of differences in specific gravity. The latter type of separation is not a serious defect since shaking restores the uniformity of the mixture.

Emulsions are sometimes classified as *natural* or *prepared*. Milky plant juices—as rubber latex, milk, and yolk of egg are examples of natural emulsions while the pharmaceutical emulsions belong to the latter class.

Gum resin emulsions, as prepared from asafetida, myrrh, etc., are misnomers. They are not really emulsions but are colloidal suspensions.

Seed emulsions, as made by triturating oily seeds such as almond, are examples of prepared emulsions where no added emulsifying agent is required, the factors favorable for emulsification being found in the drug itself.

When called upon to prepare emulsions on the small scale, either extemporaneously or for stock, the pharmacist has a choice of two methods, both originally European and called the *English* and the *Continental methods* respectively. Both are equally useful and should be employed according to circumstances.

1. **The English Method**—In this mode of making emulsions the emulsifying agent, consisting of mucilage, yolk of egg, etc., is first placed in a dry mortar, and small quantities of the oil and water are gradually and alternately added at intervals. In this method the emulsifying agent is always aqueous. The pestle is rapidly and lightly rotated in the direction of the arrows (see Fig. 590), with the effect of dashing the oil into globules, which are at once enveloped by the viscid emulsifying agent. If the oil or water is added too rapidly at the beginning, or the mucilage has not been thick enough, the accident of *"cracking"* the emulsion occurs. This may be known by the "pearly" appearance assumed by the mixture, and on close examination the globules of unenveloped oil may be seen floating about. If the amount of water added, as the emulsification proceeds, is not sufficient, an excessive amount of air is incorporated and the mixture becomes too thick to pour freely and will not mix with water. The aim throughout should be to retain a thick creamy liquid which flows freely and yet is of sufficient viscosity to entangle the droplets of oil. If each stage of the process is successful, the emulsion presents, a smooth, opaque, glistening appearance like cream. Success depends largely upon the care exercised in forming the nucleus at the beginning, and this, therefore, should not be too hastily made. When an emulsion is "cracked", it need not be thrown away. It may be restored by placing an additional quantity of mucilage in a clean mortar and gradually adding the "cracked" emulsion to it, triturating after each addition.

The English method of making emulsions is the best to use in general prescription practice, where the proportions of gum, oily or resinous liquids, and water must necessarily vary. A thorough understanding of the application of the English emulsification method is essential for the dispensing and the manufacturing pharmacist.

Aqueous emulsifying agents require this process—such substances as glycerite of egg and mucilage of chondrus—and it is the only method applicable to many prescriptions. A typical formula is appended:

℞ Olei Morrhuæ f℥ii
Pulv. Acaciæ ℥ss
Aquæ q. s. ft. f℥iv.

Place the acacia, which should not be finely powdered, but granulated, in a mortar with one fluidounce of water. (Always add sufficient water at the beginning to dissolve the acacia, otherwise it forms a tough mass which it is difficult to dissolve.) This should be triturated until the mucilage is perfectly smooth and free from lumps. The oil should be added at first in quantities not greater than half a fluidrachm at a time, stirring rapidly with the pestle after each application, care being taken not to add a fresh portion of oil until the last has been thoroughly emulsified. When the liquid becomes too thick to be easily stirred, a fluidrachm of water should be mixed with it, and the gradual additions of oil continued until the whole quantity has been used. The larger quantity of water may be added rapidly, without risk, after the nucleus is once properly formed.

2. **The Continental Method**—This has the great merit of never failing to produce a good emulsion if the proper proportions are used to form the nucleus, and if the directions are strictly followed. The most satisfactory proportions for cod liver oil and for castor oil may be easily remembered. Half as much water is taken as of oil, and half as much gum as of water; or it may be expressed as oil, 4; water, 2; gum, 1. The four parts of oil must be placed in a dry mortar or emulsifier and one part of finely powdered acacia added to it, stirring with the pestle; when a uniform mixture is made, two parts of water are added, not gradually, but all at once, when, upon stirring, the emulsion is quickly made. An additional quantity of water may be added to this nucleus without risk. The explanation of making an emulsion by this method is, that the particles of gum, being insoluble in the oil and surrounded by it, are prevented from separating and dissolving in the water so as to form lumps; by stirring the mixture actively the water *gradually* dissolves the gum, the oil becomes incorporated at the same time, and a homogeneous mixture is produced, the quantities of oil, gum, and water being in exactly the right proportions to form an emulsion.

A combination of the Continental and English methods has certain advantages for cod liver oil. If the Continental method is used for about half of the oil, the remainder of the oil may be added to the nucleus formed, following the English method of emulsifying. This plan requires only half as much acacia as would be needed if the Continental method alone was followed and the resulting emulsion is a purer white, more fluid, and more readily poured than when made throughout by the Continental method.

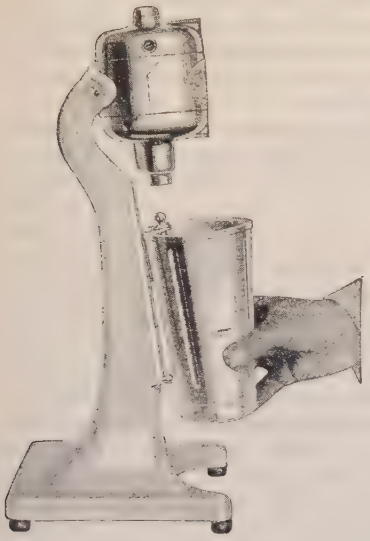
Some other oils require different proportions, for instance—oil of turpentine emulsion requires the following proportion: oil, 3; water, 2; acacia, 1. Liquid petrolatum emulsion may be made by the Continental method if the following proportion is taken: oil, 2; water, 2; acacia, 1.

It is important, when following the Continental method, to avoid all water or dampness in the mortar, bottle, or machine in preparing the oil and gum mixture. The fine powdering of the acacia is also essential for success and a thorough beating of the nucleus, when it first forms, adds to the whiteness and the perfection of the emulsion.

Emulsifiers—The small, soda fountain drink mixer, shown in Fig. 591, made by the Arnold Electric Company, is admirably adapted to the preparation of small quantities of emulsions at the prescription counter. In making large quantities of emulsions some mechanical device must be used to facilitate the rapid stirring and agitation necessary to form the nucleus. Fig. 592 represents an emulsion apparatus or egg beater made by the Whitall Tatum Company. The principle of action is so well shown here that a description is unnecessary.

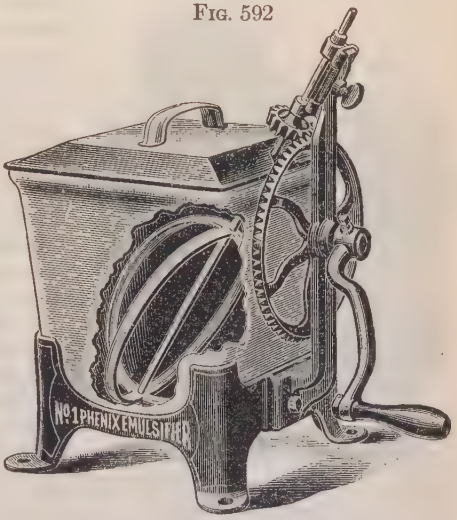
Fig. 593 shows the Clipper emulsifier made by the J. H. Day Company of Cincinnati. The tank is mounted on a strong frame, and can be easily tilted to remove the emulsion when finished; the agitators are shown in the fore-

Fig. 591



Drink mixer for emulsions

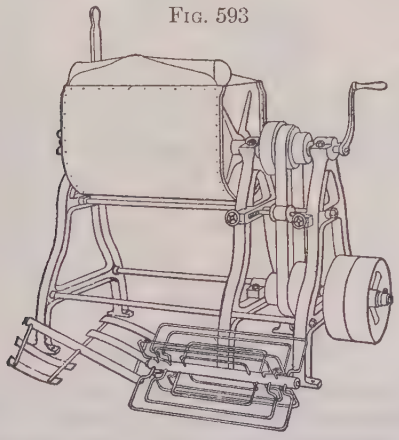
Fig. 592



Emulsifier

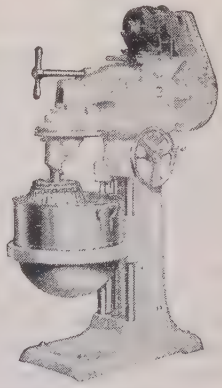
ground. With this machine a large quantity of emulsion can be made quickly. Similar machines are made by all manufacturers of pharmaceutical machinery and other machines offered for use in hotel kitchens such as that illustrated in

Fig. 593



Clipper emulsifier

Fig. 594



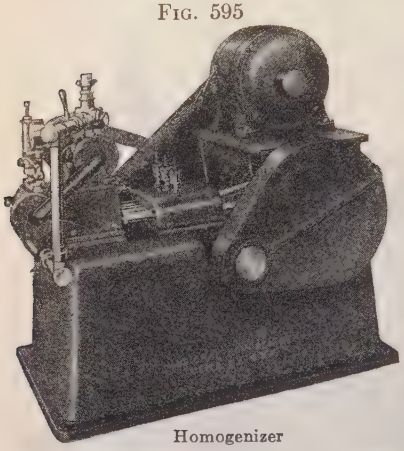
Mixing machine

Fig. 594 which is made by the Reed Machine Company are well suited to the making of emulsions, creams, tooth pastes and other mixtures.

The *homogenizer* or *viscolizer* is coming into frequent use by manufacturers in preparing stable pharmaceutical emulsions on the large scale, which it does to a degree with which the pharmacist, working with ordinary emulsifying

apparatus, can never hope to compete (see Figs. 595 and 596). In these machines the materials to be mixed or emulsified are forced under extremely high pressure between a revolving head and a fixed outer chamber. There is therefore both a direct impinging force and a rolling and grinding effect, in combination with high pressure, with the result that the particles of the mixture are broken into microscopic globules which remain in suspension almost indefinitely, forming a perfect emulsion.

FIG. 595

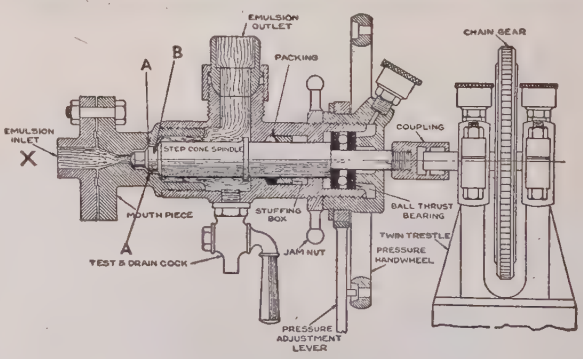


Homogenizer

Casein Emulsions—The use of casein as an emulsifier was developed by Léger, a Parisian pharmacist. He recommends a *saccharated casein*, which is used for emulsifying in a manner similar to powdered acacia. It is claimed that casein emulsions are more readily retained by the stomach, and that greater stability and perfection are secured through its use.

Saccharated casein is prepared by heating one gallon of cow's milk to 104° F., adding two fluidounces of ammonia water, allowing the whole to stand a day, and separating the lower milky liquid from the oily liquid on top. The milky liquid (*lactoserum*) is treated with acetic acid until the casein is precipitated. After washing the precipitate thoroughly with water at 104° F. it is collected on a muslin strainer and pressed; a weighed portion of the casein is dried and the percentage of moisture ascertained; the damp casein is then triturated with three and a half ounces of powdered sugar and eight parts of sodium bicarbonate for every one hundred parts of dry casein.

FIG. 596



Cross section of homogenizer

Prolonged trituration and the addition of more powdered sugar, until it amounts to nine parts in one hundred, result in the formation of a paste, which must now be dried by a gentle heat not above 86° to 90° F. After complete drying, it is powdered and sifted. To make a casein emulsion of a fixed oil, fifteen parts of the oil are gradually incorporated with a mucilage previously made with fifteen parts of saccharated casein and five parts of water. When a perfect emulsion is formed the other ingredients are added. Powdered casein is a commercial product today and is used for emulsifying oils.

Emulsifying Powders—A typical combination known as *emulsifying powder* is made by thoroughly mixing equal parts of finely powdered tragacanth, sugar, acacia and starch. Another combination consists of ten parts of tragacanth, with five parts each of acacia and gluten. About 4 Gm. of the powder should be used for each 30 cc. of oil, using the English method.

Condensed Milk—This substance has also been used as an emulsifying agent, the English method being followed. It does not, however, produce a stable emulsion.

Powdered Milk is a useful and efficient emulsifying agent being used like acacia but following the English method of emulsification. The emulsions, however, are not stable.

Chondrus Emulsions—Since acacia is subject to fluctuations in price and is often expensive, various substitutes have appeared which have been tried as emulsifying agents, one of the most successful being the gelatinous substance obtained from Irish moss. (See page 286.)

Tragacanth Emulsions—Small amounts of tragacanth, added to acacia or to gelatin solution (0.2 per cent) form excellent emulsions which do not quickly stratify.

Quillaja Emulsions—*Quillaja*, or *quillaya bark* (see page 1078), contains the principal saponin, a glucoside which is capable of emulsifying oils. This property, causing frothing in aqueous solutions, suggested the use of quillaja as an emulsifier. It has not come into extensive use, and care is necessary in employing it, as it is not without medicinal and irritating properties.

In applying the principle of emulsification to technical uses other emulsifying agents are employed, such as soap, gelatin, etc.

Preservation of Emulsions—While the official emulsions are supposed to be extemporaneous preparations, it is often necessary to make stock preparations in which decomposition will not occur. For this purpose the flavoring oils are often helpful, especially methyl salicylate, but it is usually desirable to add a preservative like sodium benzoate, one-tenth of one per cent or from 7 to 10 per cent of alcohol. The latter not only preserves the emulsion but helps to maintain a fluid consistence. As alcohol has a tendency to precipitate acacia or gum and therefore break the emulsion it should be added last and in small portions, shaking the emulsion after each addition.

Compound Emulsions—As a general rule, the addition of any alcoholic tinctures or other alcoholic preparations to emulsions destroys their homogeneity. When it is necessary to add them in compounding prescriptions, they should be diluted, if possible, with a portion of the water, and added after the emulsion is nearly finished. Alkaline solutions generally aid emulsification, by forming soaps with the resinous or oily liquids; volatile oils make better emulsions if they are first mixed with an equal volume of fixed oil.

CHAPTER C

THE DISPENSING OF LIQUIDS

EVERY convenience should be adopted to facilitate quick and accurate dispensing. The sink should be close to the prescription counter. A good draining surface for graduates to rest upon is made by fastening sheets of corrugated rubber (a piece of rubber matting) to the slightly inclined shelves above the sink. Fig. 461 shows an unusual arrangement of a sink and graduate rack, in the prescription department of Frank E. Morgan's pharmacy in Philadelphia.

In the Hynson, Westcott and Dunning prescription department, in their Baltimore store, an ideal plan has been adopted

FIG. 597

Lenox bottle brush

FIG. 598

"Practical" prescription bottle

FIG. 599

Diamond I prescription bottle

FIG. 600

Various sizes of Diamond I prescription bottles

whereby each dispenser is furnished with an ample supply of clean and dry graduates, mortars, spatulas, etc. When these are soiled they are placed on a shelf below the prescription counter until collected by a porter, who carries them to the rear of the store where there are special facilities for washing and drying apparatus. The clean apparatus is then redistributed for the use of the prescription clerks. This plan is adaptable only to the larger stores. A brush for quickly cleaning graduates should be accessible. The Lenox bottle brush, made by the Whitall Tatum Company (see Fig. 597), is a serviceable and generally applicable brush for this purpose. Needless to say that soap, a scour-

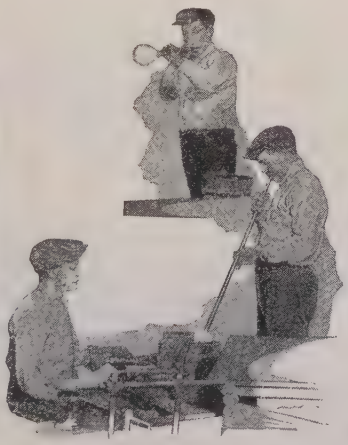
ing powder, lye solution and an acid, such as commercial hydrochloric acid, should be on hand when needed for cleaning bottles or mortars.

Bottles—The size and shape of the bottles used in dispensing liquids are largely matters of individual taste. Since the machine made bottle has almost entirely replaced the hand blown bottle in this country, the oval bottle has practically become the standard for the ordinary prescription as they afford proportionately more space for the label than either round or square bottles. Fig. 598 illustrates the machine made, "Practical" prescription bottle of Whitall Tatum Company and Figs. 599 and 600 show the "Diamond I" machine made prescription bottles of the Illinois Glass Company. Fig. 600 shows the variety of sizes made by machines, from a half-ounce to a quart, now being available. Fig. 601 illustrates a type of prescription bottle, fitted with a screw top, which are made by the Illinois Glass Company and are available in all sizes. The Owens Bottle Company are also large producers of machine-made prescription bottles.

FIG. 601

Screw cap prescription bottle

FIG. 602



The old method of blowing bottles

One of the notable improvements in the supply of prescription bottles, adopted by all of the large manufacturers, is the packing of bottles, which have been thoroughly washed and dried, in paste-

FIG. 603

The old method for finishing the necks of bottles, using a hand tool

board cartons. This avoids the great annoyance, so often experienced in former days, when the straw in which the bottles were packed, refused to leave the bottle during washing.

Figs. 602 and 603 illustrate the method whereby all glass bottles were blown until within a few years, when the bottle-blowing machine was perfected.

The glass mixture was melted in a furnace and when of proper consistence the glass blower picked up a mass of molten glass on the end of a long iron pipe, known as a blow pipe.

The amount of glass collected was determined only by the judgment and experience of the operator. The molten mass was manipulated by the bottle blower, alternately forcing air into it, through the pipe, and rolling it on a slab, until the globe of soft glass was ready to drop into the mold. This was then quickly closed, strong air pressure applied to force the glass into all parts of the mold, and, after withdrawal from the mold, broken free from the blow pipe. The neck was still to be finished, calling for reheating and shaping as shown in Fig. 603.

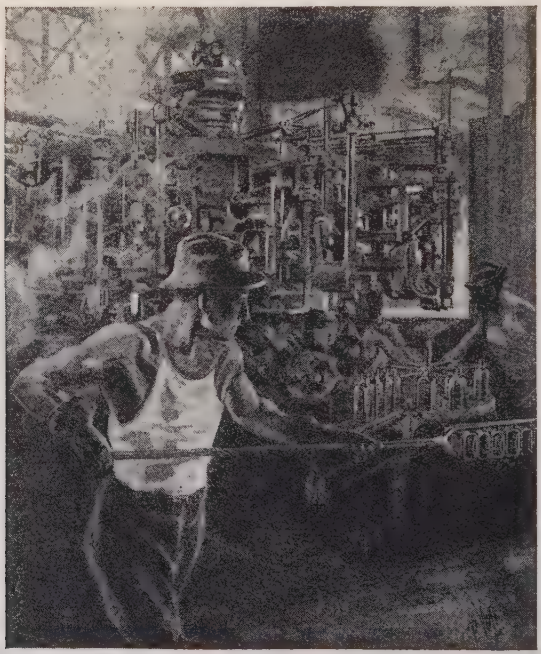
In the modern bottle-blowing machines the operation is entirely automatic

and much greater uniformity in weight of glass is secured which is reflected directly in accuracy of capacity. Furthermore, bottles are blown by this method at a great saving in cost.

This development in the bottle-blowing industry has been responsible for a tendency to adopt standard shapes for much glassware and it also lessens the use of bottles with the name of an individual pharmacist blown in the back, since the initial cost of the many molds needed by each machine is so great that the multiplying of styles becomes prohibitive.

In one machine a "vacuum" system (see Fig. 604) is employed to suck the glass into the blank mold. In the other (see Fig. 605), "gobs" of glass slide by gravity down a trough system, from a feeder attached to the furnace, into the

FIG. 604



The "vacuum" type bottle-blowing machine

blank molds of the machines below. In the first instance, the machine is taken to the glass; in the second, the glass is taken to the machine. Both "vacuum" and "gob" feed machines rotate while operating—the first continuously and the second intermittently.

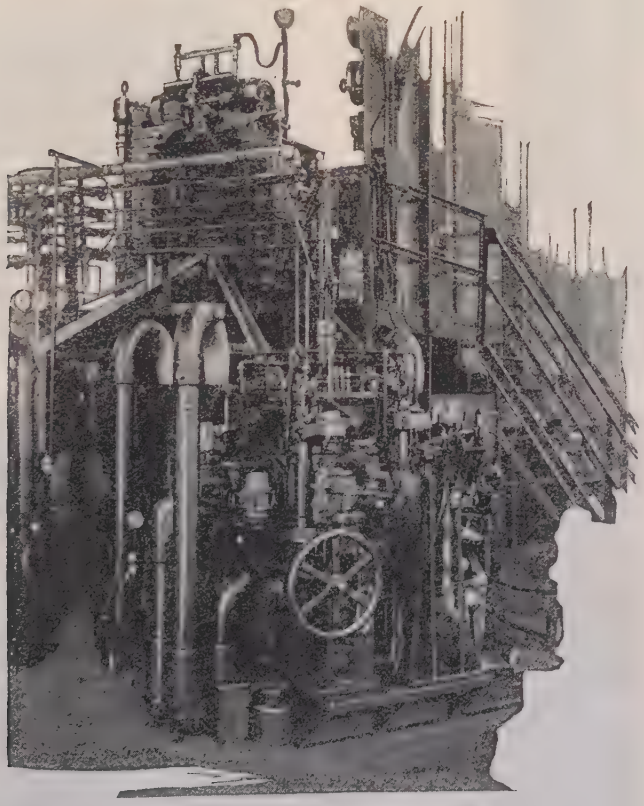
In the "vacuum" type of machine, when a bottle is blown, the glass is sucked up into the measuring blank, a metal tip is lowered which forms the "neck opening" or "finish". Then the blank mold gradually opens while the cylinder of glass is held firmly at the top by the neck ring device. The finishing mold slowly lifts up and closes on the white hot glass. Air is automatically admitted through the neck tip mechanism and the body of the bottle is blown.

This machine is made in various sizes—with six, ten or fifteen arms. The arms are all exactly alike, and each one is really a complete bottle-blowing machine. A ten-arm automatic when working on small ware will make a

revolution in ten seconds. In blowing gallon bottles, it turns more slowly, making a revolution in about forty seconds. In the operation of the huge carboy machine which stands twenty feet high and weighs over 240,000 pounds, a minute is required for each revolution.

Prescription bottles are now frequently made of amber glass, to protect the contents from the effects of the actinic rays of light. For poisonous liquids, or for liquids intended for external application, blue bottles studded at regular intervals with pyramidal points are used. These are designed to attract attention through their peculiar color and shape, and thus prevent

FIG. 605



The "gob" feed bottle-blowing machine

errors; the points render them easily distinguishable from ordinary bottles by the sense of touch, so that the patient can recognize a poisonous liquid in the dark. Fig. 606 shows the label side of this bottle.

For liquids to be administered in drop doses, bottles are provided with the stopper elongated into a dropper or, for solutions intended for the treatment of the eye, many pharmacists dispense a small, glass-stoppered bottle, fitted into a special pasteboard box having a compartment at the side in which an eye-dropper is placed.

For some prescriptions it is desirable to use glass-stoppered bottles and these should be available at every prescription counter.

Washing Bottles—The cleaning of bottles is generally a despised occupation. Where a large number of bottles of one kind and shape are to be washed, the machine shown in Fig. 607, known as the turntable rinser, may be used to advantage. The water is supplied automatically, and may be shut

Fig. 606

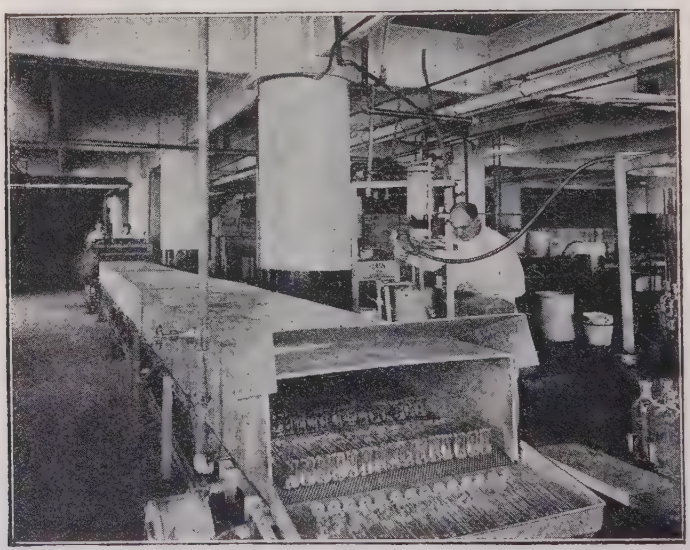
Poison bottle

Fig. 607

Turntable rinser

off by a quarter turn of the rinser; this permits continuous rinsing without undue waste of water. Much more elaborate machinery for washing and drying bottles is also available as illustrated in Fig. 608. This is marketed by the Illinois Glass Company.

Fig. 608



Bottle washing and drying machine

Bottle Fillers—Fig. 609 illustrates the "U. S. Santo" bottling outfit, made by the Illinois Glass Company. This is adapted for hand filling and on comparatively small operations. More elaborate outfits are of course available as illustrated in Figs. 610 and 611. These outfits are also sold by the Illinois

Glass Company. Fig. 612 illustrates a bottle-filling machine connected with a supply tank and filter.

Pouring Liquids—In pouring liquids from the dispensing bottles, it is

Fig. 609

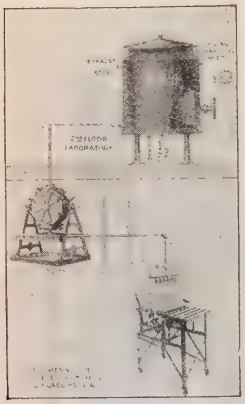
well to establish the habit of extracting the stopper with the left hand, holding it with the little finger. The graduate is held between the forefinger and thumb

Fig. 611

Bottle-filling machine

of the left hand, or, more securely, by allowing it to rest on the middle finger of the left hand, the forefinger and thumb grasping the graduate above the base, while the bottle is held in the right hand with the label uppermost and the liquid poured down the side of the graduate to avoid splashing (see Fig. 36).

FIG. 612



Supply filter, and bottle filler

FIG. 613

FIG. 614

Graduate (chipped and broken base)

FIG. 615

Dropping from shop bottle

Graduates are also used having a hard rubber base (see Fig. 613) as the base of an ordinary graduate is apt to be chipped or broken by accident (see Fig. 614). (See also graduates pages 52 and 53.)

Dropping Liquids—Fig. 615 shows the method of dropping liquids from

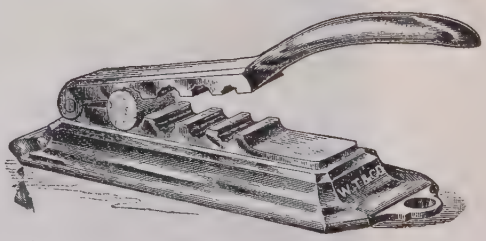
FIG. 617

Bottle with dropper

FIG. 616

Dropping bottle

FIG. 618



Cork press

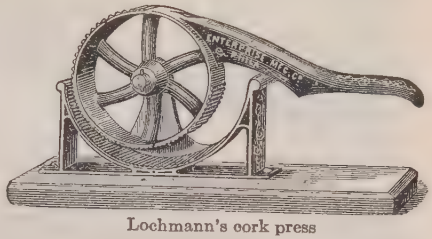
a dispensing bottle. The stopper is loosened, prevented from dropping out by holding it with the finger, and the bottle inclined so that the rate of dropping may be controlled. Fig. 616 shows a very convenient bottle for dispensing liquids which are to be administered by drops. The glass stopper has a deep conical depression extending nearly half way up the side, while the neck of the bottle is furnished with an aperture having a slightly projecting lip. When the stopper is turned so that the upper part of the depression is opposite the

little aperture in the side, the liquid may be dropped very uniformly. A corresponding depression on the opposite side of the stopper communicates with a little channel running down from the lip upon the opposite side of the bottle, so that air is supplied during the dropping. By turning the stopper half way around, both apertures in the neck of the bottle are closed. Bottles in which the stopper and a "dropper" are combined, are commonly used for eye waters (see Fig. 617). Frequently the eye lotion prescription will be dispensed

Fig. 619

French cork press

Fig. 620



Lochmann's cork press

with the bottle of solution on one side of a pasteboard box and a dropper in a separate apartment by its side.

Corks are indispensable for stoppering bottles. They should be selected with great care. There is a wide difference in price between the best quality and the common grades, but it is true economy to use only the best. Short corks, which, when inserted tightly, so as to secure the contents from leakage, do not project above the lip sufficiently to furnish a good grasp for the fingers when extracting them, should never be used for prescription bottles. Brittle, hard, or dry corks, which break off when the attempt is made to remove them, are an especial annoyance. To avoid this, corks should not be kept in a warm,

Fig. 621

Patent bottle cap

Fig. 622

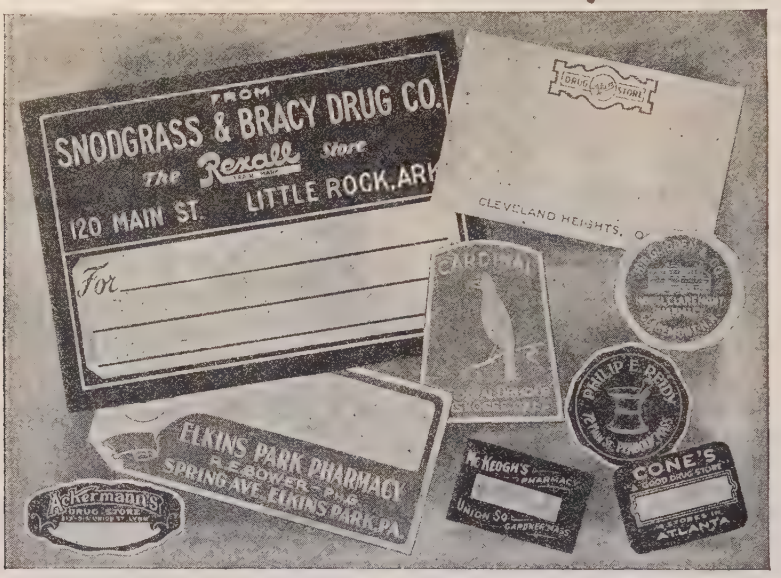
Bottle cap open

dry place, but if very dry, they should be moistened by dipping them in water for an instant, and then they should be well pressed. "Taper" corks are now invariably preferred to the "straight" form.

Pressing Corks—Fig. 618 shows a modern form of cork press which is largely used. The motion by which the pressure is effected is direct and simple. Pharmacists who incline to the grotesque in their tastes may prefer the kind shown in Fig. 619, but the practical dispenser will generally choose Lochmann's cork press (see Fig. 620), because the process of pressing the cork is more effectual, and there is less likelihood of breaking it or cracking the surface in this press than in any other, for the cork is revolved while the pressure is gradually increased. The press consists of a cast iron base, the upper portion of which is hemispherical, with the upper surface slightly corrugated; a corru-

gated cast iron wheel is placed upon an axle slightly out of the center of the curve of the base, so as to afford a gradually diminishing space between the curved surfaces. The wheel has a handle, which is raised when the tapered

Fig. 623



Typical seals and delivery taps

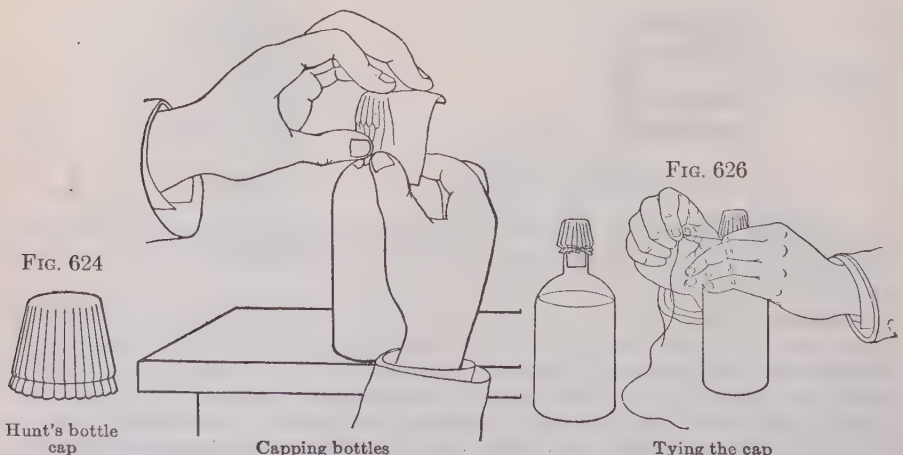
end of the cork is inserted between the surfaces; the handle is lowered, and the cork revolves while being pressed.

Many other stoppering devices have been offered, for economy or convenience. Figs. 427 and 428 show the special stoppers used for "citrate"

Fig. 625

Fig. 626

Fig. 624



Hunt's bottle cap

Capping bottles

Tying the cap

bottles, and Fig. 601 illustrates a very efficient stoppering cap which is screwed in place, and used for many stock preparations and to some extent for prescription filling.

Figs. 621 and 622 illustrate a stopper which is extensively employed in closing bottles of liquids, marketed by large pharmaceutical manufacturers, for such preparations as cough syrups, emulsions, etc.

Gummed Cork Tops—A finish may be given to corks by the use of "gummed cork tops". These are circular in form, made of paper, and the name of the pharmacist, or his monogram, is generally printed upon them in colors (see Fig. 623). These tops have largely supplanted the sealing wax finish so much used a few years ago.

Capping Bottles—The practice of capping prescription bottles with paper, kid, baudruche, or other material is most commendable, principally because of the feeling of security it gives to the patient that the contents of the bottle have not been tampered with after being dispensed. Hunt's bottle caps (see Fig. 624) are largely employed. These consist of fluted caps of colored paper, of various sizes, which are used by adjusting the proper sized cap to the corked bottle and tying it on. An equally neat effect may be secured, with a little practice, by capping a bottle with a piece of fancy paper, as shown in Figs. 625 and 626. The paper which must be of light weight and tough, as "parchment" or "bond" quality, is held in the center upon the cork by the forefinger of the left hand, while the flutes are made by "plaiting" them in with the forefinger and thumb of the right hand. It is then secured by tying with twine, a bow with short ends being preferred, because it is less likely to be interfered with by a messenger, on account of the difficulty of retying it.

If the string is tied in a knot it usually remains around the neck of the bottle after the cap is torn off and accumulates the medicine, especially if that is syrupy, producing an unsightly appearance. Sometimes the twine is tied in a knot with long ends and these are carried over the top of the cap and held in place with wax or a paper seal. A double loop of the string is frequently applied to a cap in such a manner that if either end is pulled it will untie. After tying, the "excess" of paper is trimmed off by using scissors with sharp points or the excess of paper may be turned up and trimmed off in such a manner that a ruffled effect is produced. Another method which is frequently employed for trimming the paper close to the string, is through the use of a sharp pocket knife. By pressing the cutting edges of the blade on the paper cap, against the neck of the bottle, the excess is quickly and neatly cut away.

CHAPTER CI

EXTEMPORANEOUS POWDERS

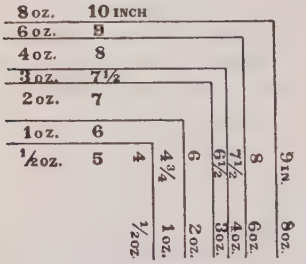
Pulveres—*Powders*

Powders—The official compound powders have been considered in Part III, page 478. In this chapter it is the intention to discuss powders which are prepared extemporaneously. This form of administration often furnishes a convenient means of supplying dosage forms of medicines which are not excessively bitter, nauseous, or otherwise offensive to the taste. Powders are not a proper dosage form for substances which are corrosive or deliquescent. Medicines which are to be given in large doses are not ordinarily administered in this form but there are exceptions and a very common prescription today is illustrated on page 1813 (No. 32111). Powders constitute one of the oldest dosage forms but are being largely replaced by capsules or tablets. It offers, however, distinct advantages in the administration of some drugs since their preparation permits the reduction of the material to a very fine state of subdivision, a physical condition which frequently intensifies the therapeutic activity. This is illustrated in the section on "Homeopathic Pharmacy", Part XII, and is a well-known factor in the efficiency of calomel and sodium bicarbonate mixtures and in Dover's powder.

DISPENSING OF POWDERS AND SOLIDS

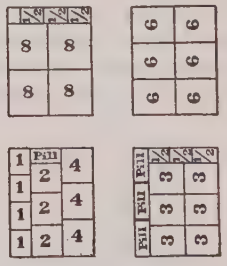
Many of the manipulations required in dispensing powders and solids, such as weighing, measuring, labeling, etc., have been described in previous

FIG. 627



Gauge for cutting paper

FIG. 628



Gauge for cutting paper

chapters; therefore only those operations which are peculiar to them, or which have not been considered, will be treated in this chapter.

Folding Packages—This is one of the first operations taught to the tyro. White paper, of good quality, should be used. It is most economical to buy the paper in quantity (several reams) and have it cut by the dealer into such sizes as the demands of the business require. Jacoby's gauge is useful in this connection; it is illustrated by Figs. 627 and 628. Fig. 627 represents the sizes of paper which are suitable for wrapping packages of the size indicated. In Fig. 628 the numbers indicate the method of *cutting a sheet of paper without waste.*

The cutting of large sheets of paper into wrapping sizes has largely been

abandoned although some pharmacists still retain cut paper at a convenient place near the prescription counter so that packages may be finished in the department. It is desirable to have large sheets of paper of good quality somewhere within reach of the wrapping counter, since large packages must sometimes be wrapped.

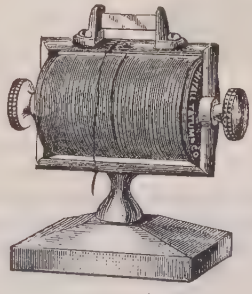
Rolls of Paper—The almost universal custom today is for wrapping paper to be kept on rolls. These are mounted on frames having a weighted knife, by which a piece of paper of the desired size can be easily and quickly torn off.

The selection of this paper is important since its quality and appearance will have much to do with the general impression made by the package leaving the drug store. A majority of pharmacists today still use what is called "white drug paper". Many other varieties are offered, frequently in assorted colors and often mottled. It is recommended, however, that the average pharmacist should continue to use pure white paper with red or blue twine. Occasionally, a firm will adopt an individual shade of paper and employ this exclusively, making that individual store distinctive. This as an advertising

Fig. 629

Paper package

Fig. 630



Twine reel

Fig. 631

Twine holder

policy may be justified if the color adopted is not objectionable, causing offense to those who carry the package.

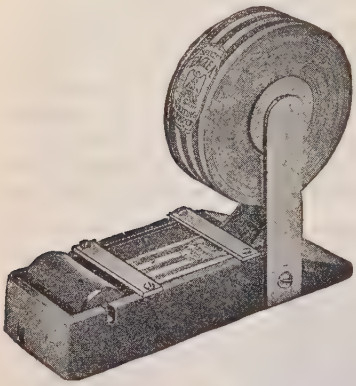
In folding a package, the proper size of paper is selected and laid upon a flat surface, the substance is deposited in the center, and the edge nearest the operator is laid against the opposite edge, and a fold made with the thumb and forefinger. The width of the package will depend upon the width of this fold. The end of the partly formed package on the left hand is now temporarily tucked in, so that the contents shall not fall out, and the package is lifted into an upright position, with the fold toward the operator; the open upper end is then neatly creased and folded into a wedge-shaped flap. The package is now reversed, and the first partly formed tuck is loosened and folded into a flap of the same size and shape as the one just made at the other end. The edges of the package are squared and gently pinched into shape, the label is pasted on so that the edge coincides with the edge of the fold, and the package is tied, as shown in Fig. 629. Packages of many of the largely sold household remedies, such as Epsom salt, compound licorice powder, etc., were prepared beforehand in this manner in the old-time pharmacy that they might be available for counter sales. It is almost the universal custom today, however, in preparing such drugs and chemicals for popular sale to enclose them in pasteboard cartons. This is of great convenience to the customer since they can be readily opened and closed and will frequently occupy a place in the medicine

closet. The old-fashioned drug store package when once opened was difficult to close and proved to be an unsatisfactory permanent container.

Twine—Fig. 630 shows a very convenient twine reel. A glass twine holder, made by the Whitall Tatum Company, is shown in Fig. 631.

The twine used in a drug store package should be of good quality and for small packages must be of light weight. A waxed, linen twine obtainable in a variety of colors, preferably dark blue or red, is sold under the name of "druggists twine". Spools (illustrated in Fig. 630) usually weigh about 4 ounces. Other twine is available but the characteristics described should be maintained. The soft "Sea Island twine", commonly used in other stores is not so desirable, at least for the wrapping of prescriptions, if appearance is to be a factor. Fig. 632 shows a roll of gummed paper, in strips, which is moistened by a wet pad as the paper is pulled off. This often replaces twine for the fastening of wrapping paper, especially for heavy packages. It is made by The Liberty Paper Company of New York.

Fig. 632



Gummed paper roll

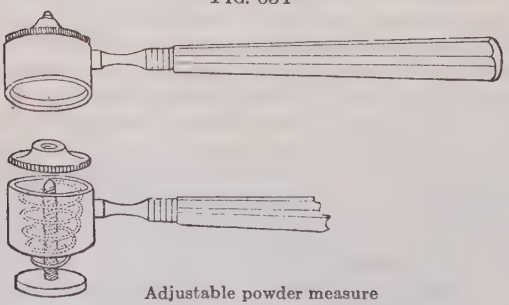
Fig. 633

Seidlitz powder measure

Measuring Powders—Where large quantities of powders having a uniform weight are needed, the powder measure shown in Fig. 633 may be used. This is made of hard wood, and consists of two ovoid cups of different sizes, joined like an egg cup. This measure is used in preparing seidlitz powders, the larger sized cup holding the requisite quantity for the alkaline mixture, the smaller cup being intended for the acid.

The measure should never be used without carefully testing its accuracy beforehand. This is done by heaping the powder upon a piece of glazed paper

Fig. 634



Adjustable powder measure

Fig. 635

Prescription sieve

and pressing the cup downward through the powder until its edge rests uniformly upon the paper. The edge of the cup is then placed upon the powder paper and slightly tapped, when the contents readily drop out. The weight should be noted, and the operation repeated several times, until the average weight is correctly determined. It will soon be possible, to regulate the pres-

sure and height of the powder that the variation from the proper weight will practically be negligible. This method should not be employed where great accuracy is necessary, and the measure should be repeatedly tested. Fig. 634 illustrates an adjustable measure for powders offered by Limousin, of Paris.

Fig. 635 shows a useful little covered sieve which may be found convenient for sifting small quantities of powders when required in compounding prescriptions. It is nickel plated and made in three parts.

Dividing and Folding Powders—The preparing of individual powders, sometimes known as *chartulæ*, at the prescription counter is a frequent one, and the practice of accurately dividing powders is one which must be quickly acquired. The best method of attaining proficiency in this respect is to weigh out a definite quantity of a powder (120 grains), and, after dividing it, with the use only of a spatula (see Figs. 636 and 637), into twelve portions, as nearly equal in quantity as can be judged by the eye, to then weigh each portion separately and note the weight, so that any deviation from the proper weight (10 grains) will be discovered. Through practice it will soon be realized that very accurate division may be secured. All the powder papers should be creased at once, by folding down a margin on the top, so that they shall be uniform. They should be placed regularly and as close to one another as is convenient. In Fig. 639 the usual arrangement is shown. Where the operator has not sufficient practice to trust to his judgment of the quantity for each powder, the whole quantity may be collected upon a smooth card, flattened into a rectangular shape, and divided with a spatula into the exact number

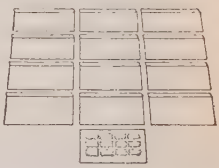
Fig. 636

Powder spatula

Fig. 637

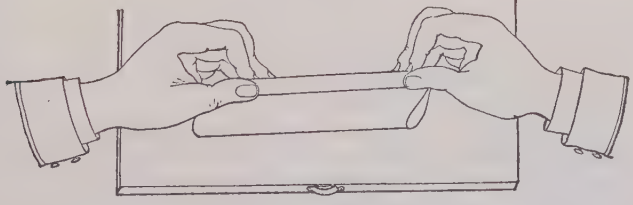
Powder spatula

Fig. 638



Arrangement for powder papers

Fig. 639



Folding the powder

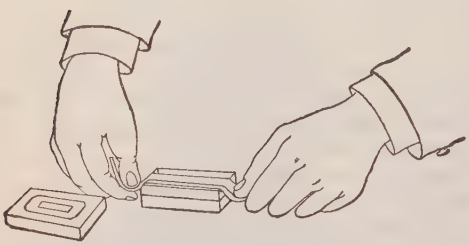
of equal portions required for the number of powder papers. Each portion may then be transferred to its appropriate paper from the card by the spatula. Some pharmacists insist upon the weighing of each powder to insure accuracy.

The operation of folding the powder is illustrated in Figs. 639, 640 and 641. The uncreased edge of the paper is brought over so that it lies exactly in the crease, and the fold turned down and folded over toward the operator, the depth of the fold determining the width of the powder.

When a number of powders are called for, it is best to dispense them in a shallow powder box (see Fig. 640). It is customary to use the sides of the box as a gauge. In the hands of an experienced operator neat results are easily obtained in this way, although the use of the powder folders shown in Figs. 642

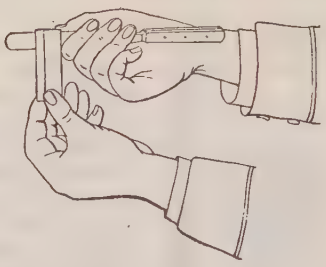
and 643 give a more uniform edge to the powders. A cheap gauge may be made by tacking a piece of tinned iron underneath a convenient shelf, so that a portion having a width slightly less than that of the powder box will project. A very true edge may be made by folding the powder over a spatula, as shown in Fig. 641. The custom so largely followed of flattening the folded powder with a spatula is objectionable since it has a tendency to pack the medicine and render it more difficult to mix with water for administration. The paper

Fig. 640



Making the end creases

Fig. 641



Creasing with a spatula

used for folding powders should be thin, glazed cap paper, and for deliquescent substances, parchment, waxed, or paraffined paper should be employed.

When paraffined powder papers are used they may be folded inside of the regular powder paper, with one operation. A very attractive addition to the powder paper is to have the name of the pharmacist printed on the unfolded paper in such a position that when folded it will appear uniformly on the edge of all powders. Powder papers, so printed, can be more readily folded with even ends than plain paper, since the printed edge serves as a guide in folding.

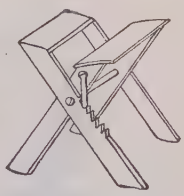
Another suggestion to add to the attractiveness of folded powders, is that proposed by John S. Trinsey, who dispenses powders which are held in place by a small strip of paper, pasted to the shoulders of the powder box. This narrow strip of paper, preferably carrying the name of the firm, acts as a seal to the powders, the protection to the customer being similar to that provided by a bottle cap when used on liquid prescriptions.

Fig. 642

Powder folder

There have been a number of devices offered during the last twenty-five years for the dividing of powders at the prescription counter, such as the "Michaels" powder divider, the "Diamond" powder divider, and the "Weill" powder divider, but these are no longer available commercially which is the best evidence that the pharmacist finds the actual weighing of each powder or the division by some other mechanical means, without the use of apparatus, entirely satisfactory. These older forms of apparatus were described and illustrated in Remington's "Practice of Pharmacy", 6th edition.

Fig. 643



Powder folder

Powder Boxes—A large variety of powder boxes are offered by various box manufacturers. On the older box the label was always pasted on the top but in many of the newer boxes, the name of the pharmacist is lithographed or embossed attractively upon the top of the box and the lid is hinged to avoid the mixing of lids when several boxes are in the same home. The label is

pasted inside the lid. This same principle applies to pill boxes. The shouldered box is still extensively used. Various pill and powder boxes, made by the Dennison Manufacturing Company, are illustrated in Figs. 644 and 645 and there are many other manufacturers.

FIG. 644

Pill and powder boxes with hinged lids

FIG. 645

Pill and powder boxes with slip lids

Cheaper slide boxes are also employed by some druggists but they are not well adapted for prescription use because of their lack of strength and unsatisfactory appearance.

CHAPTER CII

CAPSULES AND CACHETS

Gelatin Capsules

The capsulating of medicinal substances, both dry and liquid, in gelatin shells is one of the most largely used methods for the administering of medicines today. The gelatin capsule was invented by A. Mothes, a French pharmacist, in 1833.

Three distinct forms of capsules are used. One form is known as "*hard capsules*" and consists of two sections, one slipping over the other, completely surrounding the medicine. Their shape is illustrated in Fig. 646. These capsules are filled by either massing the material and rolling it into elongated pills for insertion into the capsules or by introducing the powdered material into the larger end of the capsule and subsequently slipping on the cap.

Another variety is known as "*soft capsules*". These consist of a soft globular shell of gelatin, containing sufficient glycerin to retain permanent flexibility. When manufactured for use by the prescription pharmacist and as obtained commercially, these shells are hermetically sealed to prevent the walls from collapsing. The end where they are to be opened for filling is also elongated so that when this is cut off sufficient gelatin is provided for the sealing. Soft elastic capsules are intended primarily for the administration of oily liquids.

A third form of gelatin capsules is known as "*pearls*". These are also used for oily liquids, although occasionally solid constituents are inserted into each pearl with the oil. Pearls are made only by the pharmaceutical manufacturer who must install special machinery. Their manufacture is described on page 1682.

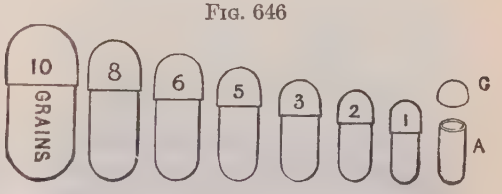
Capsules of all kinds are supplied in a variety of sizes. The hard, empty capsules (see Fig. 646) are numbered from 00, the largest size usually employed in prescription filling, to No. 5, which is the smallest, although special sizes are also obtainable. In Fig. 646 the approximate capacity in grains of these capsules is indicated although this will vary because of the density and weight or, in some other instances, the bulk and lightness of many substances used in medicine.

It is usually necessary for the dispenser to determine the size of the capsule needed for a given prescription through a test, although the skilled dispenser, having calculated the weight of the material to compose a single capsule, will often select the correct size immediately. If the material is powdered, the test will consist of the filling of the longer end of a capsule, which is believed to be the correct size, and closing it. It is then placed upon one of the scale pans and an empty capsule and the desired weights are placed on the opposite pan. If the material in the capsule proves to be too heavy a smaller size capsule must be taken and the test repeated. If the filled capsule is light, it is possible that more can be forced into it by increasing the pressure or, if necessary, some of the material may be placed in the cap. This, however, is not desirable as it tends to decrease the accuracy of subdivision and it is much better to select another size, the large end of which will exactly hold the correct quantity. No more accurate measurement could be devised than the large end of an empty capsule, as it is accurate to at least the one one-thousandth of an inch and a fairly uniform pressure can be applied.

Hard capsules are made largely from gelatin and sugar, the Pharmacopœia permitting gelatin for this purpose to contain 0.15 per cent of sulphur dioxide to prevent decomposition during their manufacture. They are made by very complicated and expensive machinery. Manganese bronze pins, set in plates, each plate carrying from 200 to 500 pins, are dipped into the gelatin solution, which must be maintained at a uniform temperature and of an exact degree of fluidity. If the gelatin solution varies in thickness it will correspondingly decrease or increase the thickness of the capsule and this is serious since a variation of not more than one one-thousandth of an inch is sufficient to make either a loose or a tight joint. When the pins have been withdrawn from the gelatin solution, a current of dry air is blown over them to make the gelatin "set". Then each capsule is trimmed to give it uniform length and they are thoroughly dried in closets through which a strong blast of air is forced. The finished capsule is finally stripped from the pins and assembled, the entire process being mechanical.

Filling Hard Capsules—For this operation several devices are employed. In the retail drug store for prescription filling, the usual plan is to mix the ingredients by trituration, reducing all to a fine powder; place this upon paper and press it to uniform thickness. Granular powders do not readily pack in the capsule but have a tendency to drop out. Crystalline substances, especially those which consist of a mass of filament-like crystals as the quinine salts, are not easily fitted into capsules unless powdered.

FIG. 646



Hard gelatin capsules showing capacity

The mass of powder is flattened so that the stratum of powder is not greater than about one-third the length of the capsule which is being filled. This avoids the soiling of the fingers and incidentally the soiling of the capsule. The capsule having been selected so that it will hold the required weight in the larger end, as already described, the cap is removed, held in the left hand, and the larger end pressed into the powder, repeatedly, until it is filled. The cap is then slipped into place and the weight tested. Experienced prescriptionists are finding it possible to hold two, three, or even more capsules in the hand at one time, remove the caps with the other hand, fill the larger ends at one operation and replace the caps. This greatly increases the rapidity of filling. No matter how carefully the capsule has been filled it should be wiped with clean cheesecloth or shaken with clean granulated sugar to remove any bitter or disagreeable medication which may have adhered to the outside. Remington's Practice of Pharmacy, Sixth Edition, illustrates some of the older capsule fillers. Such names as Whitfield, Eastman, Davenport, and Raymond are among those who devised such apparatus.

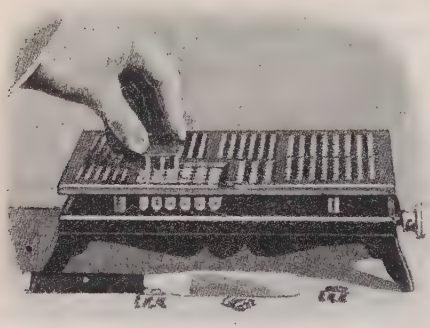
Dr. N. S. Davis, in the *J. A. M. A.*, suggests the use of a wax mass consisting of 1 part of beeswax and 3 parts of castor oil with which a number of deliquescent medicinal substances may be incorporated to advantage before inserting them in hard capsules.

He suggests the use of this in the massing of the iodides, in 10 to 12 grain doses, 1½ grains of the wax mass being used for each capsule. It is also possible to dispense guaiacol, and oil of santol, in 5 minim doses, mixed with about 1½ grains of the wax mass and even 2 or more grains of iodine, if well diluted with the mass, at least 5 grains being used for each grain of iodine.

The Ihrig capsule filler for powders is shown in Fig. 647, and consists of a stationary base with a square, polished, movable table containing perforations for holding the empty capsules; the table is raised and lowered by a thumb screw. The perforations are arranged in fields of sixty each for five sizes of capsules, and of fifty-six each for two sizes of capsules. The lower portion of the capsule should rest on the base at the beginning of the filling process, and the upper plate raised so that the top of the capsule is slightly below the surface of the upper plate. A metal bevelled square is next placed in proper position, as shown in Fig. 647, so as to exclude the perforations not in use from the capsules which are to be filled; the powder is then distributed over the capsules and pressed down by means of a metallic triple punch. When these are filled, the upper plate is lowered by turning the thumb screw, the cap adjusted, and the capsules are finished.

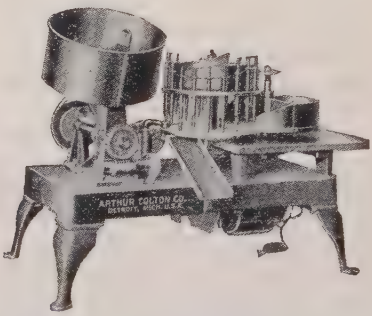
The Ihrig capsule filler is not now obtainable but has been so largely used that it was thought desirable to refer to it here. Numerous other devices have been used for capsule filling on a large scale; they are usually operated upon

Fig. 647



Ihrig capsule filler

Fig. 648



Colton capsule filler

the principles already explained. In the Colton capsule fillers one machine is semi-automatic, the operator removing and replacing the caps. Another machine of Colton (Fig. 648) automatically removes the caps, presses the larger end into the powder repeatedly, until filled, replaces the cap, and finally cleans the outside of the capsule. This machine will fill about 20,000 capsules per working day. Colton has also perfected a capsule filling machine which will fill from 70,000 to 90,000 capsules per working day. This machine is obtainable only on a royalty basis.

Fig. 649 illustrates a capsule filling machine which is now available through Sharp and Dohme of Baltimore. The capsules must be placed in the machine by hand but the upper plate carries a clamp which holds the caps and makes it possible to remove and replace them—mechanically.

The plate holding the larger capsule ends is perforated for three sizes, those most frequently used at the prescription counter, making a very useful apparatus for prescription filling.

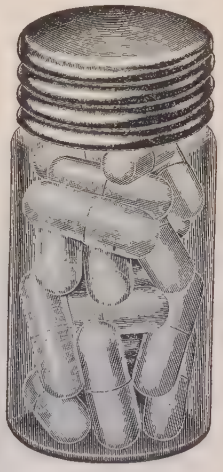
Hard capsules may also be filled with oils and this is the most frequent practice at the prescription counter when such liquids are prescribed. They are usually filled with the help of a medicine dropper, care being taken to avoid soiling the outside of the capsule. As a specific number of minims are usually specified as the content of each capsule, the first step is to determine

the equivalent number of drops. This is done by dropping the liquid from the dropper to be used, into a minim graduate, counting the drops which are equal to the corresponding minims. The cap is then removed, the number of drops of liquid introduced into the larger end, while holding it in the hand, and the cap must then be immediately replaced but in such a manner as to seal the capsule. In sealing hard capsules, which have thus been filled with liquids, the cap or larger end should be pressed upon a small mass of absorbent cotton in a pan or dish, the cotton being saturated with water of boiling temperature or with diluted alcohol. The cap, when placed upon the other end of the capsule must be given a rotary motion until it adheres. Care must be taken to avoid an excess of water or moistening it beyond about one-eighth of its length, else the cap will collapse. It should be remembered that gelatin is

Fig. 649

Sharp and Dohme capsule filler

Fig. 650



Screw cap homeopathic vial

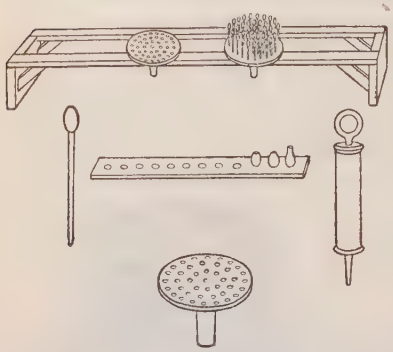
not soluble in cold water and therefore imperfect sealing results if hot water is not used.

Hard capsules are dispensed in pill boxes (see Figs. 644, 645 and 679) or in screw cap homeopathic vials, of which there are a large variety (see Fig. 650).

Soft Elastic Capsules—The soft capsule is made in much the same manner as the hard capsule only that the machines are less elaborate and much more of the work is by hand. Figs. 651 and 652 illustrate soft gelatin capsule molds of globular shape, characteristic of soft capsules, these are dipped in the gelatin solution. These molds must be slightly greased each time before they are dipped to insure the removal of the capsule from the pin. If the soft capsules are to be used immediately they need not be sealed until filled. These soft capsules, after cutting off the elongated tip, are placed in an upright position in holes in a board (see Fig. 651). They are then filled by the skilful use of a syringe, burette, or, on the small scale, with a medicine dropper. Great care must be taken that oil does not touch the edge of the capsule, since such an accident would render it impossible to seal the capsule. There is less danger of soiling the edge if the outside of the dropper or nozzle is wiped clean with absorbent cotton and then inserted entirely within the capsule before the oil is allowed to flow. If the attempt is made to drop the oil into the open-

ing of the capsule it is almost certain to touch the sealing edge and soil it. The final operation of sealing is accomplished by passing over the opening a small glass rod or brush, or preferably a loop of wire, carrying the warm glycerin-gelatin solution used for the sealing (see formula below). When using this solution it must not show a tendency to form a thread of gelatin as the sealing is attempted, otherwise the cap will be pulled off as the sealing tool is withdrawn. If too thick or sticky it can be readily restored to the proper consistence by stirring in sufficient warm water. When the capsules are sealed they are allowed to stand a few hours on the supporters to dry, and are then spread out on a sheet of white paper to detect any that may be imperfectly sealed. The properly filled capsules are then ready to be packed in boxes for the market.

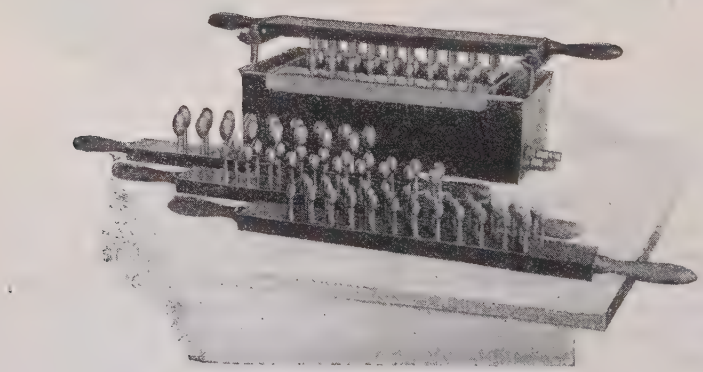
FIG. 651



Soft elastic capsule molds and filling rack

Pearls or Globules differ from hard gelatin capsules in shape, being globular, and in being usually smaller in size than soft elastic capsules. In addition, they show no air space, the gelatin shell being completely filled with the medicinal substance. Their preparation requires the use of special apparatus, and they cannot be profitably made on the small scale. The mixture of which the shell of the globule is composed consists generally of about the following formula: Gelatin, best grade, water-white, 10 pounds; acacia, 1 pound; glycerin, 1 gallon; water, 2 gallons. Heat the

FIG. 652



Soft elastic capsule molds

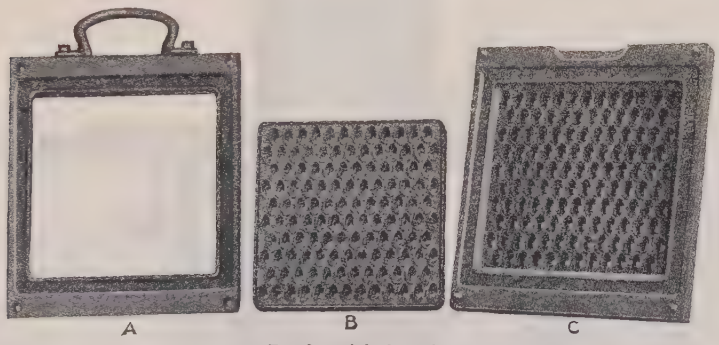
mixture on a water bath for twelve hours, maintaining the consistence by the addition of water as required, and then run onto iron plates, the surfaces of which have been amalgamated with mercury. This forms sheets of gelatin which should be about one-sixteenth of an inch in thickness.

A pair of molds which are termed upper and lower molds are needed (see Figs. 653, 654, and 655). When the lower mold is placed upon a level surface, a leaf of gelatin (see Fig. 656) should be laid over the entire face of the matrix, extending out and over the edges of the frame which has previously

been slightly heated on the warming table; the gelatin leaf thus placed will soon conform itself to the various corners and ledges found in the frame; this is now ready to receive the liquid, of which a measured quantity has been previously placed in a graduate. This should be poured upon the sheet of gelatin spread upon the lower half of the mold and when this is done, the upper gelatin leaf is placed upon the liquid surface by slightly rolling it over and across the liquid; this is done to exclude every particle of air. The upper mold is now placed over the lower, through the guidance of dowel pins, and the "flask" is now ready for compression. It is placed upon the table of a press, where it is slid into position by the medium of guiding grooves, pressure is applied, and the table rises until the sealing point is reached; the table then returns to its place of starting. The molds are now separated and the net containing the globules removed; the globules may be quickly extracted from the net, by catching it at opposite corners, and giving it a sudden stretching, repeating this at the remaining corners.

In order to make pearls or globules it is necessary to prepare the gelatin leaf or film very carefully, and of the required thickness. Fig. 656 shows

FIG. 653 FIG. 654 FIG. 655



Pearl or globule mold

Colton's leaf making machine, which consists of a jacketed copper tank in which the gelatin mixture is placed. This is supported on a grooved "warming" table, so constructed that receiving plates may slide smoothly upon it. The gelatin mixture is heated by turning on the steam to the copper tank, and the flow of the liquefied mixture upon the receiving plate is controlled by the faucet. Any excess is skimmed from the plate by an adjustable gauge, so that the thickness of the film or leaf can be fixed exactly. The film sets after cooling, and is placed in a seasoning kiln to secure the desired consistence for use in the pearl or globule mold.

Enteric Capsules—There has been considerable demand in recent years for capsules which will not dissolve in the stomach but which will deliver their medication in the intestinal tract. The substances usually dispensed in this manner are sodium and zinc phenolsulphonate, as intestinal antiseptics, sodium salicylate, sodium carbonate, potassium iodide, creosote, oil of sandalwood, etc. Such capsules are termed enteric and various plans have been suggested to accomplish this purpose. *Salol coating*, which has been used for the making of enteric pills, has also been applied to hard capsules, with a fair degree of success. The coating is applied in the manner described under pill coating (see page 1731), but greater care is necessary to secure a complete

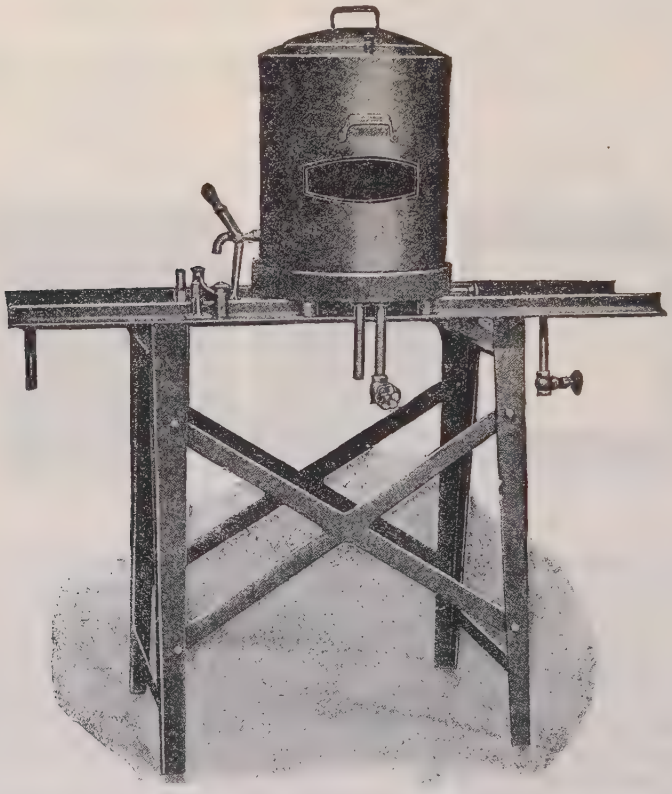
coating, especially on the ends of the capsules. The capsules being flexible and the coating very brittle, it is necessary to handle them with care to avoid cracking off the coating, and in dispensing it is best to pack them in cotton in a box or vial.

Another suggestion has been the incorporation of the medicinal substance in a mixture of solids and fats, the following type formula being suggested:

Medication	0.6 Gm.
Prepared suet	0.3 Gm.
Paraffin	0.15 Gm.

Melt the fatty substances, incorporate the finely powdered medication, and insert into capsules of proper size.

FIG. 656



Colton's pearl or globule leaf making machine

Yet another form is the so-called *glutoid capsules*. These are prepared by subjecting hard or soft capsules, containing the medication and carefully sealed, to the action of formaldehyde until they become insoluble in the stomach, but retain their solubility in the intestine. Excessive treatment will render them completely insoluble, and it has also been shown that the action of formaldehyde on gelatin is progressive, so that capsules so treated are apt to lose their solubility if kept too long. Scoville suggests their immersion for exactly thirty seconds in a one per cent solution of formaldehyde, drying and holding

for two weeks to allow the formaldehyde to act upon the gelatin, before dispensing. Such capsules have been found to remain enteric for at least a year, but if treated with stronger solutions or for a longer time they soon become insoluble. This process is adaptable for stock capsules. Capsules so treated should not dissolve within three hours when immersed in a 0.5 per cent solution of hydrochloric acid containing a little pepsin, the temperature being maintained between 37° and 38° C., but after resisting the above treatment they should dissolve within five hours when digested in a 0.5 per cent solution of monohydrated sodium carbonate, maintained at the temperature named above.

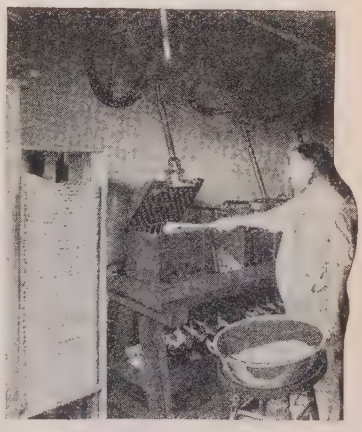
An ingenious means of proving that the capsules are enteric is to prepare a test capsule containing a small quantity of calcium sulphide and methylene blue and subject it to the same formaldehyde treatment as the other capsules. The test capsule is then swallowed and if the eructations caused by a draft of carbonated water, taken several hours later indicate by the odor or taste the liberation of sulphide in the stomach it may be considered as evidence that the capsule has not been sufficiently treated. If, on the other hand, the urine is not colored blue within a reasonable time the treatment has been too extended and the capsule has not dissolved in either the stomach or the intestine.

Cachets or Konseals

[Also known as Wafer Capsules, Chartulæ Amylaceæ, Capsulæ Amylaceæ]

The credit of bringing the *cachet*, or, as it is sometimes termed, *cachet de pain*, into use belongs to Limousin, of Paris. Wafers have been in use many years. Wafer sheet is made by pouring a mixture of flour and water upon hot greased plates, or between two hot, polished, revolving cylinders separated at a proper distance, so that the water is evaporated and a sheet of wafer produced. This is illustrated in Fig. 657.

Fig. 657



Manufacture of cachets

The properties of wafer sheet admirably fit it for administering nauseous powders. When dry, it is in non-adhesive, stiff, somewhat brittle sheets, slightly thicker than ordinary cardboard. It is tasteless, and harmless when taken into the stomach. When moistened with water, its character is entirely changed; it becomes soft, elastic, and slippery. Powders may be administered by Kollme's method, by floating a piece of wafer sheet upon water, and, when thoroughly softened, passing a tablespoon underneath and lifting it out, then depositing the powder in the center and folding over the corners so as to thoroughly enclose it. If water is then poured into the spoon, the concealed powder may be swallowed without any disagreeable taste being perceived.

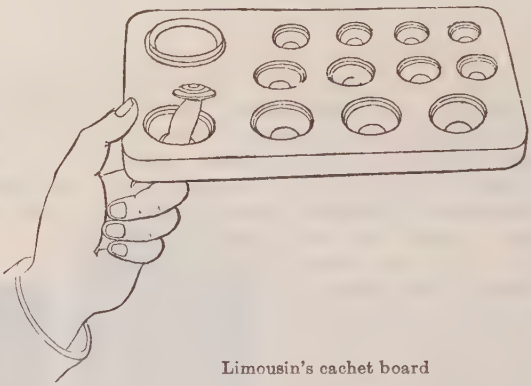
Little envelopes made of wafer sheet (Johann Schmidt's *Saccelli Amylacei*) can now be had which may be filled with bitter or nauseous powders, then sealed and moistened before swallowing; these are more convenient than the wafer sheet above described. The empty envelopes can be furnished to a patient, and he can transfer the powders from the papers which he has received from the pharmacist, and thus prepare each dose himself. The "saccelli" take up little room, and if the patient is traveling, they serve a useful purpose.

The cachet is an improvement on the above, because no more wafer sheet is used than is absolutely necessary to enclose the powder, and thus the bulk is diminished. Cachets are lenticular or spoon shaped disks of wafer sheet, of various sizes. The powder is deposited in the dry cachet, and the margin is moistened with water. An empty cachet of exactly the same size is placed

Fig. 658

Bottles for sealing cachets

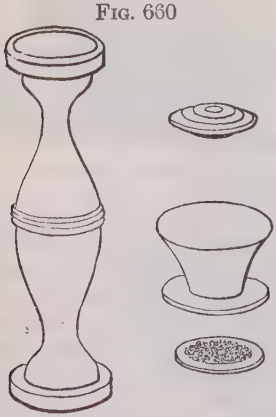
Fig. 659



Limousin's cachet board

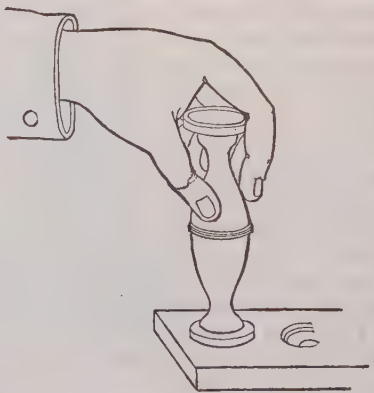
on top, with the convexity upward, and pressure is made upon the margin, with the effect of tightly sealing the cachet and enveloping the powder. Elaborate apparatus—the necessity for which, however, is not apparent—has been devised to effect the sealing of the cachets. The simplest method upon the small scale is as follows: Two bottles are provided (a one-ounce wide-mouthed

Fig. 660



Cachet wetter, cachet funnel, cachet containing powder and finished cachet

Fig. 661



Sealing the cachet

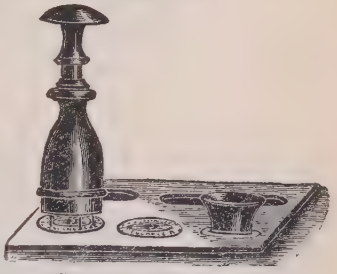
bottle for the middle sized cachet answers very well), and, one of the cachets being placed upon the lip of one bottle, the powder is carefully deposited in the center without soiling the outside edge; the margin of an empty cachet of the same size is then moistened by quickly passing it over a piece of wet felt, or it is pressed into a second bottle until held firmly and then inverted upon a piece of moistened filter paper.

It is then laid upon the cachet containing the powder and the lip of the other bottle is now applied to the cachet with sufficient pressure to seal it effectually.

The position of the bottles is shown in Fig. 658. Limousin's improved method is similar in principle, although, of course, more elaborate. A board, with depressed perforations for three sizes is shown in Fig. 659. Empty cachets are placed upon the depressions, and the powder is deposited in the center with the aid of the small powder funnel (see Fig. 660). The "wetter and presser" is shown to the left of the funnel; this is of two kinds of wood, joined in the middle—one end being hard, light colored, and highly polished, the other being dark colored and somewhat absorbent. The end of the latter is used to moisten the margin of the cachet by first placing it upon a piece of moist felt and then applying it to the cachet; an empty cachet is now laid upon the one containing the powder, and the "presser" end is applied with some force so as to seal the cachet (see Fig. 661); the sealed cachet is pushed up from below, as shown in Fig. 659.

A less expensive apparatus for filling and sealing cachets than that made by Limousin may be obtained from the German importing houses (see Fig. 662). A rectangular sheet of thick rubber cloth is perforated with twelve circular holes, each large enough to hold an empty cachet; the powder is deposited in the center of the cachet through a small funnel; the inner edge of an empty cachet is dampened by rubbing it for a moment upon a piece of cotton flannel moistened with water, the moistened cachet is laid upon the one containing the powder so as to enclose it, and the presser, which is armed at its base with three needles and has a spring in the handle, is applied so that the cachet is sealed, and when the spring is released the needles penetrate the edge of the finished cachet sufficiently so that it can be lifted and dropped into the box without touching it with the hands.

Fig. 662



German cachet apparatus

Limousin devised a powder measurer, the construction of which is shown in Fig. 634. The upper view shows the measurer closed, ready for use; the lower view shows how its capacity may be varied to suit the weight of the powder desired. This is done by turning the milled head, which revolves upon the screw which is attached to the disk forming the movable bottom of the cup. A coiled spring aids in pushing the disk outward when it is necessary to lessen the capacity, so that this can be regulated with great exactness. The value of this measurer lies in the fact that it can be used for delivering a more or less compact disk of powder in a cachet without soiling the edges of the latter, and when a large number of cachets of a definite weight are needed, *i.e.*, one gram guarana powders; it can be used as is the seidlitz powder measure (see Fig. 633).

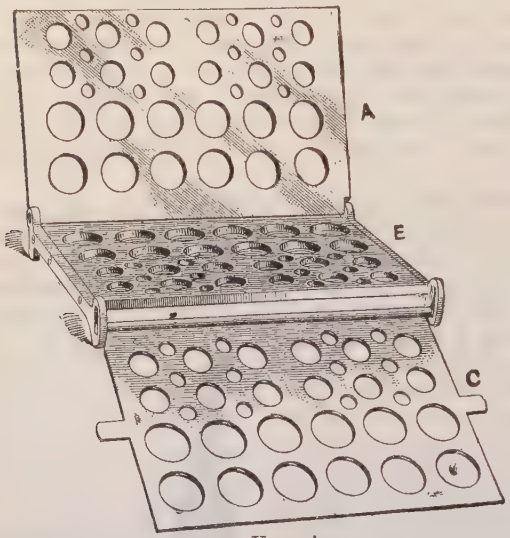
J. M. Grosvenor and Company, of Boston, have introduced an excellent apparatus for dispensing cachets. It is made in a very substantial manner, and consists of three nickeled metal plates hinged together as shown in Fig. 663. The cachets, which are termed "konseals", are made of thinner material than ordinary cachets, and the finished cachet is less bulky and neater in appearance.

The saucer shaped cachets are pressed with the fingers into the inner circles of plate E, and also into those on plate A; plate C is then laid upon plate E, and the medicated powder dropped through the funnel into the cachet. Large doses may be pressed with a thimble furnished for the purpose, and thus smaller cachets may be used than are possible in ordinary apparatus.

When the cachets are filled, the filling plate is lifted and a dampening

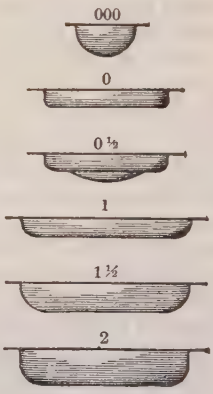
roller passed over the edges of the empty cachet in plate A. The latter is then closed over the bottom plate, and a slight pressure seals the cachet. On opening the apparatus the filled cachets may be easily removed by gently pushing out each one with the finger.

Fig. 663



Konseal apparatus

Fig. 664

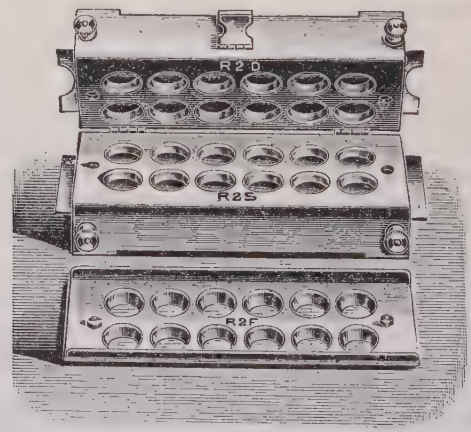


Konseals (exact size)

Fig. 664 shows the exact sizes of the wafer konseals. No. 000 permits the administration of a cachet not larger than a large sized pill.

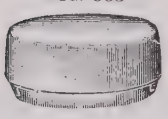
The name "konseals" was adopted by J. M. Grosvenor and Company, as

Fig. 666



Dry seal cachet apparatus

Fig. 665



Dry seal cachet

shorter and better adapted for prescription use than "Morstadt's cachets", which was their original name. They were contrived by Karl Morstadt, of Prague, Austria.

Fig. 665 shows Johann Schmidt's dry seal cachet. The advantage of this form is that there are no "flanges", as in the ordinary cachet. They are made of very thin, elastic wafer sheet; the manner of closing the dry seal cachet resembles that used for "empty" gelatin capsules. The "cap" fits over the body, and no moistening is required, as the pressure forces the cap tightly over the edge of the body containing the powder. The apparatus shown in Fig. 666 is similar in construction to the "konseal" apparatus above described.

It is greatly to be regretted that wafer capsules are not more frequently prescribed. They have many substantial advantages. The substance is rendered tasteless by their use, and yet is easily liberated in the stomach in a pulverulent condition, and this is well known to be the most favorable solid form for solution in the gastric fluids; the knack of swallowing them is easily acquired; the pharmacist has the great advantage of furnishing preparations which are not ready made and the purity of the ingredients can be personally vouched for.

CHAPTER CIII

MASSES, PILLS, AND TROCHES

Massæ—*Masses*

Official pill masses have been discussed in Part III on pages 487 and 488. Several masses are official because of their frequent use in prescriptions in compound pills. They, of course, represent the preliminary stages of pill making and are therefore considered at this point in the preliminary study of pills.

Fig. 667

Pill pestle

In the following pages, under the subject of *pills*, will be found an extensive discussion of the qualities which should be possessed by a pill mass. To secure this condition there must be an application of the principles there fully described. Among the most important factors is the selection of a suitable excipient (see page 1692). Another essential condition for the proper making of a pill mass is the thorough kneading of the mass. On a small scale this is accomplished by the use of a mortar and pestle.

The operator grasps the pill pestle in the hand so that the pestle head rests in the palm of the hand. It must, of course, be a short pill pestle with a flat head (see Fig. 667). He then raises the pestle but rests it against the flat side of the mortar. By now throwing his weight upon the pestle, which, of course, is resting on the mass, the pestle is caused to slide into the mortar but at the same time the mortar's edge is used as a fulcrum. This rends and twists the mass. By throwing the elbow as far as possible from the body and drawing it to the body as the pressure is applied to the pestle, a twisting motion is added which still further assists in kneading the mass. This is repeated until the proper degree of plasticity is attained. It is necessary, of course, to use the correct amount of the appropriate excipient to secure this end.

In making masses upon the large scale mechanical contrivances are necessary to secure a thorough admixture of the various ingredients. The first treatment is with a powerful mixer which thoroughly kneads the mass and incorporates the excipient. For final kneading, to secure the proper consistence the mass is then passed repeatedly through two smooth iron rollers, geared so that they may be made to approach or recede from each other, revolving in opposite directions and at slightly different rates of speed. These may be hollow, so that steam can be introduced inside and thus heated (some masses requiring such treatment). Fig. 668 illustrates Colton's pill mass mixer. This is made of iron and steel, and is capable of kneading a stiff mass.

The other form of mixer made by the J. H. Day Company is shown in Fig. 669. Two steel rollers, which can be set so as to revolve at different distances apart, are secured to a strong iron frame, the operator places the moistened materials that are to be mixed between the rollers, and by continually returning the mass which drops below, it is thoroughly kneaded.

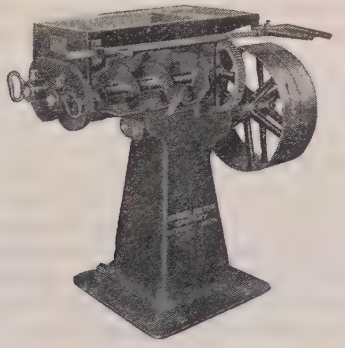
Pilulæ—*Pills*

Pills are small, solid bodies, of a globular, ovoid, or lenticular shape, which are intended to be swallowed and thereby produce medicinal action. Pills, once the most extensively used form of medication, have today been largely replaced by compressed tablets. Substances which are bitter or unpleasant to the taste, if not corrosive or deliquescent, can be administered in this form if the dose is not too large. The ease and rapidity with which pills can be administered, the length of time during which they retain their original activity, their compact form, and their absence of unpleasant taste when coated, are the principal reasons for their use.

The term *parvules* and *granules* has been applied to small sugar-coated pills. *Pellets*, *globules*, or *orbicules* are terms applied to small spheres of sugar, largely used in homeopathic medicine and usually saturated with an alcoholic tincture. A *bolus* is a large pill such as is used in veterinary medicine.

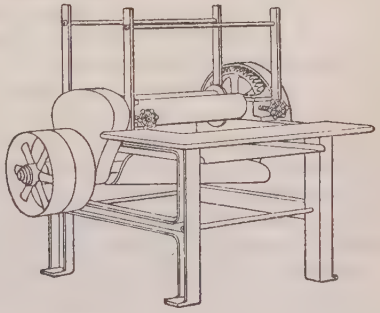
In order to give medicinal substances the requisite shape and consistence to form pills, they must be brought into a soft condition and made into a mass,

Fig. 668



Colton's mass mixer

Fig. 669



Pill mass rollers

generally by the aid of a volatile liquid. The subsequent evaporation of this liquid, or a portion of it, should produce but little change in the form of the pill. As previously stated (page 487), pill masses are sometimes kept in bulk and made into pills when occasion requires. By far the greatest number, however, are made extemporaneously, and the exercise of the knowledge and perception which are necessary in selecting the proper substance to form the mass constitutes one of the most important duties of the pharmacist. To be able always to select the proper excipient requires a thorough knowledge of the physical properties of all the articles of the materia medica which enter into the composition of pill masses.

Forming the Mass—The mass consists of two parts: 1. The active ingredients. 2. The excipient, or the substance used to form the mass and give it the proper consistence. The essential requirements of a pill mass are: 1. *Adhesiveness.* 2. *Firmness.* 3. *Plasticity.*

1. **Adhesiveness**—The mass must be sufficiently adhesive to retain its shape and yet be soft enough to be worked by the fingers or suitable apparatus into the desired form. To enable it to possess adhesiveness, a liquid is usually added to the powdered ingredients, and the selection of this liquid must always depend upon the physical character of the ingredients; in many cases

the latter possess sufficient adhesiveness in themselves if they are moistened with water, and hence the quality is *only developed*, not created, as in the case of powders containing extracts; others, again, are totally devoid of adhesiveness, and sticky substances, like gum, sugar, etc., must be added in sufficient quantity to supply the deficiency. Some substances may be made soft and adhesive by simply heating them, and they regain their original condition when allowed to cool.

2. **Firmness**—The mass must possess sufficient firmness to permit the pills to retain their shape. The condition of adhesiveness is usually dependent upon the addition of a liquid which dissolves *a small portion* of the solid ingredients, and this solution is adhesive enough to enable the mass to be made; but if too much liquid be added, the quality of firmness will be lost, and the pills either cannot be formed at all, or will subsequently run together in the box. The physical properties of the active ingredients of the pill must be thoroughly understood to judge of the proper quantity and kind of excipient to be used to give adhesiveness without losing firmness. The following general rule may serve to guide the operator: *Never employ an excipient alone which is a perfect solvent for the solid substances.* For instance, water should not be used *alone* for making pills of the *soluble* scaled iron salts; for, although the pills may apparently be firm enough when dispensed, they will be very apt in warm weather to run together in the box. If sufficient acacia be used with the water, they can be made to retain their shape.

3. **Plasticity**—The condition of plasticity is a natural result of the possession of a proper degree of adhesiveness and firmness. Many substances may be formed into a mass which will be either adhesive or firm, but unless these conditions are properly balanced, so that the mass can be quickly and easily formed into pills which will retain their shape without flattening, pills cannot be made successfully. Plasticity can generally be secured by thoroughly working or kneading the mass. In this connection see Fig. 669. The choice of excipient is usually left entirely to the pharmacist, and in making the selection care should be taken that, while the pharmaceutical requirements are fulfilled, the proper solubility or disintegrability of the pill in the stomach is not lost sight of.

Choice of the Excipient—An examination of the following list of excipients will probably convey a good idea of their uses. They are divided into two classes, liquid and solid. Liquid excipients are generally preferred, because they are more conveniently added to the powders:

List of Excipients

Liquid

Water	Used only when the ingredients of the pill possess sufficient adhesiveness to be developed by the water
Syrup	An excellent excipient when more adhesiveness is needed than can be afforded by the use of water
Syrup of Acacia	Better than syrup, because it is more adhesive, and can be used in smaller quantity. The objection to its use is that the pills made with it are apt to become very hard, and in some cases they may be practically insoluble in the liquids of the stomach. This excipient is admirably suited to the extemporaneous making of white pills of such alkaloids as strychnine sulphate. If the active ingredient is mixed with a small quantity of lactose it is possible to make a small firm pill which can be dispensed even within a short time, without adhering
Mucilage of Acacia	More adhesive than any of the preceding, but open to the same objection as syrup of acacia
Glycerin	Somewhat adhesive, but very valuable, because its hygroscopic properties prevent the pills made with it from becoming hard. It is rarely advisable to use it alone, however, as the surfaces of the pills often acquire a dampness which attracts the particles of dusting powder
Glucose	A very valuable excipient. It is colorless, very adhesive, and practically non-volatile at ordinary temperatures
Honey	May be used in place of glucose for dark colored masses, but quinine pills are not white when honey is used as the excipient

List of Excipients—*Liquid—Continued*

Extract of Malt	Has the advantages of glucose, but the disadvantage of honey in not being colorless
Glycerite of Starch	Possesses the merits of glycerin, with the adhesiveness of the starch jelly. Its thick consistence is sometimes an inconvenience
Glycerite of Tragacanth	Similar to glycerite of starch. Both of these glycerites find general use as excipients, especially the latter when adhesiveness is required
General Excipient	Suggested by Prof. J. P. Remington as combining the advantages of several of the above (see below)

Solid

Confection of Rose	Useful when a small quantity of an active ingredient is to be made into pills and dilution is necessary, as in pills of strychnine, podophyllin, etc. Its bulkiness is its principal disadvantage for general work
Crumb of Bread (Mica panis)	Valuable for very powerful liquids, like croton oil, volatile oils, etc.
Powdered Althæa	Gives adhesiveness, and is useful as an absorbent, but is bulky
Soap	A very valuable excipient for resinous substances. It increases their solubility, and forms an unexceptionable mass
Rosin Cerate	Valuable for oxidizable substances, resins, etc.
Cacao Butter	Used for pills of potassium permanganate and similiar substances
Petrolatum	Used for oxidizable substances like the two preceding excipients. If used judiciously a small quantity of petrolatum is a valuable aid in developing and retaining the mass character in pills

GENERAL EXCIPIENT FOR PILLS

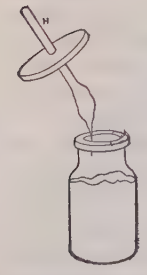
The following excipient is recommended as possessing several advantages. It is a colorless, permanent, very adhesive liquid; the pills made with it are small; and the proportion of glycerin is not large enough to make the surfaces of the pills hygroscopic in an ordinary atmosphere:

Glucose (syrupy)	**4 oz. av.**
Glycerin	**1 oz. av.**
Acacia (powdered)	**90 grains**
Benzoic Acid	**1 grain**

Dissolve the benzoic acid in the glycerin contained in a small tared capsule, add the acacia with stirring, and then the glucose, and allow the mixture to stand until the acacia is dissolved. A *moderate* heat may be applied to hasten solution. The benzoic acid is used as a preservative.

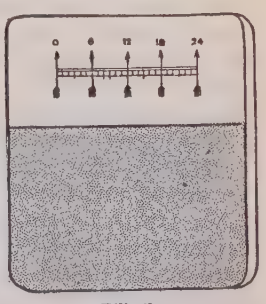
In Fig. 670 a simple but effective excipient bottle is shown. It is made from a plain wide-mouthed bottle; a piece of sheet rubber cloth, such as is used for making washers, is cut into a disk, slightly larger in diameter than the mouth of the bottle; a hole in the center permits the introduction of a round, slightly tapering wooden rod, *H*, or, if preferred, a solid glass rod. It is obvious that as the excipient is used the rod may be slipped down so as always to dip into the excipient a certain distance, and thus the quantity adhering to the end can be easily adjusted. One of the merits of this simple device is that all parts of it can be easily renewed and kept clean.

Fig. 670



Excipient bottle

Fig. 671



Pill tile

Dividing the Mass—Upon the small scale a pill tile may be used for this operation (see Fig. 671). These are usually made of queen's ware or porcelain, but the objection to this material is that some substances will penetrate through the little fissures in the tile and soil it. These are often very difficult to dislodge, and they usually give the tile a dirty appearance in spite of the most thorough washing. Porcelain pill tiles are also so smooth that the pill mass has a tendency to slip as it is rolled. A plate glass pill tile is now available and is far superior to those made from porcelain. They

have the scale graduated by an engraver's wheel, and a little over one-half of the surface ground so that the pill cylinder will not slip. This makes an unexceptionable surface. The pill mass is placed upon the tile and rolled into a cylinder, either with a smooth, flat board or a spatula. It is then placed upon the graduated scale and cut with the spatula into the desired number of pieces; these are afterwards rolled between the fingers into globular pills.

In rolling the pill mass into a cylinder, an ideal roller may be made from a board an inch thick and about 4 by 6 inches in size, having a 2 inch leather strap tacked to the sides so that the entire hand may be pushed beneath it. This gives a heavy, large, and flat surface which will quickly roll out the mass to a pill pipe of even diameter. When the pill pipe has been rolled to the proper length, it is placed over the scale on the pill tile and the place to cut each pill is marked with a spatula, making only a slight depression in the mass. When the pills have all been marked the pill pipe may be cut into the desired number of pills. If this plan is not followed and the individual pill cut without marking the others, the pill pipe will lose its shape and the resulting pills will be of varied sizes.

Fig. 672

Pill spatula

Fig. 672 shows a pill spatula; it has very little "spring", and the end is broad. It is useful in making a mass in a mortar as well as in rolling a pill cylinder. Ordinary steel ointment spatulas, which have the ends broken off or otherwise injured, can often be cut with a file, and the edge smoothed and made into serviceable pill spatulas.

Pill Machines are preferred in making larger quantities of pills; indeed, many pharmacists never use a pill tile, but divide and cut all pills with a machine. A collection of old pill machines well illustrates the development of this useful piece of apparatus. The first improvement over the use of a pill tile and spatula seems to have been the introduction of a cutter which consisted of a series of knives arranged to evenly cut the pill pipe to the desired number of pills. The Michael pill cutter and the Diamond pill cutter were such devices.

The development of the modern pill machine is traced through some of the older wooden machines still to be seen in historical collections. In these a board, having a raised edge of suitable height for the making of the pill pipe, is a separate part of the apparatus. The pill machine itself is much like the modern apparatus except that the grooves are made from hard wood. Such pill machines were very efficient since they possess that peculiar cohesive quality which causes the mass to "roll" under the impact of the cutter.

The next development in the wooden pill machine was the combination of the piping board with the cutter and shaper, practically the machine used today except for the introduction of brass cutters and shapers. The modern pill machine consists of two hardwood boards, one of which is encased in a metal frame (to prevent warping); a brass plate having hemispherical grooves is fastened to one end of the lower board, and a similar plate is adjusted to the upper board, which is furnished with handles at the end; brass guides are attached to the upper board, to cause the cutting surfaces of the grooves on both boards to correspond (see Fig. 673). The pill mass is rolled into a cylinder and laid upon the grooves of the lower board; the upper board is then applied so that the cutting surfaces correspond with those of the lower board, and, by a slight backward and forward motion, with downward pressure, the mass is divided and rolled into perfect pills.

When a smaller number of pills are needed than the full capacity of the cutters indicates, the cylinder is rolled out merely to the length necessary to

make the desired quantity. For general prescription filling, the available pill machine will frequently be found to be of such a size that pills cannot be made on it successfully. In this case, the machine can only be used as a cutter. Each pill machine is made to make a specific size pill and is so marked. This may be 1, 2, or 3 grain, or other sizes. When the pill to be made is the size for which the machine is intended, the skilled pharmacist can turn off perfect pills from the machine without shaping them with the hands.

For making stock pills it is frequently possible to add an additional excipient or filler to insure the making of pills on the machine and this of course

Fig. 673

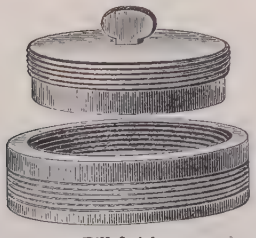
Pill finisher

is done by the manufacturer when pills are made in large quantities. If the pill pipe is of a diameter exactly corresponding to the height of the raised edge of the piping plate of the machine, it is a fair indication that pills can be made on the machine, assuming that the mass is in proper condition.

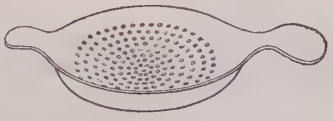
Dusting Powder—To prevent the pill cylinder from sticking to the board or tile, and to lessen the friction, some absorbent powder is dusted upon the surfaces. This may be rice flour, powdered magnesium carbonate, lycopodium, powdered althea, or powdered licorice root. Rice flour is preferable for white pills, because its presence is not easily recognized, and because the cylinder does not slip, as it usually does when lycopodium is used. Small, wide-mouthed

Fig. 675



Pill finisher

Fig. 676



Pill sifter

bottles, fitted with a tooth-powder bottle top, should be provided at the prescription counter for the several dusting powders most frequently employed.

Finishing the Pills—Many efforts have been made to supply effective mechanical devices for finishing pills, yet the fact remains that the pharmacist usually prefers to roll and finish them with his fingers. If a finisher is desired, a level surface having a raised rim may be used, and the pills enclosed and rotated by the adjustable pill finisher shown in Fig. 674, which is turned from hardwood.

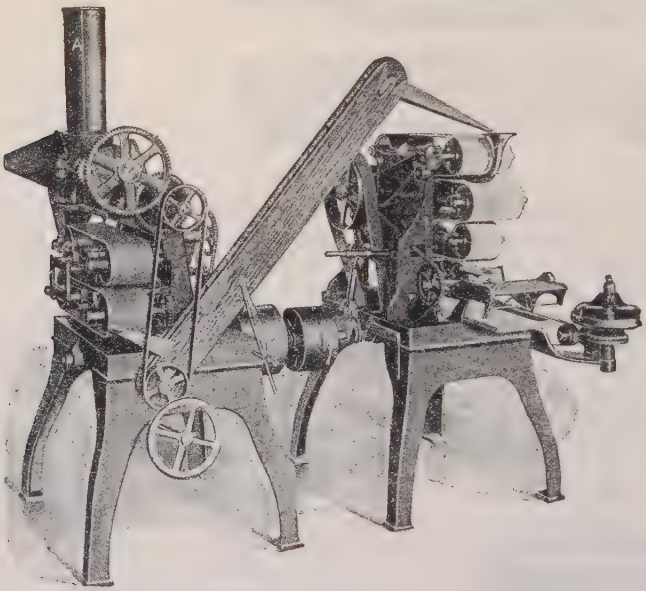
Fig. 675 shows another form of pill finisher which is made of metal. It is less satisfactory than the wooden finisher for its weight must be supported as it is used lest the pills be crushed.

In Fig. 676 is seen a pill sifter; it is made of horn or celluloid and perforated with holes. Pills which are moist are placed in a dusting powder, and when the surface moisture has been absorbed, they are thrown upon the sifter and shaken about gently until freed from adhering superfluous powder.

When large quantities of pills are made, they are usually dried by rolling them in some absorbent powder, spreading them out, and exposing them to dry air.

In Fig. 677 is shown a machine for making pills, manufactured by Arthur Colton, of Detroit. It is, of course, complicated; but when the great number of operations that are required in making pills is considered, the results achieved by this apparatus are marvelous. The illustration shows two

FIG. 677



Colton's modern pill plant

machines; the one on the left, called the ball making machine, makes the mass homogeneous, and delivers it covered with dusting powder in the shape of balls into the hopper of the machine on the right, which is known as the *automata*. As each ball is thus delivered to the piping belts of the automata, a series of operations immediately begins; as it rapidly advances through and toward its destination, it becomes elongated into a strip or pipe; it is rolled many hundred times about its own diameter, and a gentle pressure is given to it as it advances between the belts, sustained from two points of contact; when the pipe is finished, it will have passed through the entire pathway designed for piping, when it now drops on to revolving cutters, where it is divided into pieces of uniform size and weight; these pieces thus cut, drop on to a chute, which conveys them to the entrance of the pill rounding belts; when once drawn in, and between these belts, they are thoroughly rolled, each advancing forward, and by many hundreds side by side, as they go whirling through the automatic finisher; they are now hastened onward until they reach the separator, where a system of sorting is carried on, by which eventu-

ally the perfect pills are retained, and the tailings are rejected. It is possible to make, with the No. 0 automatic pill machine, 864,000 two-grain pills in ten hours' time.

Pulverous Pills—The so-called *pulverous* or *friable pills* are made in a standard coating pan (see Fig. 703). No heat is required. As starters, either rape seed or sugar granules, which are sometimes known as imperials by confectioners, and are identical with the small granules dispensed by homeopathic pharmacists, are used. Of the two kinds of centers or starters, the sugar granule is frequently preferred, as it becomes indistinguishable from the pill when made. The rape seed, on the other hand, can be detected when the pill is broken open.

The starters are placed in the pan and an application of white paraffin oil is added; the powdered drug is then sifted or sprinkled on the oiled centers as they revolve. The powder adheres to the centers and successive applications of oil and powdered drug are added until the pills are built up to the desired size. It is necessary during the process to remove the pills from time to time and screen out the larger ones, putting back the smaller in the pan until they are all brought up to an even size. When the pills are built up to the proper size the oil can be removed by placing them in a drying closet on absorbent paper which will absorb the oil as it sweats out. Some manufacturers prefer to remove the oil by placing the pills in a bath of carbon tetrachloride, which dissolves the oil. Pulverous pills can be sugar or chocolate coated in the usual manner. The equipment consists of a standard coating pan and an assortment of perforated zinc screens. For the extensive production of pulverous pills special wooden tubs, four or five feet in diameter, are used in place of the standard coating pan. These tubs are mounted on the regular coating pan frames.

Dispensing Pills—Pills are usually dispensed in flat, circular or square boxes. These should be made so shallow that the pills cannot lie on top of one another. Square pill boxes (see Fig. 678) are preferred to round boxes for several reasons, the principal one being that a square label can be used. This can be trimmed more neatly and quickly than a round label, can be written upon by a typewriter more satisfactorily, and, in the opinion of many pharmacists of taste, looks better. A small quantity of dusting powder should be placed in the box to prevent the adhesion of freshly made pills. The use of the homeopathic vial, fitted with a screw top, is becoming so general for the dispensing of machine-made pills, tablets, and capsules that they are sometimes employed for freshly made pills. This is especially true of small granules, such as pills of strychnine sulphate. When dispensed in this way the fresh pills must be very firm so that they will not adhere.

Trochisci—*Troches*

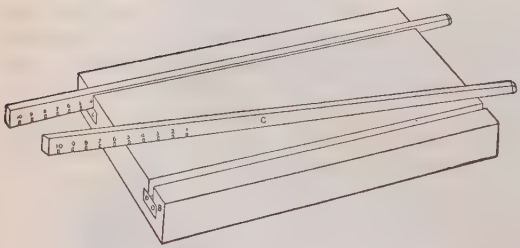
The official formulas for troches will be found on pages 498 to 499, in Part III. In this section under Magistral Pharmacy a general consideration will be given to the methods for preparing troches in a retail drug store or on a small scale by manufacturers. Special formulas for troches are also occasionally prescribed and are discussed here.

Troches, or lozenges, also known as pastilles and, when cylindrical or

rod shaped, as a *bacillules*, are solid, discoid or cylindrical masses, consisting chiefly of medicinal powders, sugar, and mucilage. They are intended to be used by placing them in the mouth and permitting them to remain until, through slow solution or disintegration, their purpose of mild medication is effected. It is obvious that very powerful or disagreeable remedies cannot be administered in this way. The formation of the "lozenge mass" is the most important part of the operation. The dry powders must be made into a tenacious mass which possesses sufficient plasticity to enable it to be rolled into a flat cake without crumbling. It must not retain moisture so long as to occasion too much delay in drying the troches, and the troches must not be brittle through want of sufficient adhesiveness. Mucilage of tragacanth has been found best to bring about the adhesion of the powders.

Making the Mass—The best method of making the mass is first to prepare the mucilage according to the formula, and, having mixed and sifted the powders, add sufficient mucilage to make a mass of the proper consistence.

Fig. 679



Slocum's lozenge board

Fig. 680

Lozenge punch

Fig. 681

Lozenge punch (steel cutter)

The quantity always depends upon the character of the powder. If the latter is absorbent, more mucilage is required than if the powder is made up largely of extracts. The usual method of mixing powdered tragacanth or acacia with the dry powders, and then trusting to the addition of the right proportion of water, is generally disappointing in the hands of the inexperienced, almost invariably producing too moist a mass. Upon the large scale the manufacturer employs a mixing machine to form the mass; upon the small scale the pharmacist uses the mortar and pestle.

Rolling the Mass—When the mass is made, it must be formed into a flat cake by placing it upon a hard, level, dusted surface and rolling it with a cylindrical roller. The thickness of the cake determines the weight of the lozenge, and hence it is more exact to have some means of adjusting the thickness. In Slocum's lozenge board (see Fig. 679) this is ingeniously effected by the use of tapering oak strips, *C*, which slide in inclined furrows; the handles of the strips are graduated, having saw kerfs at regular intervals; the brass plate, *B*, permits these to be accurately adjusted and held, so that both strips project uniformly above the board. By pushing both strips forward, greater thickness of the lozenge cake is secured.

Effort has been made in the N. F. to make troches of the uniform weight of 1 Gm. Although the amount of medication varies, sufficient filler is added to make up the necessary weight. This makes it possible for the manufacturer of troches to prepare a lozenge board of hard wood, and perfectly level, such as a "bread board", and permanently fasten upon it narrow strips of wood of the exact thickness of the troche. This can be determined by a trial in which the lozenge mass is rolled out upon the board and the lozenges punched out with the cutter when the mass is at varying thicknesses to determine the exact thickness which will produce a 1 Gm. troche, when made by the punch to be employed. Uniformity in thickness of troches also has the advantage of uniformity in the size of the box used for their sale.

Cutting the Troches—Troches are cut by cylindrical or conical punches, often made of tinned iron, as shown in Fig. 680, but preferably of steel. Fig.

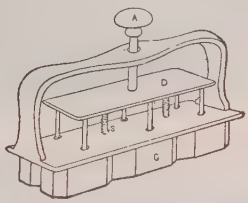
Lozenge cutter, with die

Fig. 683



Lozenge cutter

Fig. 684

Lozenge cutter (end view)

Fig. 685

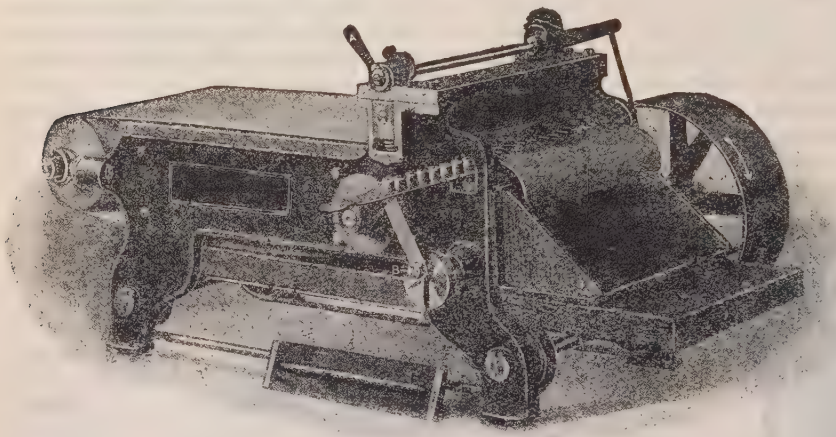
Lozenge cutter

681 shows a very good punch, having a hardened steel octagonal cutter, *C*, soldered to a hollow conical handle, *M*. Fig. 682 represents a very complete lozenge cutter with a circular die, which stamps a letter upon a lozenge in addition to cutting it. It is made very substantially, and is accompanied by a cutter and a die for oval lozenges. Fig. 683 shows an excellent cutter which accurately cuts six lozenges at once. It was devised by a Western pharmacist. Fig. 684 gives the end view. The cutter is placed upon the soft mass and pressed down until the edges touch the board. By pressing upon the handle, *A*, the lozenges are forced out of the cutters, the springs, *S*, causing the pushers to resume their original position. Fig. 685 illustrates a type of lozenge punch which was specially made and which is admirably suited to the preparation of lozenges on a comparatively large scale. It embodies the advantages of the single punch (see Fig. 680) in that troches as they are cut are forced into the

cylinders of the cutter until they are full when they may all be dumped upon a suitable drying tray without further handling.

Fig. 686 shows Colton's lozenge cutting machine. The mass, having been previously rolled into a flat cake of the desired thickness, is placed upon the moving rubber belt, which carries it forward to a finishing roller which gives

Fig. 686



Colton's lozenge cutting machine

it the necessary evenness of surface; it then passes under the tapering cutters, and the lozenges drop downward to a tray or receiver.

When troches have been made by the use of a punch they must be thoroughly dried before boxing, else they are likely to mold.
